Identical observations were made on patients who received digitalis and those from whom digitalis was withheld. The usual clinical and laboratory observations were taken, such as temperature, pulse, respirations and blood pressure, urinalysis and Wassermann reaction, and frequently morphologic and chemical examination of the blood. In addition, every patient was electrocardiographed daily during the febrile period, and every other day thereafter. A control tracing was taken on all digitalis-treated patients before any digitalis was administered. A total of 2,668 electrocardiograms were taken in the first year, and 3,369 in the second. Of the 835 patients studied in both years, 625 were electrocardiographed three or more times, 153 had one or two tracings, and 57, or less than one tenth, died before any tracings were taken at all.

A special staff was appointed to carry out the work along the method outlined. A full-time fellow was in resident charge of the work each year,[9] and was assisted by an electrocardiographic technician and a diener. This staff was working in addition to the staff then studying the serum treatment, and to the regular intern staff of the hospital.

DIGITALIS

Previous to the beginning of the investigation, different preparations of digitalis had been used in the three services. In the Columbia University service, the regular Bellevue Hospital preparation of digitalis was used. In the Cornell University Service, a preparation which we will call B was in use. This had been standardized by the manufacturer and was said to have a potency of 66 mg. equivalent to one cat unit by the cat unit method of Hatcher. In the New York University Division a preparation standardized by the manufacturer was in use which was said to have a potency of 100 mg. equivalent to one cat unit. These preparations had been in routine use in the wards and at this time there was no reason to doubt the reliability of the standardization. However, as it was desired to use a standardized preparation in all three services it was decided to discontinue the use of the unstandardized hospital digitalis in the Columbia Division and to use in its stead on this as well as in the Cornell Service preparation B, and to use in the New York University service a preparation which we will call A.

On its being noted that there was a high incidence of toxic signs for patients treated with the B preparation, it was found that this specimen of digitalis was approximately twice as active as the manufacturer had stated, in terms of cat unit potency. Reports dealing with the standardization of this preparation have been published.[10] When the error in standardization had been proved, a third noncommercial standardized preparation of digitalis was administered to patients in all divisions. This preparation, designated preparation G, had a potency of 100 mg. equivalent to one cat unit. While this occurrence resulted in unfortunately high dosage to a number of patients, it enabled us to study three groups: patients receiving too little dosage, optimum dosage (as far as could be determined) and high dosage.

DOSAGE

It was realized that in acute disease such as pneumonia, patients have to receive their digitalis rapidly. At the same time it was felt that the production of toxic effects should be prevented if possible. For this reason it was decided to give the digitalis in divided dosage, in no case giving a patient a digitalizing dose of more than the amount of 0.15 cat unit per pound of body weight, and to stop the administration of the drug on the appearance of any suggestive toxic symptom even though the full calculated amount had not been given. During the first year the dose was divided into parts approximating 30, 30, 15, 15 and 10 per cent of the estimated dose and these were given at intervals of six hours, the last dose (when given) being given about twenty-four hours after the first. As it was deemed unwise and unnecessary to weigh these patients, they were divided roughly into three groups, those who appeared to weigh less than 125 pounds (56.7 Kg.), those weighing between 125 and 175 pounds (79.4 Kg.) and those weighing over 175 pounds.

Because of the incidence of toxic signs, especially vomiting and the higher grades of heart block, in the digitalis-treated cases before the specimens were restandardized, it was decided, in the second year of the investigation, to reduce the dosage. Patients were then divided into two weight groups instead of three, those weighing above and below 150 pounds (68 Kg.). The lighter weight group received a total digitalizing dose of ten cat units, or 1 Gm., and the heavier 12.5 cat units, or 1.25 Gm. This was administered in three doses, the first 50 per cent of the total, the second 25 per cent, given twelve to eighteen hours after the first, and the third dose, 25 per cent, given after another interval of from six to eight hours. This dose compares closely with that given by Cohn and Jamieson.[1] They had observed with 0.8 Gm. definite digitalis effects on the electrocardiogram in pneumonia, and their usual dosage[2] was between 1 and 2 Gm. Hart[6] also used a similar dosage in the treatment of influenzal pneumonia, giving 25 minims (1.5 cc.) of the tincture every four to six hours for six doses, or a total of the equivalent of 1 Gm. in twenty-four hours, and 24 minims daily thereafter, or the equivalent of 0.3 Gm. Stone[8] used a dosage of 4 cc. of tincture digitalis given every four hours for six doses, or a total dose the equivalent of 1.6 Gm. of powdered leaf in twenty-four hours, and no daily maintenance dose.

---

[9] The Fellows in Medicine in immediate charge of the digitalis investigation were J. Allen Yager, M.D., during the first year; Janet G. Travell, M.D., the second year and Margery Shearer, M.D., during the third year. The authors wish to express their appreciation for the invaluable services rendered by the Fellows.

[10] Wyckoff, John; and Gold, Harry: A Dangerous Preparation of Digitalis, J. A. M. A. 94: 626 (March 1) 1930. Wyckoff, John; Gold, Harry; and Travell, Janet G.: The Importance of Differences in the Potency of Digitalis in Clinical Practice, Am. Heart J. 5: 401-411 (April) 1930.

In our investigation, a daily maintenance dose of two cat units was given in both years. This was administered in a single dose each morning, and was discontinued when the temperature became normal or if toxic signs developed.

It was particularly difficult to determine proper dosage from the experience of others because most investigators either used no standardized preparation of digitalis, or, if a standardized preparation were used, the fact that it had been standardized was noted without estimation of its potency.

Table 1.—*Comparative Mortality of Digitalis Untreated and Treated Patients for the First and Second Years of the Investigation* *

	No Digitalis			Digitalis			
Year	Number of Patients	Number Died	Mortality, per Cent	Number of Patients	Number Died	Mortality, per Cent	Difference in Mortality
1	197	68	34.5	158	67	42.4	7.9
2	207	68	32.9	180	73	40.6	7.7
1 and 2	404	136	33.7	338	140	41.4	7.7

* In tables 1, 2, 3, 4 and 6, patients discharged at their own risk, patients in the C and D (digitalis treated) series who received no digitalis, and deaths within twenty-four hours after admission have been excluded.

In all, 834 cases were studied. A few of these patients were discharged from the hospital at their own risk on the request of responsible relatives; several others in the groups scheduled to receive digitalis, through error, received none. These, and all patients dying within twenty-four hours after admission, were excluded from the tabulations. There remained 742 patients.

Table 1 shows the gross results of the study. It must be remembered that a difference of 7.7 per cent in a mortality of 33.7 per cent means an increase in mortality of more than one fifth. The mortality of the digitalis group and the group receiving no digitalis is consistent for both years. This is particularly noteworthy because during the second year the dose was greatly reduced, as has been stated. A later study, however, shows that this high mortality occurs in patients getting the larger doses, even in the second year.

Table 2.—*Mortality of Males and Females for Digitalis Untreated and Treated Patients*

	No Digitalis			Digitalis			
Sex	Number of Patients	Number Died	Mortality, per Cent	Number of Patients	Number Died	Mortality, per Cent	Difference in Mortality
Male	357	123	34.5	299	125	41.8	7.3
Female	47	13	27.7	39	15	38.5	10.8

The sex distribution was preponderatingly male for the series, but table 2 shows that the sex ratio was consistent both in the group receiving digitalis and in that from which the drug was withheld. The female series is so small that it is doubtful whether the difference of 3.5 per cent greater mortality among the women receiving digitalis is of significance.

Table 3.—*Mortality of Age Groups for Digitalis Untreated and Treated Patients*

	No Digitalis			Digitalis			
Age Group in Years	Number of Patients	Number Died	Mortality, per Cent	Number of Patients	Number Died	Mortality, per Cent	Difference in Mortality
10 to 29	94	15	16.0	73	19	26.0	10.0
30 to 39	109	30	27.5	76	25	32.9	5.4
40 to 49	99	40	40.4	99	44	44.4	4.0
50 plus	102	51	50.0	90	52	57.8	7.8
Totals	404	136	33.7	333	140	41.4	7.7

Table 3 shows age distribution in the groups receiving and not receiving digitalis. The distribution is extremely consistent in the patients who did not take this medicine; in the group which did receive digitalis there are about 6 per cent more over the age of 40 than under. Brooks[11] advises routine digitalis therapy in older patients. In this series, digitalis did not reduce the mortality in the older age groups; the patients over 50 receiving digitalis showed a mortality of 7.8 per cent higher than patients in the same age group not receiving the drug.

It is known that the mortality in pneumonia is different in the various types. Patients with type I pneumonia have a relatively low mortality and those with type II a very large mortality. Table 4 compares the type incidence in the two groups. It is shown that it is consistent in both, and that the difference in mortality in the group receiving and not receiving digitalis cannot be due to a preponderance of a low mortality type such as type I or of a high mortality type such as type II occurring in one of the two groups. It shows that the mortality is always higher in the group receiving digitalis except for type II; patients in type II receiving digitalis actually had a mortality of 2.3 per cent lower than patients not receiving it.

Table 4.—*Mortality of Pneumococcus Types for Digitalis Untreated and Treated Cases*

	No Digitalis			Digitalis			
Type	Number of Patients	Number Died	Mortality, per Cent	Number of Patients	Number Died	Mortality, per Cent	Difference in Mortality
I	98	22	22.4	66	23	34.8	12.2
II	130	62	47.7	108	49	45.4	—2.3
III	28	9	32.1	25	12	48.0	15.9
IV to XIII and unclassified	135	33	24.4	128	50	39.1	14.7
Miscellaneous	13	10	....	11	6	....	....
Total	404	136	33.7	338	140	41.4	7.7

We have been unable to explain this inconsistency in otherwise consistent results. Our type II patients had similar age distribution in the two groups and the group receiving digitalis received it in the same dosage as did the patients having other types of pneumonia.

Our cases were carefully watched and toxic symptoms, such as vomiting, second, third or fourth stage

---

11. Brooks, Harlow: The Treatment of the Patient with Lobar Pneumonia, Internat. Clin. 4: 201-215 (Dec.) 1927.

heart block and coupled rhythm, occurred to some degree in 75 of the 338 cases. As might be expected, 65 of these were noted in the 142 patients receiving digitalis B (the improperly standardized preparation), and in only 5 patients of the 93 receiving digitalis A, and in 5 of the 109 patients receiving digitalis G. These facts will be discussed later.

It was pointed out by Cohn and Jamieson[1] that, in auricular fibrillation and flutter, greatest benefit could be expected from digitalis therapy in pneumonia. Table 5 shows that in 835 cases there were 33 cases of either auricular fibrillation or flutter. Seventeen patients received no digitalis and 16 received it. Of the patients who received no digitalis, 9 died, a mortality of 52.9 per cent. Of the 16 patients who received digitalis, 14 died, a mortality of 87.5 per cent. In this paper these facts are simply being presented. A more detailed analysis of these cases and those now being studied will be presented at a later time.

Table 5.—*Mortality and Incidence of Auricular Fibrillation and Flutter* *

Auricular Fibrillation and Flutter	No Digitalis (429 Patients)	Digitalis (406 Patients)	Total All Patients (835 Pat ents)
Number of patients	17	16	33
Incidence in series	4.0%	3.9%	4.0%
Number died	9	14	23
Mortality	52.9%	87.5%	69.7%

* The average dose of digitalis per patient for the digitalis treated group was 1.17 Gm.

Stone, Phillips and Bliss[7] discuss the necessity of considering separately patients the course of whose disease is associated with pneumococcal complications such as empyema, endocarditis, pericarditis, arthritis and meningitis from those not so associated. In order that we might do this, table 6 was prepared. This table shows that 27 of the digitalis treated patients had such complications; 19 died, a mortality of 70.4 per cent. There were 24 patients not receiving digitalis; 14 died, a mortality of 58.3 per cent, a difference in mortality of 12.1 per cent in favor of patients not receiving digitalis.

Table 6.—*Mortality of the General Series Except Patients with Pneumococcal Complications for Digitalis and No Digitalis Groups*

	No Digitalis			Digitalis			
Group	Number of Patients	Number Died	Mortality, per Cent	Number of Patients	Number Died	Mortality, per Cent	Difference in Mortality
General series	404	136	33.7	338	140	41.4	7.7
Pneumococcal complications	24	14	58.3	27	19	70 4	12.1
Series excluding patients with pneumococcal complications	380	122	32.1	311	121	38.9	6.8

A further study along this line is shown in table 7, which compares the mortality of patients with negative and with positive blood cultures. Of 53 patients with positive blood cultures who received digitalis, 42 died, a mortality of 79.2 per cent. Of 54 patients with positive blood culture who did not receive digitalis, 43 died, a mortality of 79.6 per cent, a difference of only 0.4 per cent in patients having positive blood cultures. On the other hand, of 116 patients having negative blood cultures and receiving digitalis, 40 died, a mortality of 34.5 per cent, while of 124 patients with negative blood cultures who did not receive digitalis, 25 died, a mortality of 20.2 per cent. This shows a 14.3 per cent lower mortality for those who did not receive digitalis.

Table 7.—*Comparative Mortality of Patients with Negative and Positive Blood Cultures for Digitalis and No Digitalis Groups* *

	No Digitalis			Digitalis			
Blood Culture	Number of Patients	Number Died	Mortality, per Cent	Number of Patients	Number Died	Mortality, per Cent	Difference in Mortality
Positive	54	43	79.6	53	42	79 2	—0.4
Negative	124	25	20.2	116	40	34.5	14.3

* Patients discharged at their own risk, and patients in the C and D (digitalis treated) series who received no digitalis have been excluded.

Table 8 compares the mortality of patients receiving the three preparations of digitalis and of patients taking none. It will be seen that the average cat unit dose of preparations A and G was 18.4 and 10.4, respectively, while that for preparation B, the misbranded one, was 31.3. It shows that the mortality rate of groups A and G are almost identical, 36.7 and 37.7 per cent, respectively, and that the mortality rate for patients receiving digitalis B is approximately 10 per cent higher, 47.2 per cent.

Table 8.—*Comparative Mortality of Patients Receiving Digitalis A, B and G and of Patients Receiving No Digitalis*

Digitalis	Average Cat Unit Dose	Number of Patients	Number Died	Mortality, per Cent
Specimen B	31.3	142	67	47.2
Specimen A	18.4	90	33	36.7
Specimen G	10.4	106	40	37.7
No digitalis	....	404	136	33.7

We expected an analysis of the latter group to show that the high mortality was due to the toxic effect of digitalis as shown by other evidences of digitalis toxicity, in which case, as is obvious, all patients receiving the drug in toxic dosage should not be considered in the investigation. Much to our surprise, however, we found that the highest mortality came in the group of cases that did not show any of the known toxic symptoms of digitalis but who had received large dosage of the drug. In fact, the analysis of table 9 shows that patients developing signs of digitalis toxicity had not only a lower mortality (27.1 per cent) than patients receiving digitalis and developing no toxic signs (45.1 per cent), but even a lower mortality than patients receiving no digitalis whatever (33.7 per cent).

Table 9.—*Mortality of Toxic and Nontoxic Cases*

Toxic	Number of Patients	Number Died	Mortality, per Cent	Average Cat Unit Dose
Specimen B	61	15	24.6	32 2 C. U.
Specimen A	5	2	40.0*	17.4
Specimen G	4	2	50.0*	8.0
All preparations	70	19	27.1	
Nontoxic				
Specimen B	81	52	64.2	30.6 C. U.
	85	31	36.5	18.5
	102	38	37.3	10.5
	268	121	45.1	

* Numbers too small to be of any significance.

The possibility was considered of having included in the group receiving a large dosage of digitalis a number of patients who had actually received insufficient dosage of digitalis; in table 10 the nontoxic cases are further divided into those which showed positive digitalis effects on the T wave or the P-R interval in the electrocardiogram and those which showed no such effects. This table shows definitely that the higher mortality in the nontoxic digitalis group cannot be attributed to insufficient digitalis, because in the twenty-two patients who did not receive enough digitalis to produce an effect in the electrocardiogram, the mortality is low.

TABLE 10.—*Mortality According to Digitalis Effect All Preparations—Nontoxic Cases*

	Number of Patients	Died	Mortality
Digitalis effect............	246	115	46.7%
No digitalis effect........	22	6	27.3%

Because different preparations were given at various periods of the year and in different wards we have in table 11 compared the mortality rates of patients treated with each preparation of digitalis with those of the untreated patients for the same periods and on the same divisions. Thus the digitalis A cases are compared with the nondigitalis cases in the Third Medical Division up to Jan. 31, 1929, the digitalis B cases with nondigitalis cases of the First and Second Medical Divisions up to Jan. 31, 1929, and cases treated with digitalis G with the nondigitalis cases in all medical divisions after Jan. 31, 1929.

In this table an arbitrary grouping of the nondigitalis groups shows a range in the mortalities of these samples of from 30.8 to 36.4 per cent, a range of 5.6 per cent. The patients in the group receiving digitalis specimen A have a 0.3 per cent higher mortality, those receiving digitalis specimen G 6.9 per cent higher mortality and those receiving digitalis specimen B a 13.3 per cent higher mortality than a group treated under identical conditions and time, but receiving no digitalis.

TABLE 11.—*Comparative Mortality of Digitalis Untreated and Treated Patients According to Preparation Used*

	No Digitalis			Digitalis			
Period	Total	Died	Mortality	Preparation	Total	Died	Mortality
Divisions I and II; until Jan. 31, 1929	177	60	33.9%	Specimen B	142	67	47.2%
Division III; until Jan. 31, 1929	110	40	36.4%	Specimen A	90	33	36.7%
Divisions I, II and III; after Jan. 31, 1929	117	36	30.8%	Specimen G	106	40	37.7%
Entire period..........	404	136	33.7%	All preparations	338	140	41.4%

COMMENT

In the tables presented, in all categories except patients with type II pneumonia there was an increase in the mortality among patients receiving digitalis as contrasted with those who did not receive the drug. When these tables are reanalyzed, the patients receiving digitalis being grouped into those who received toxic dosage of the drug, those who received a digitalis effect but no toxic dosage, and those who showed no evidence of digitalis effect, it would appear that patients receiving enough digitalis to produce an effect on the electrocardiogram but not enough to produce toxic signs had an increased mortality, but on still further analysis it was shown that the increased mortality occurred in that group which received the largest amount of digitalis, irrespective of whether or not they showed toxic digitalis signs. Furthermore there is no evidence, even among the group who received what might be termed optimum dosage, that routine digitalis therapy could reduce mortality. This was true even among a small group of patients with auricular fibrillation who were studied.

In the giving of digitalis to patients with congestive heart failure in organic heart disease there are three guides useful in controlling medication: first, certain actions on cardiac mechanism, as shown clinically by ventricular slowing, or graphically by an increased P-R interval or changes in the T wave; second, the clearing up of signs of heart failure, and, third, the appearance of certain mild toxic phenomena. In pneumonia, on the other hand, except for the lowering of rate in patients who have developed auricular fibrillation there are practically no signs of digitalis effects other than those described in the electrocardiogram by Cohn and Jamieson[1] and toxic effects. The clearing up of signs of heart failure can never be used as a guide.

Since in the congestive heart failure of heart disease untoward effects are rarely if ever seen in patients who have not first developed mild symptoms of toxicity, it had previously been our belief that in patients with pneumonia receiving digitalis careful observation would give evidence of mild toxic digitalis effect before any damage could be done by the drug. This does not seem to be true in the light of our experience. In our cases there is a definite increase in the mortality of patients who received large doses of digitalis but who had none of the clinical symptoms of either early or late digitalis toxemia. May it not be that because of the effects of pneumonia toxin digitalis may produce death not infrequently without any warning signs of the usual clinical manifestations of mild or profound toxicity? If this is true, extraordinary care should be used in the giving of digitalis in pneumonia, for the dose cannot be guided except by an arbitrary limitation of the total dosage.

SUMMARY

There is no evidence that routine digitalis therapy in lobar pneumonia results in a lowered mortality.

In pneumonia patients with sinus rhythm the only consistent evidences of digitalis effect are electrocardiographic changes and mild toxic effects.

About 95 per cent of patients have sinus rhythm throughout the course of lobar pneumonia.

Clinical symptoms of digitalis toxicity are not a sufficient guide in digitalis therapy in lobar pneumonia to prevent increase in mortality when the drug is used. The amount of the drug given is a better guide.

When given in dosage too small to show any effect, it causes no changes in mortality. When given in dosage comparable with the amount usually needed in the treatment of heart failure, it produces effect on the P-R interval and T wave of the electrocardiogram but causes little change in mortality.

Digitalis may perhaps be life saving in an occasional patient in whom there is auricular fibrillation or auricular flutter.

Auricular fibrillation and auricular flutter occur rarely, in less than 5 per cent of all cases. Patients developing this condition frequently recover without digitalis.

It is believed by us that the routine giving of digitalis to patients with lobar pneumonia is dangerous.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. GOLD AND DEGRAFF AND DRS. WYCKOFF, DU BOIS AND WOODRUFF

Dr. Frank N. Wilson, Ann Arbor, Mich.: There has been a considerable difference of opinion among cardiologists regarding the advisability of giving digitalis in a routine manner to patients with pneumonia. Those who favored its administration advanced the following arguments: Digitalis has the same effect on the T-wave and the P-R interval of the electrocardiogram in pneumonia that it has in heart disease and in health (Cohn); consequently, pneumonia does not prevent it from producing its characteristic effects on the heart muscle. Auricular fibrillation is not uncommon in pneumonia. The response to digitalis is the same as in fibrillation due to other causes (Cohn). This disturbance constitutes an extra hazard which may be greatly diminished or eliminated by the routine administration of the drug. Roentgen studies have shown that the heart dilates in pneumonia. The dilatation is prevented or diminished by giving digitalis (Levy). The dilatation suggests that the heart muscle is weak; digitalis apparently improves its condition. Those who opposed the routine administration of digitalis in pneumonia did so on the ground that it had not been clearly shown that cardiac weakness played an important rôle in the mortality rate and that, as a general principle, drugs should not be given as a routine but only when the need for them became apparent. Those who favored giving the drug had, perhaps, a little the best of the argument; there was, however, something to be said on the other side. In view of the work which Drs. Wyckoff, Du Bois and Woodruff have reported, it is difficult, so it seems to me, to escape the conclusion that the routine administration of digitalis in pneumonia is dangerous. I should like to ask the authors their opinion regarding patients who have some measure of cardiac failure before they develop pneumonia; whether or not they advocate the giving of digitalis to these. If I understood Drs. Gold and DeGraff correctly, they dealt exclusively with patients who had auricular fibrillation. In such patients digitalis has a profound effect on the heart rate. This effect, which is a very important one in these patients, is due chiefly, not entirely, to the effect of the drug on vagal tone. In patients with normal rhythm, this effect is negligible. It is not known that the vagal and muscular effects of the drug are always parallel. Consequently, conclusions based on the effect of digitalis in one group of patients cannot, so it seems to me, be applied to the other without reservations.

Dr. A. A. Herold, Shreveport, La.: In 1909 I read a paper before our state society in which I advocated the use of digitalis in pneumonia based on the fact that in numerous autopsies we found dilatation of the heart the cause of death in pneumonia. My plea at that time was to give the digitalis and feel the way both by blood pressure readings and by pulse rate, and give it, as Dr. Wilson brought out in summarizing the arguments pro and con, before it is too late, because if one waits for the fibrillation or the dilatation to start or what not and then starts digitalis, there will not be time to get the digitalis effect. That is a point which I would like to ask the authors to bring out in closing. How can a quick digitalis effect be obtained in those cases in which it is indicated if it is not going to be given in a routine manner?

Dr. Harold E. B. Pardee, New York: Drs. Gold and DeGraff have added an important fact to the knowledge of digitalis: the dose to maintain an effect need not be as large as the dose which was necessary to produce that effect. However, in its application to the therapeutics of digitalis, I do not believe that this is so important as it is from the point of view of pharmacology. In treating patients one is usually concerned with maintaining effects against rather considerable odds, and I would feel that in treating a patient it would always be necessary to give the patient the dose which would be close to his therapeutic limit before I would be sure that I had produced the best results of which the drug was capable. In the interpretation of the heart rate of patients with auricular fibrillation, certain sources of error arise, and these have a bearing on the conclusions of Drs. Gold and DeGraff. The chief source of error is that certain patients may have the same heart rate at rest and yet after exercise the heart rate will be increased differently, thereby indicating a different degree of digitalis effect. This may be in part due to an *idiosyncrasy* of the patient but it depends also on the degree of the digitalis effect. If a patient should be found with a heart rate when at rest of 75, which went up to 110 after a certain amount of effort, that patient given more digitalis might still have a heart rate when at rest of approximately 75, and yet after the same effort the rate would increase only to 90. Obviously the patient is in a much better physiologic condition when his heart rate goes only to 90 after exercise than he is when it goes to a higher rate, because exercise occurs constantly in his daily life. The heart rate cannot, of course, be taken as an indication of the degree of cardiac reserve. I believe that these two things also are so independent, in a considerable number of patients, that one must be wary how one draws conclusions from the heart rate as to the degree of cardiac reserve. Therefore, to maintain a constant heart rate when at rest does not necessarily mean that cardiac efficiency is being maintained at a constant level or that the same therapeutic effect of digitalis is being obtained.

Dr. Oscar W. Bethea, New Orleans: I was interested to note that the work on auricular fibrillation substantiated the work of the English physicians in which Lewis, following McKenzie, grouped the auricular fibrillation cases into four divisions: those that would remain normal when reduced to normal, without digitalis; those in which small doses of digitalis would maintain the effect; those in which large doses of digitalis were necessary to maintain the effect, and those in which no dose of digitalis would maintain the effect. I sometimes feel that we of this generation think that we discovered the large dose of this drug. I was interested recently to note that the elder Wood thirty odd years ago, in the United States Dispensatory, spoke of a patient that had received a teaspoonful of tincture of digitalis three times a day for a long period of years and had been maintained apparently in a state of perfect health. With regard to the treatment of pneumonia, I was highly delighted to note the trend of the statistics that were presented to us, particularly as in my paper tomorrow on the treatment of pneumonia, I protest most earnestly against the routine administration of digitalis.

Dr. Harry Gold, New York: In reply to Dr. Wilson's remarks, I wish to say that we used only patients with auricular fibrillation in our study. Slowing of the heart rate in these patients is not due solely to stimulation of the vagus center. The evidence for that was presented many years ago by the results obtained after paralysis of the vagi by atropine in digitalized patients. Furthermore, slowing of the heart rate is only one element in the action of digitalis, and improvement that results in patients with auricular fibrillation is not due merely to slowing of the heart rate. The work of recent years has shown beyond a shadow of doubt that there is no fundamental difference between patients with a regular sinus rhythm and those with auricular fibrillation in the response of their congestive heart failure to digitalis. This suggests that the principles laid down in this study should apply to patients with a regular sinus rhythm. We were studying the response of heart failure to digitalis. Changes in the heart rate, however, yield the most striking graphic representation of the results and that is why we used the heart rate in our illustrations. We stated throughout that these patients improved as completely as possible and that when we gave them twice as much digitalis as they had at the beginning they did not show any greater improvement. I do not know what else one can do to ascertain that the full therapeutic effects of digitalis have been produced. Dr. Pardee's remarks on the relation between dosage and the response of the heart rate to effort are *not* supported by any evidence based on controlled studies. If a patient is given 3 grains (0.2 Gm.) of digitalis daily and marked improvement in the *symptoms and signs of failure results*, and if he is then given 6 grains (0.4 Gm.) daily with no signs of greater beneficial effects, it is probable that he does not need the 6 grains, but that 3 grains is sufficient. Dr. Pardee states that he prefers to give the larger doses. It is not justifiable to give patients twice as much digitalis as they need as a matter of personal preference, especially since we do not know what other actions, harmful or otherwise, the drug may exert in the body.

DR. JOHN HENRY WYCKOFF, JR., New York: In reply to Dr. Wilson's query about patients who have congestive heart failure or have heart failure before they develop pneumonia, I think that such patients should be treated as any other patients with congestive heart failure; they should be given digitalis. Dr. Herold asked how patients might be rapidly digitalized if such was necessary when routine digitalis therapy was not used. In cases of sudden death in pneumonia it seems to me that it is doubtful whether digitalis medication would ever be of value; for example, such a condition as ventricular fibrillation. But when heart failure does occur, as in the presence of auricular fibrillation, digitalis is probably indicated. Such an effect can be obtained by giving it by mouth in six to eight hours, or in one or two hours by the intravenous use of ouabaine. As to the value of digitalis in preventing cardiac dilatation, if digitalis does prevent such dilatation it should have had that effect in patients treated in this series as digitalis medication was begun as soon as possible after admission.

THE DRINKER RESPIRATOR

ANALYSIS OF CASE REPORTS OF PATIENTS WITH RESPIRATORY FAILURE TREATED FROM OCTOBER, 1928, TO JUNE, 1930 *

NEW YORK

AND

DOUGLAS P. MURPHY, M.D.
Fellow in the Gynecean Hospital, Institute of Gynecologic Research, University of Pennsylvania
PHILADELPHIA

In a series of papers published in THE JOURNAL[1] and elsewhere[2] we have given a description of the construction, operation and application of an electrically driven device for the prolonged administration of artificial respiration. As the result of considerable experience in the use of the apparatus in certain hospitals in Boston, New York and Philadelphia, various technical improvements have been made and a small respirator has been developed especially for the initiation of respiration of babies who breathe either with difficulty or not at all at birth. Both types of respirator, in their latest form, are shown in the accompanying illustrations.

Essentially, the respirator consists of a sheet metal tank equipped with a comfortable bed and mattress. The patient's head protrudes through a flat soft rubber diaphragm or collar attached to the body of the respirator, the rubber collar making an air-tight seal about the patient's neck. The diameter of the collar is adjustable, and thus excessive tension on the neck of the patient is avoided.

By means of electrically driven blowers and an appropriate valve arrangement, the air pressure within the tank is changed alternately from a few centimeters negative pressure to normal atmospheric pressure. The negative pressure induces inspiration—the chest and diaphragm of the patient expand and air is inhaled. The return to atmospheric pressure allows the normal tone of the respiratory muscles to cause expiration. Both the size and the rate of breaths taken are under control of the attendant and can be measured (or recorded) by means of a suitable U-tube manometer, filled with colored water and connected by rubber tubing to the body of the respirator.

In general, negative pressure of about 12 to 18 cm. of water suffices to maintain adequate ventilation in an adult or child with complete respiratory paralysis. In the case of new-born babies in which respiration does not begin within a few minutes after birth, lower negative pressures (from 8 to 10 cm.) have been found adequate.[3] Our experience indicates that the negative pressure used should be sufficient merely to prevent cyanosis or obvious respiratory distress—nothing is gained by using excessive negative pressures for long periods, while we have reason to believe that such pressures actually do harm to the lung tissue, particularly in the case of infants whose lungs may be atelectatic.[4]

Without having the pump stopped, the patients can eat, drink and sleep while in the respirator. A bed pan can be passed through one of the port-holes, enemas can be given, and rectal drips can be administered in deglutition cases. The noise of the machinery, although not excessive, is sufficient to prevent the use of a stethoscope in chest and heart examinations. We have taken roentgenograms of patients' chests both while the respirator was running and when the bed was pulled out and the pump stopped.

ANALYSIS OF CASE REPORTS

At this writing, June, 1930, twelve adult-sized respirators are in use in New York hospitals and two in Boston hospitals. One child's and three infant's respirators are in the Children's and Lying-In hospitals in Boston and two infant's respirators are in use in the University and Lying-In hospitals in Philadelphia. In all, approximately forty adult patients have been treated in New York; six adults, six children and about twenty-five infants (full-term and premature) in Boston, and three infants in Philadelphia. As the result of the simplification of the apparatus, treatment in the respirator has become more or less routine hospital procedure and does not require specialized attention on our part. It has therefore become increasingly difficult to obtain complete records of all cases treated. Our analysis consists of a brief summary of cases in which we have complete information and which we believe to be of interest to the medical profession.

Acute Anterior Poliomyelitis: Of seven desperate cases of respiratory failure treated, four have been described in THE JOURNAL.[1] Of the final recovery of one of these, B. H.,[1] Dr. Frank R. Ober, consulting orthopedic surgeon to the Peter Bent Brigham Hospital, Boston, May 24, 1930, writes:

> It is impossible to say about B. H.'s ultimate recovery. When I first saw him on Sept. 26, *1929* [thirteen days after admission to the Peter Bent Brigham Hospital] he had a paralysis of practically every one of his skeletal muscles including the

muscles of his neck, back, thorax and abdomen, but not complete. His worst lesion was thoracic and abdominal. Associated with this paralysis he had marked tenderness of the lower extremities due to the peripheral neuritis which is so often associated with poliomyelitis. His chest expansion was less than one-half inch. October 3, his chest expansion was three-fourths inch and on October 10 it was 1⅛ inches. October 17, he was removed from the tank and his chest expansion dropped back to three-fourths inch. The tenderness in his leg muscles persisted until December 21, when physical therapy was started. He developed mild adduction contractures of both shoulders from exquisite tenderness and from the position in the tank. October 24, we put him back in the tank for short periods with the idea that the tank would relieve the fatigue of the chest muscles.

Today the contractures of his shoulders are about two-thirds eliminated and the power in the shoulder muscles is increasing. The power in his leg muscles has increased sufficiently so that he is able to walk about the house without any brace. His trunk muscles are still very poor, which interferes with his balance in walking. His chest expansion is now 2 inches. Crutches were necessary for some time but he no longer needs them except that he uses one to go up and down stairs, and he ought to be able to discard that.

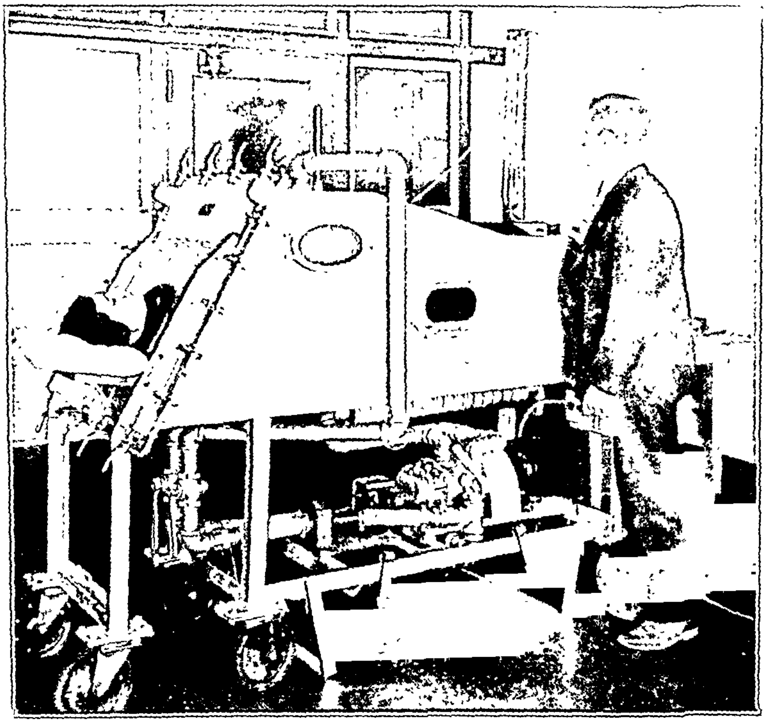

Fig. 1.—Adult-size respirator, showing rubber collar about patient's neck. The attendant is observing on the manometer the pressure within the respirator.

This boy has made a very marked and definite improvement since I first saw him in September. He has had daily physical therapy and only a slight amount of walking in the past few weeks and has had almost constant rest since he was first seen. He ought to gain constantly for an indefinite period. As to complete muscular recovery, I do not know, but functional recovery ought to be nearly normal.

A second case of poliomyelitis, in E. B., a boy, aged 10, has not yet been reported in the literature. Dr. Kenneth D. Blackfan of the Children's Hospital, Boston, and professor of pediatrics, Harvard University Medical School, under date of June 13, 1930, has written us about this child as follows:

I believe you should have the history of E. B., a boy of 9 years [on admission], who was treated in your respiration machine during the acute stage of infantile paralysis.

This boy was in good health until Sept. 16, 1929, when he complained of headache and stiff neck. He went to school but came home almost immediately and went to bed. He was feverish, irritable and nervous. That night he complained of pain in his back and he slept poorly. His condition remained about the same the next day. The third day a physician was called to see him. The diagnosis made at that time was infantile paralysis, established by the history, and paralysis of the left arm. September 19, the paralysis had spread to involve both arms and the intercostal muscles.

The child was seen at 2:30 a. m. by Dr. Aycock of the Harvard Infantile Paralysis Commission, who reported that the patient was "prostrated; flushed; restless; tremor. Rigidity of neck and spine; neck retracted; marked paralysis of both arms, paralysis of intercostal muscles; temperature 99.6 F.; pulse 138. Lumbar puncture: Pressure 200 mm. 'ground glass' appearance; cell count 112." Dr. Aycock obtained an ambulance and took the child and his father to the Children's Hospital (about seven hours' drive).

On admission, the boy's respirations were rapid and diaphragmatic in character. The chest did not move at all with inspiration. By this time the extremities had also become involved. He was removed to the respiration room, where he stayed for sixteen days. Throughout this time he was placed periodically in the respiration machine, spending about half the time in the machine during the first week and about one third of the time in it the second week.

While this boy at the time of admission was not in urgent need of artificial respiration, the effect of the assistance rendered by the machine was considered most beneficial as indicated (1) by the fact that the boy slept hardly at all outside the machine but would fall into a deep sleep as if exhausted when the assistance of the machine was given him; (2) the anxious attitude which he manifested when outside the machine was replaced by a sense of security; (3) the respirations were rapid, from 40 to 50, outside the machine, but were very much slower inside; lastly, and most important, after the first experience in the machine the boy periodically asked to be put in.

In the treatment of this child, negative pressure only was used, most of the time at — 14 centimeters. The pressure was run to — 30 occasionally, which disturbed the boy the first time it was done, but later he desired it this way when first put in the machine. The rate of artificial respiration was 35 the first day and from 25 to 30 thereafter.

Gradually his muscles returned so that it was no longer necessary for him to be kept in the tank and after the sixteenth day he was removed to the ward. Subsequently he was transferred to the orthopedic service, where treatment in the respiratory tank was continued in order to increase the chest expansion, and thus, if possible, to protect him somewhat against congestive, respiratory infections.

The subsequent course of the child has been given us by Dr. Arthur T. Legg, of the Children's Hospital, Boston, and Harvard Infantile Paralysis Commission, June 11, as follows:

When he was transferred to the orthopedic service E. B. had but one-half inch chest expansion. He was placed in the respirator periodically to rest the involved muscles and in the hopes that the action of the machine would develop chest expansion. At present he is able voluntarily to expand his chest 2¾ inches. He has not had any sign of a cold.

Four weeks ago I started another patient in the respirator. His paralysis began in 1927 and he had marked intercostal involvement. He has had many colds since that time and pneumonia on two occasions. He had an expansion of half an inch a month ago, since which time we have had him in the respirator twice a day (for a month). He now has a voluntary expansion of 1½ inches.

I believe the machine is going to be a wonderful asset in the after-treatment of intercostal muscles following infantile paralysis.

Our failures so far indicate that in bulbar involvement the respirator is apt to be ineffective. Also we have found that it is of the utmost importance occasionally but regularly to change the patient's position in order to prevent pulmonary congestion. For adults this means the development of a team, preferably of men, who call at scheduled times and do the necessary lifting and moving of the patient. At other times, a nurse in constant attendance has been found to be essential.

In general, it appears that respiratory failure in acute poliomyelitis is relieved and cyanosis is prevented. Whether or not a patient acutely ill will recover as the result of the respirator's having tided him over the most critical part of the illness is unpredictable.

Gas Poisoning (carbon monoxide).—In the emergency ward of the Bellevue Hospital, New York, the respirator is used two to three times each month (thirty-one cases since May, 1929). Of the forty cases in New York, seventeen have been gas poisoning (carbon monoxide). Nine of the patients recovered and were discharged from the hospital. In every instance inhalations of 95 per cent oxygen and 5 per cent carbon dioxide or 93 per cent oxygen and 7 per cent carbon dioxide were used before placing the patients in the respirator. Generally (and always in the emergency ward of the Bellevue Hospital), the oxygen and carbon dioxide mixture is used with the respirator when the patient is unconscious or when there is any evidence that the gas mixture is beneficial.

Most of the carbon monoxide cases are the result of attempted suicide, generally complicated by serious ill health. They are not typical "gas poisoning" cases. The usual type of accidental carbon monoxide poisoning can be treated fully as well by the oxygen and carbon dioxide inhalation method alone as by the respirator.

Alcoholic Coma.—Eight patients, seven in New York and one in Boston, were diagnosed as suffering from alcoholic coma and placed in the respirator when other resuscitative measures had proved inadequate. In two cases, this diagnosis was complicated by the presence of drugs, and in one by carbon monoxide as well, and in another by a fractured skull. Of the eight patients treated, three recovered.

Drug Poisoning (morphine, heroin, barbital).—In New York, five patients with drug poisoning were treated in the respirator in the Bellevue Hospital. Of these, three recovered and one regained consciousness but died two days later. Of the three who recovered, the first had been reported in The Journal.[5]

Drowning.—One patient, a man, aged 45, was treated in the Bellevue Hospital. He recovered and was discharged.

Postoperative Respiratory Failure.—A woman, aged 22, was operated on for scoliosis. She had had poliomyelitis when a child, recovered, but grew up markedly deformed and with inadequate upper respiratory muscular control. At the time of her operation her normal respiratory rate was about 30; she was examined carefully and thought to be a good surgical risk. The operation (Hibbs') lasted approximately one and one-half hours. For the next two or three days she was anxious and apprehensive, with some cyanosis. On the eleventh day she became badly cyanosed and was unconscious when placed in the respirator. She regained consciousness quickly and then fell into a deep sleep. Because her heart was weak, pulse rapid and breathing dyspneic she was treated in the respirator constantly for ten days and at night for about one month; then she took naps in it twice daily for several weeks more. After two months she was taken home, although the condition of her heart was unsatisfactory. She died suddenly about three months after her operation. In this particular case it was apparent that the respirator always relieved cyanosis and caused a fall in pulse rate. When she was placed in the machine, her pulse rate would be about 140 and would gradually drop to about 120. So far this is the only case we have had in which the respirator apparently had a direct effect on the heart action.

Asphyxiation of the New-Born.—We are in entire agreement with the conclusions reached by Wachenfeldt[6] in the treatment of the axphyxiated new-born and particularly of premature infants, as shown in his recent discussion of the use of Thunberg's modified baby barospirator; namely, that there is a field for the device in the treatment of new-born babies in whom respiration is not initiated by the usual means.

Murphy and Coyne[3] have shown that natural respiration may be entirely absent for as long as one hour and eight minutes and only partially restored at the end of two hours and seventeen minutes, during all of which time the baby was kept alive in the respirator. At the end of the two hour treatment the baby gradually resumed normal breathing and the respirator was stopped. The same investigators have shown also, and with this Wachenfeldt seems in agreement, that artificial respiration in atelectatic premature infants is extremely difficult. Whether the respirator has application in this problem we are in doubt, but it is hoped that cases of premature infants that have been treated will be reported later. Of such cases there are now a considerable number, but we cannot, at present, give the details.

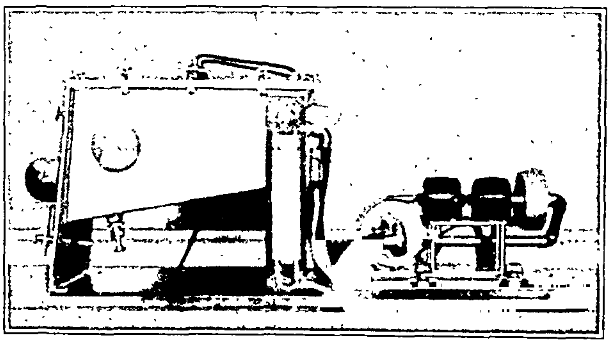

Fig. 2.—Baby-size respirator containing doll. The head end is hinged so that the angle of inclination of the baby may be adjusted; two 40-watt lamps are attached inside to furnish light and heat. Pump and valve are shown on the right.

We are indebted to Dr. Stewart H. Clifford, assistant visiting pediatrician to the Boston Lying-In Hospital, for the following account of the action of the respirator on a new-born baby:

> A baby was born, severely asphyxiated, at the Boston Lying-In Hospital, May 26, 1930. The family history was unimportant. The mother was at full term and delivery had progressed in a normal fashion until the fetal pulse fell from 120 to 40 beats per minute. In order to save the baby the membranes were ruptured, an episiotomy was performed, and the baby was delivered without difficulty by pressure on the fundus.

[6] Von Wachenfeldt, S.: Von der Wiederbelebung [illegible] scheintoter Kinder Versuche mit Thunberg's Barospirator (On the Resuscitation of New Born, Apparently Dead, Children: Experiments with Thunberg's Barospirator), Acta [illegible] et gynec. [illegible] 1930.

At birth the baby was intensely cyanotic and the usual methods of resuscitation failed to stimulate respiration. After three or four minutes the baby was thought to be beyond hope but was placed in the respirator. The baby had not so much as gasped but as soon as the respirator was started the cyanotic color disappeared, and after three minutes the baby gave one gasp. The respirator was kept in operation for one and a half hours with the baby gasping every one to three minutes before he was able to maintain his own respiration. When the machine was stopped the respirations continued to be shallow and rapid. During the next eight hours the respirations ceased twice and the baby became intensely cyanotic, necessitating the use of the respirator.

Twelve hours after birth the baby was transferred from the respirator and lived for four days. During this time there were frequent cyanotic attacks and convulsions with breathing of the Cheyne-Stokes type. Lumbar, subdural and ventricle punctures showed normal fluid. Over the skin there were numerous petechiae but the rest of the physical examination was negative.

On the fourth day pneumonia developed, and the next day the baby died.

There was a postmortem which confirmed the clinical diagnosis of intra-uterine asphyxia with petechial hemorrhage into the various organs including the respiratory center.

Obviously this particular infant had no chance to live and I send you this note merely to show the action of the respirator on an asphyxiated infant.

COMMENT

We have often been asked: "What are the contraindications for the use of the respirator?" or, again, "Can it do harm?" We believe that contraindications are simply those of observing the patient's reaction to the respirator. If the patient is not suffering from respiratory difficulty or is not cyanosed, there is generally no point in using the respirator. If the patient does not respond to the treatment and does not spontaneously breathe in synchronism with the machine, the artificial respiration may actually interfere with his voluntary breathing and certainly does no good. Even in the case of conscious patients who are frightened and apprehensive but badly cyanosed, we have experienced no great difficulty in putting them into the respirator. A patient can be transferred from a bed or stretcher to the respirator very easily in less than one minute by inexperienced persons.

In many instances morphine has been given to patients who are already in respiratory difficulty but are apprehensive of the machine and are restless. This treatment has proved effective, especially in poliomyelitis, but obviously it is to be used only when the respirator is immediately available or when the patient has already been placed in it.

In the treatment of infants who do not respond to the customary respiratory stimuli at birth, the respirator seems particularly applicable. In such instances the machine must be near at hand, preferably in the delivery room or a room adjoining. A sufficient number of patients have been treated to indicate that, for the newborn, the respirator has a very useful field.

ABSTRACT OF DISCUSSION

Dr. Reginald Fitz, Boston: One of the most dreaded complications of acute poliomyelitis has been respiratory paralysis. One patient whom I saw would certainly have died had it not been for Dr. Drinker's machine. A young man with respiratory failure from infantile paralysis entered the hospital. He was at once put in the respirator. He soon was able to describe the benefit he received by it. When he was first taken out of it, he became apneic. Gradually he grew better and after living in the machine for a few weeks was able to be out of it for a few minutes at a time without discomfort. Now he is perfectly all right as far as his respiration is concerned. I believe that this machine is going to have considerable clinical importance in the future, especially in any general hospital that is likely to have an accident room service, for it is in the accident room that emergency cases will enter with various types of inability to breathe. Certainly, in acute poisoning cases in which there is respiratory failure the machine ought to be of distinct practical value, for in these it is largely a question of tiding the patients over a comparatively short time before recovery occurs. If there are to be epidemics of infantile paralysis in the future, hospitals treating such cases should be equipped with the respirator. One life saved is worth a lot, and it is comforting, at least, to have something in the line of rational therapy to offer those cases of respiratory failure which heretofore were doomed. I was rather doubtful about the machine at first. It looked cumbersome, it was noisy, and it seemed more like a torture chamber than anything else, but certainly the one boy that I saw get well in it entirely convinced me as to the practical value of this method of giving artificial respiration.

Dr. W. Lloyd Aycock, Boston: From the point of view of the ultimate outcome of the disease, paralysis may be divided into two kinds: Permanent paralysis, certainly due to the destruction of the motor cells in the spinal cord, and temporary paralysis, undoubtedly due to a temporary interference with nerve cells which are not actually destroyed. Temporary paralysis is seen in all parts of the body. Every patient with infantile paralysis who survives undergoes improvement to a greater or less extent in the actual amount of paralysis. One of the most striking examples of temporary paralysis is seen in a type of case which is becoming more frequent; namely, paralysis of the swallowing mechanism. Many of these patients are completely unable to swallow for four or five days, after which they recover entirely. When temporary paralysis involves a group of muscles that are not absolutely essential to life, there is no danger to the patient. A patient can live five days without swallowing. But when the paralysis involves a vital group of muscles, such as the muscles of respiration, the patient cannot survive cessation of the use of these muscles for any length of time. As a matter of fact, when the intercosal muscles and the diaphragm become paralyzed, these patients undertake to give themselves artificial respiration by means, first, of their neck and shoulder muscles, and then the muscles of the mouth. Of course, they cannot keep this up for any length of time. Many devices have been tried for aiding the patient with this artificial respiration. None have ever been successful, owing, primarily, to the violation of the principles of respiration, and, secondly, to the fact that one is dealing with a perfectly conscious patient who realizes his breathing difficulty and who will not permit any muzzling of his face when he is in this condition. Early in Dr. Drinker's work on this machine, we were fully convinced that it might serve the desired purpose in infantile paralysis, and we have used it in several cases. We can't predict in any case whether there will be a return of function. None of the signs or symptoms give any indication of the ultimate extent or outcome of paralysis, so the best we can do is to give all these patients the benefit of the doubt. Some of them undoubtedly will resume their muscle power while others may not. It may seem like an emergency measure that cannot be made available to any extent, but with a few of these machines stationed at central points, it is not difficult to get a patient to the machine. I was called to Vermont last fall to see a suspected case back in the hills. I found this boy with a beginning intercostal paralysis. We got him to Boston, a matter of a seven hours' ride, and into this machine. He had been lying awake for many hours; as soon as the machine started he fell sound asleep. We stopped the machine and immediately he woke up. We started it again and he went back to sleep. We tried this several times. This boy has now made quite a remarkable recovery. The point is that in respiratory paralysis the patient has to use voluntary effort to keep up breathing. To one whose job it has been to sit by these gasping, moribund patients, to see them immediately take on the aspects of a perfectly well person when placed in the respirator is gratifying.

Dr. Millard Knowlton, Hartford, Conn.: I should like to ask Dr. Drinker the cost of the apparatus.

Dr. William R. Redden, New York: In 1927, a rescue squad which I had trained in Youngstown, Ohio, was called on to give artificial respiration to a victim of Landry's paralysis which had gradually involved the diaphragm. The men continued artificial respiration for about twenty-eight hours during which time the victim remained conscious. Eventually, as was to be expected, he died. The description members of the rescue squad gave me of the discomfort and even agony that this victim suffered from the application of artificial respiration by manual pressure made me realize that any type of apparatus such as Dr. Drinker has developed has marked value. In the case mentioned, and in similar cases, the Schaefer method of artificial respiration is out of the question because no conscious person can tolerate the amount of pressure used in this method for more than an hour, at least not without great shock. For this reason, none of the usual forms of artificial respiration are used, but the victim is placed on his back in a comfortable position on a table or bed, and then manual pressure is applied simultaneously at the anterior costal margin by two operators, one standing on each side. Even this greatly modified manual pressure method soon becomes almost unbearable for the conscious victim. Therefore, any type of respiratory failure which may require prolonged artificial respiration, but especially those in which the victim remains conscious, should be treated as soon as possible in a machine like Dr. Drinker's, which does no damage to the victim, which causes no pain or distress, and which even allows the victim to sleep. Aside from its use in respiratory failure, let me suggest that sleepless patients, instead of being given drugs, be put in this machine and the blood overoxygenated, and I am sure they will drop off to sleep without trouble.

Philip Drinker, Ph.D., Boston: Answering Dr. Knowlton's question about cost, the adult size machines are sold for $2,000. Dr. Redden mentioned Landry's paralysis. Recently I was called in an emergency to the Boston City Hospital and used the respirator in a case of Landry's disease. All we accomplished was to make the woman comfortable; she died gradually. I understand that in Landry's paralysis recovery is unknown. I did not mention that we know the apparatus can do harm under certain conditions. This we found through animal experimentation and not on patients. We curarized animals and then subjected them to more pressure than was necessary merely to sustain life. If the animal lay tilted head downward we found we could use higher negative pressures than if the animal lay horizontally. As a result, we have arranged the baby respirator so that excessive pressures cannot be obtained and do not let the baby machines go to hospitals until the danger from using excessive pressures is understood. In animals examined post mortem the damage, if any, is grossly apparent in the dependent portions of the lungs. Patients remaining in the respirator for twelve hours or longer require a trained crew who can either take them out, turn them over and put them back in the machine again, or else, if the space within the machine permits, put in side boards by the patient's side and tilt him first to one side and then to the other, just as one would in postoperative recoveries.

Medicine and Science.—The practice of medicine in its broadest sense includes the whole relationship of the physician with his patient. It is an art, based to an increasing extent on the medical sciences, but comprising much that still remains outside the realm of any science. The art of medicine and the science of medicine are not antagonistic but supplementary to each other. There is no more contradiction between the science of medicine and the art of medicine than between the science of aeronautics and the art of flying. Good practice presupposes an understanding of the sciences which contribute to the structure of modern medicine, but it is obvious that sound professional training should include a much broader equipment.—Peabody, F. W.: Doctor and Patient, New York, Macmillan Company, 1930.

LYMPHATIC LEUKEMIA

WITH GENERALIZED FOLLICULAR ERUPTION OF TUBERCULOMATOUS ARCHITECTURE *

GEORGE J. BUSMAN, M.D.
AND
ARTHUR R. WOODBURNE, M.D.
PITTSBURGH

An extensive literature has accumulated on the classification and interpretation of diseases of lymphatic origin. Cutaneous reactions occur in both general types of leukemia but are notably more common in the lymphatic variety.

Cutaneous and subcutaneous changes are occasionally noted at some time during the course of many diseases of the hematopoietic system. This is especially true in that closely allied group of diseases designated by Keim[1] as the lymphoblastomas, including leukemia, mycosis fungoides, lymphosarcoma and Hodgkin's disease. Arndt,[2] in 1914, classified the visible expressions of the leukemias in two classes: first, the diffuse or circumscribed true lymphadenoses and, second, a multiform type of lesion which did not represent a true leukemic infiltration and which was indistinguishable from the toxic dermatoses of different origin. The latter were designated as the leukamids. It is concerning this class that much further elucidation is needed. The following case is reported for the reason that the unusual relationship of a blood picture of a

chronic low grade lymphatic leukemia and a papular eruption of tuberculomatous structure may add something to clarify this picture.

REPORT OF CASE

History.—J. M., a white woman, aged 53, American born, a housewife, had had the usual diseases of childhood and typhoid at 20; otherwise her personal history was unimportant. Her mother and father had both died, but the cause was not elicited. Three brothers were living and well. She had no sisters. There was no history of tuberculosis, cancer, nephritis, syphilis or insanity.

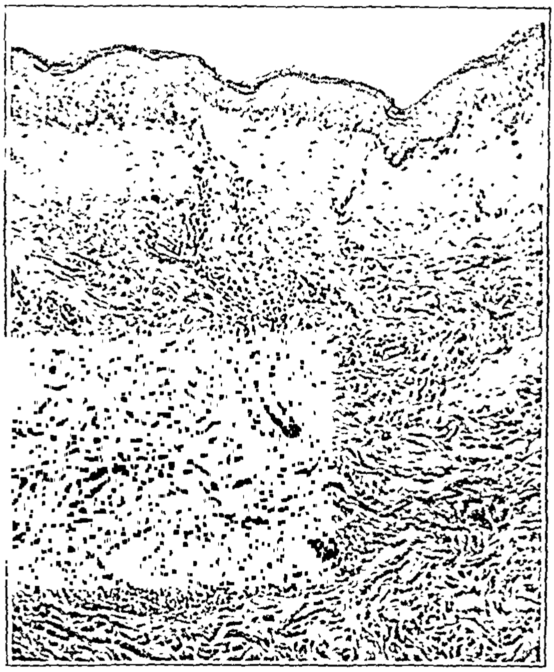

Fig. 2.—Infiltrate about the sweat duct and vessels and early formation of epithelioid cells in the lower cutis; × 100.

Present Illness.—The present illness began in the spring of 1926. It began as a slight follicular papular eruption on the trunk. The patient did not consult her physician regarding it until June, 1928, at which time she also suffered with backache. Laboratory tests at that time revealed a negative blood Wassermann test and a negative urinalysis. Blood examination revealed hemoglobin, 98 per cent; red blood cells, 4,930,000 and white blood cells, 20,900 per cubic millimeter. The differential count showed; polymorphonuclear leukocytes, 22.5 per cent; lymphocytes, 77.25 per cent, and basophils, 0.25 per cent. Roentgenograms of the lumbar and sacro-iliac regions showed no evidence of abnormality in the bones of the lower dorsal or lumbar region. The joint margins of the sacro-iliac joints showed an increase in bone density suggestive of bone sclerosis, which might lead one to believe that there existed a chronic arthritis involving the sacro-iliac joints. Dental roentgenograms were made of all teeth, and three periapical abscesses were revealed. These teeth were promptly extracted and the abscesses removed by curettement, July 31, 1928, she was referred to us by David M. Bell, M.D., of Canonsburg, Pa.

Cutaneous Examination.—The entire skin surface of the trunk, arms and legs was covered with a fine follicular papular eruption (fig. 1). The individual lesion was a very small keratotic papule, capped with a small horny spine which could be removed only with considerable difficulty. Each papule was surrounded by a small margin of erythema. Over the arms, legs, upper back and neck, the lesions were all distinctly discrete. On these areas, the lesions resembled very much the characteristic papules of keratosis pilaris. The papules were more closely studded and more abundant on the flexor surface of the extremities rather than over the extensor (keratosis pilaris) surface. On the lower part of the trunk (around the back and abdomen) the spines appeared to have been rubbed off. The papules were larger and flatter, and there appeared more of a tendency to but no actual confluence of lesions. Also here they were yellower or more apple jelly-like in quality. The face, palms, soles and the dorsal surfaces of the fingers and toes were free from lesions. There was no caputal, pubic or axillary alopecia. The condition was only mildly pruritic and there was no thickening or excoriation or trauma due to excessive scratching.

Physical Examination.—The patient was of medium height, weighed 135 pounds (61.4 Kg.) and was well nourished. The eyes, ears, nose and mouth were normal. The thyroid gland was not enlarged. There was a single, discrete, palpably enlarged gland in the left anterior cervical chain. Other glands were not enlarged. Her heart and lungs were normal except for a mild atherosclerosis not unusual in patients of her age. Her liver was palpable at the costal margin. The spleen was enlarged to percussion only. Laboratory study showed a basal metabolic rate increased 9 per cent; urinalysis was normal; the phenolsulphonphthalein excretion was 39 per cent in two hours; the nonprotein nitrogen was 31.5 mg. per hundred cubic centimeters; urea nitrogen, 11.5 and blood sugar 97. Blood examination showed: hemoglobin, 80 per cent; erythrocytes, 5,650,000 per cubic millimeter; white blood cells, 24,400. The differential count was: polymorphonuclear neutrophils, 12 per cent; eosinophils, 1 per cent; small lymphocytes, 83 per cent; large lymphocytes, 3 per cent, and transitionals, 1 per cent. Many cells were embryonic in type.

The diagnosis of a consultant internist was that of "typical chronic low grade leukemia." The patient was presented before the Pittsburgh Dermatological Society, and Hollander[3] voiced the opinion of those present that it was a most unusual and interesting case. A section of skin containing many typical papules was removed for study.

Pathologic Examination.—The following report was submitted by Dr. H. H. Permar, pathologist of the Mercy Hospital:

Macroscopic History: The specimen was of a small elliptic piece of skin from the chest, measuring 1 by 0.5 cm. and having a thickness of 0.5 cm. The material was received after fixation, and in that state it failed to show the small superficial lesions noted in the clinical history.

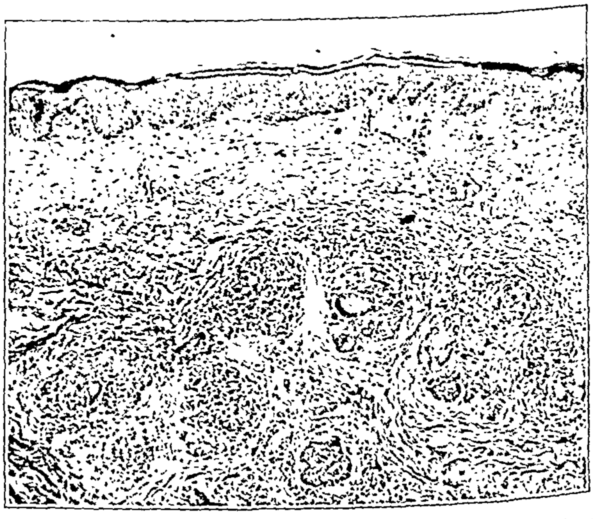

Fig. 3.—Typical tuberculoid structure. The tubercle at the left shows early central caseation. A hair follicle is shown in the lower center; × 100.

Microscopic History: Sections of the skin showed foci of chronic inflammation which were clearly granulomatous in type (fig. 2). They lay in the corium and tended to be fairly close to the epidermis. (In one place the papillae of the malpighian layer were distinctly flattened over the inflammatory area, and the epidermis was thin with some increase in the amount of keratin [figs. 3, 4 and 5].) This probably represented one of the small keratotic papular lesions.

---

[3] 3. Hollander, Lester: Transactions of the Pittsburgh Dermatological Society, Arch. Dermat. & Syph. 19: 326 (Feb.) 1929.

The granuloma had the classic histologic picture of miliary, submiliary and early conglomerate tuberculosis. The inflammatory nodules were made up of flattened or ovoid epithelioid cells having an irregularly concentric arrangement about small centers of early caseation necrosis (fig. 6). Typical Langhans giant cells were located eccentrically in the nodular foci and were not seen in every one. The larger foci showed a few polymorphonuclear leukocytes lying in the areas of early caseation necrosis. Zones of lymphocytes encircled the rounded masses of epithelioid cells, and just beyond these the nodules were demarcated by a zone of fibrous tissue. The vessels of the corium showed collections of lymphocytes and plasma cells lying in the perivascular lymphatics and in the stroma about them; and the sweat glands were surrounded by similar cell collections, again evidently in lymphatics (figs. 7 and 8). An occasional small lesion, perfectly characteristic of a miliary tubercle, was found along the course of the lymphatics in the corium, often at some distance from the larger foci.

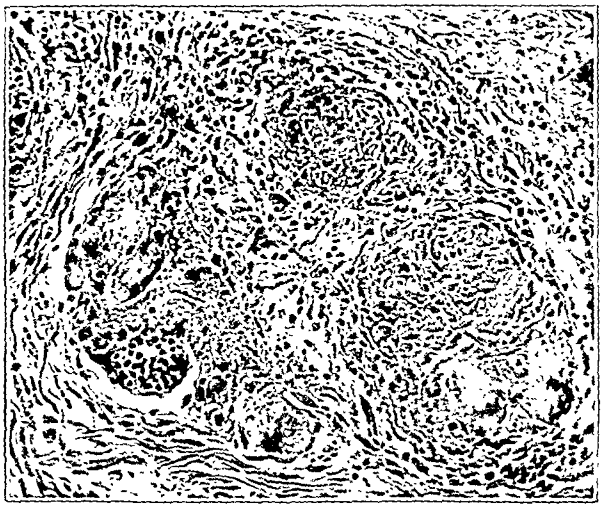

Fig. 4.—A portion of figure 3. Note lymphatic or blood vessel in lower left hand corner which is packed with immature white blood cells; × 225.

The diagnosis was tuberculosis of the skin of the chest.

Treatment, Clinical Notes and Progress.—Although we were unable to demonstrate whether the pathologic blood picture was the primary disease and the skin expression secondary or vice versa, we felt as the internist and hematologist did that we were dealing with a leukemic syndrome. From her first visit, July 31, to Aug. 27, 1928, only internal tonic medication and local soothing applications were administered.

She was then given four one-half skin unit roentgen-ray exposures, one half of the body surface being irradiated weekly such that the total consisted of one skin unit to the entire body surface. Following this treatment there was an initial rapid fall in the white blood count. The differential count also showed a rise in polymorphonuclear leukocytes and a fall in lymphocytes. At the time the smear also showed many degenerating white blood cells, largely of the lymphocytic type. There was likewise a corresponding resolution in skin lesions and less itching.

September 27, intramuscular injections of spleen extract were begun. These were continued for a total of twenty-four semiweekly, weekly or biweekly injections. During this period the patient's blood picture gradually became normal, as shown in the accompanying table.

COMMENT; DIFFERENTIAL DIAGNOSIS

Cutaneous and subcutaneous changes have been so frequently reported in connection with the lymphoblastomas that we consider it needless here to enter into a complete discussion of these various cutaneous expressions in the form of leukamids and true leukemic infiltrations so ably described by Arndt, Keim and others.

In no case that we have reviewed has there been described a skin lesion associated with a leukemic blood picture which showed the clinical or histopathologic architecture of our case. The blood picture is definitely that of a chronic lymphatic leukemia. This point of view was substantiated by Dr. George Kastlin, hematologist at the Mercy Hospital. The histologic picture is not that of a true leukemic infiltration of the skin. The pathologic changes in the circumscribed type consist of a dense infiltrate of small or large lymphocytes, located principally around the blood vessels, the follicles and glands. There is an edematous zone of noninfiltrated tissues between the reticular layer and the epidermis; a very little increase in connective tissue, and a loss of elastic tissue and pilosebaceous structures in the larger tumors. In the diffuse type of leukemia cutis, the pathologic changes are quite similar except that the infiltrative process is general. The leukamids are associated with but do not present a histologic picture of a true leukemia. They are supposedly the result of an intoxication from the underlying leukemia and show themselves as petechiae, papules, vesicles, wheals, nodules, pigmentation, exfoliation or a simple general pruritus. In no instance have we found a description of a leukamid as a spine capped papule with a histologic picture of tuberculosis.

Gans [4] describes the leukamids as nonspecific reactions in myelosis and lymphadenosis. He says, "The nonspecific variety bears but loose relationship to the underlying disease and needs further elucidation."

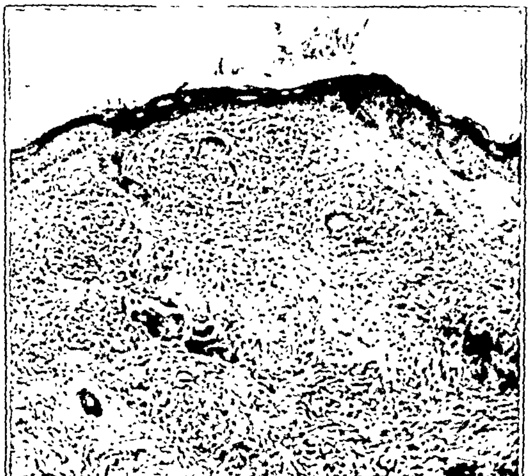

Fig. 5.—Taken where the epidermis was flattened and it showed several tubercles, one near the hair follicle. × 75.

It is of interest here to refer to the study of Michelson [5] on the occurrence of tuberculoid reactions in the inguinal glands in early syphilis. Of twenty-nine cases of early syphilis in which the inguinal glands were examined, tuberculoid reactions were observed in eight. Two types of tuberculoid reactions were noted, the so-called epithelioid or indurative tuberculoid structure involving almost the entire node, and a second type likened to that found in miliary tuberculosis.

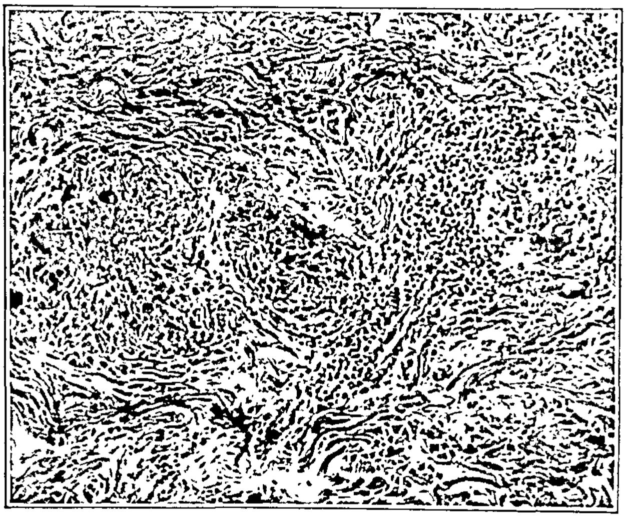

Fig. 6.—On the left, tubercle with early central caseation necrosis; epithelioid cells about the blood vessel in center, and a perivascular infiltrate of cells of the lymphocytic series, extending diagonally across the right side; × 150.

Professor Bloch [6] in discussing this report, stated that this structure was not specific for a tuberculous infection but that it could be found in many diseases, such as in leprosy, tertiary syphilis, sporotrichosis, trichophytosis and blastomycosis. He says, "The rule that tuberculous structures are found not only in tuberculosis but in many other infections, when allergic conditions are present, is not sufficiently known and considered by pathologists."

Clinically the lesions are rather suggestive of a generalized lichen scrofulosorum. The papules were follicular and capped by a horny spine. Around the lower trunk there was some tendency to flattening. The lesions were yellowish and waxy in color and covered by minute scales. On the other hand, there was no tendency whatever to grouping. Also the eruption was almost uniformly distributed over the entire trunk and extremities. The age of the patient was somewhat over the usual age incidence of lichen scrofulosorum. Careful clinical and roentgen examination failed to reveal any evidence of active or healed tuberculosis.

Histologically, the sections showed numerous giant cells and caseation necrosis. Pusey [7] states that "most observers have demonstrated the presence of giant cells, but other elements of the typical tuberculous process, such as coagulation necrosis and caseation, have not been observed in lichen scrofulosorum." Wise [8] and Michelson [9] reported that small areas of caseation occurred in some cases but that ordinary inflammatory changes are found more frequently than the tuberculoid structure. Plasma cells are rare.

Towle and Swartz,[10] in studying the blood count in tuberculosis of the skin in twenty-five cases, report the total white count ranging from 7,000 to 15,000. The average normal was 10,360. The polymorphonuclears ran as low as 1,320 and as high as 10,530. The average was 6,392. The highest lymphocyte count was 8,760, the lowest 4,000, with an average of 3,299. Mononuclears were low, with a total average of less than 300. These figures seemed to agree with the figures in internal tuberculosis.

Pityriasis rubra pilaris must be considered in the differential diagnosis of a general follicular papular dermatosis of this type. In our case there were no lesions of the proximal phalanges, nor was there any alopecia. The lesions were discrete, with no tendency to coalescence at the end of two years' duration. The true tubercular histopathology and blood picture also do not fit in with this condition.

The blood picture of a chronic lymphatic leukemia and the tuberculomatous architecture of the skin lesions differentiate it from such conditions as lichen planus, lichen nitidus, lichen spinulosus, follicular syphilids, trichophytids and other follicular papular dermatoses.

The case is unique in that it showed the blood picture of a chronic lymphatic leukemia associated with a follicular papular cutaneous eruption with a true tuberculomatous structure. We are unable to demonstrate positively which one of the two pictures was primary. The case can be argued as one of a chronic lymphatic leukemia and the skin picture as a leukamid. Although the leukamids are supposedly toxic or allergic expressions of the underlying blood dystrophy, little is known of the actual histopathology of these lesions. In view of Michelson's observations in syphilis and Bloch's reference to tuberculoid reactions to allergy, it is logical to presume that the tuberculomatous structure of the cutaneous lesions in our case is an expression of an allergic nature.

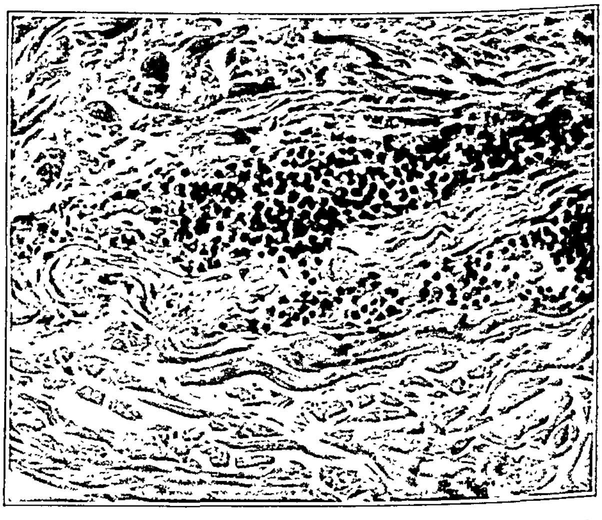

Fig. 7.—Character of the infiltrate about the arrectores pilorum muscle; × 300.

Considering the existence of a mild lymphocytic leukocytosis in cutaneous tubercular structures, one must analyze the condition as a tubercular skin eruption, possibly generalized lichen scrofulosorum. The histopathologic architecture in which there is tubercle formation with giant cells and coagulation and caseation necrosis, so dominant a feature, is not that of the usually accepted pathology of lichen scrofulosorum. The abnormally high leukocyte count is out of proportion to blood counts reported in association with cutaneous tuberculosis. Also, the age of the patient, the absence of grouping, and the lack of any collateral evidence of tuberculosis argues against the skin picture as being the primary feature in this case. The associated blood and clinical picture reasonably excludes the other follicular papular cutaneous possibilities.

Regarding the almost miraculous response to treatment we are unable to conclude whether the entire course of progress was the result of the roentgen treatments or of the subsequent injections of spleen extract. The use of spleen extract in allergic dermatoses was first reported by Leo von Zumbrusch[11] of Munich. Having observed that splenectomized animals and eczematous patients both have eosinophilia, and that roentgen stimulation of the spleen resulted in improvement of eczematous lesions, an albumin free extract of hog spleen was administered with astonishing results to patients with eczematous lesions. Paul[12] reported striking results from the use of spleen extract in a series of cases of eczema, urticaria, pruritus ani, asthma, lichen planus, miliaria and psoriasis.

Beinhauer[13] obtained a rapid relief of pruritus and a sharp decrease in eosinophilia in a series of cases in which spleen extract was used. Although our case did not show an appreciable eosinophilia, the possible allergic tuberculomatous type of skin lesion associated with the blood picture of a hematopoietic disease led us to use spleen extract as a therapeutic agent.

SUMMARY

We report an unusual case with a generalized follicular papular eruption. The individual lesion was a discrete keratotic papule capped by a small horny spine and surrounded by a narrow erythematous margin. The histopathologic structure was that of miliary, submiliary and early conglomerate tuberculosis.

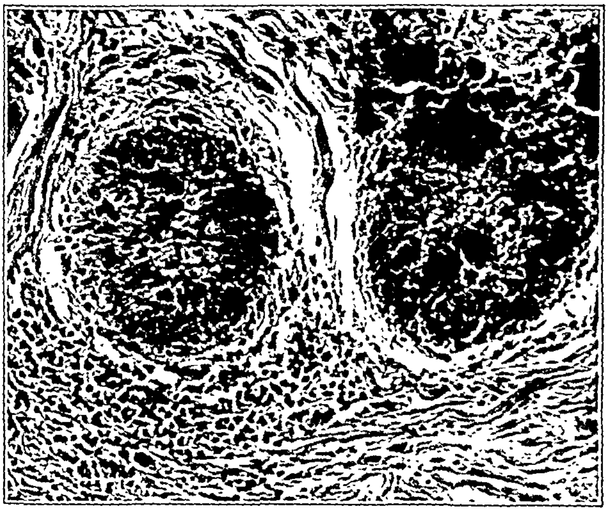

Fig. 8.—A poor photomicrograph which shows early central zone of caseation and peripheral zone of lymphocytes about one of the tubercles; × 250.

There was an associated blood picture of a typical chronic low grade leukemia. The blood showed: hemoglobin, 80 per cent; erythrocytes, 5,650,000; white blood cells, 24,400 per cubic millimeter. The differential count was: polymorphonuclear neutrophils, 12 per cent; eosinophils, 1 per cent; small lymphocytes, 83 per cent; large lymphocytes, 3 per cent, and transitionals, 1 per cent.

13. Beinhauer, L. G.: Personal communication to the authors.

After roentgen-ray exposure of one skin unit in divided doses to the entire skin surface, there was a rapid decrease in leukocytosis and improvement in the relative percentages of white blood cells.

During and after a total of twenty-four semiweekly, weekly, or biweekly injections of spleen extract, the cutaneous and blood pictures returned to normal and have remained so after eighteen months' observation.

Clinically the skin lesions were rather suggestive of a generalized lichen scrofulosorum. However, the absence of grouping, the age of the patient, the failure to demonstrate active or healed tuberculosis, the true tuberculous histopathologic architecture, and a lymphatic leukocytosis out of proportion to that of general and cutaneous tuberculosis in our opinion ruled out this diagnosis.

We cannot prove whether the blood picture was the primary pathologic change and the skin expression secondary, or vice versa. In view of the fact that tuberculous structures are found not only in tuberculosis but also in many other infections, when allergic conditions are present, we believe that this case is one of a chronic, low grade, lymphatic leukemia in which the cutaneous eruption is that of a leukamid with a definite tuberculomatous architecture.

515 Grant Street.

ABSTRACT OF DISCUSSION

Dr. Hamilton Montgomery, Rochester, Minn.: Transitions between all the various forms of lymphoblastoma can occur. Many cases of lymphatic leukemia, however, remain typically such throughout the course of the disease. The skin manifestations of lymphatic leukemia may be divided into two groups: (1) true leukemic infiltrations of the skin (leukemia cutis) and (2) toxic reactions (leukamids). The authors' case presents certain features of extraordinary interest not only from the clinical but also from the pathologic point of view. The histopathologic features are open to various interpretations concerning which there probably would not be a uniformity of agreement between different pathologists. I believe the case represents a true leukemia cutis in which a tuberculoid reaction is occurring. Sections of the skin revealed numerous tuberculoid nodules, many of them centered about a blood vessel, simulating the microscopic picture of a sarcoid or a tuberculosis cutis indurativa. In several areas, however, the adjacent lymph vessels were packed with lymphocytes and lymphoblasts. There was also a dense infiltrate of immature and mature lymphocytes about arrectores pilorum muscles and also about a sweat duct. This case, therefore, differs from the usual types of leukemia cutis. These may be divided into: (1) the discrete nodular type with or without ulceration; (2) the diffuse erythematous type (malignant erythroderma), and (3) those rare cases in which there are true leukemic infiltrations in and about the blood vessels in the skin with as yet no macroscopic or clinical evidence. I know of only one case of lymphatic leukemia in which a tuberculoid reaction occurred in the skin. Ramozzotti (*Giorn. ital.* **70**:1283, 1929; abstr. *Zentralbl. f. Haut- u. Geschlechtskr.*, April 20, p. 374) describes a typical case of lymphatic leukemia in which there developed lesions which clinically and histologically were papulonecrotic tuberculids and in which the tubercle bacillus was demonstrated. This suggested to the author a tuberculous etiology for both diseases. In the authors' case, however, I believe the more plausible interpretation is that a tuberculoid reaction developed as the result of true leukemic infiltration of the skin, thus simulating the reaction seen in various forms of cutaneous syphilis, in which a tuberculoid reaction is frequently encountered but the etiologic agent is proved to be *Spirochaeta pallida*.

Dr. Fred Wise, New York: The authors' case is one of extreme interest, both from the clinical and from the histologic aspects. It demonstrates better than any case I have seen for a long time the futility, in certain instances, of trying to base a diagnosis on clinical grounds alone, no matter how expert a clinician the physician may be. I am sure that any one who sees a picture of this type would be unlikely to recognize the condition on clinical grounds. I should like to ask whether guinea-pig inoculations and tuberculin tests were performed, and whether there is any relationship between this picture and the famous case reported by Bruusgaard in which he was able to demonstrate tubercle tissue in biopsies from almost any area of the involved integument.

Dr. George J. Busman, Pittsburgh: As to whether or not this lesion may be due to two entities, it may be. At first we thought of a generalized lichen scrofulosorum, but the case is unique in that the blood picture has remained normal for several months and the lesions have dissolved. If this is leukemia, it is a question of what effect the spleen extract had. We are trying it in other cases. Guinea-pig inoculations and sections stained for tubercle bacilli were negative.

OUR EIGHTEENTH CENTURY METHOD OF TREATING SUPPURATIVE OTITIS MEDIA

A CRITICISM AND A REMEDY *

JOHN A. PRATT, M.D.
MINNEAPOLIS

In the past and present methods of treating suppurative otitis media, the most important factor, drainage, seems to have been ignored.

The first principle in surgery has always been, "Where pus is present, evacuate and establish drainage." In suppurative otitis media, if nature has not ruptured the drum, it is incised; but few follow up the next step and encourage continuous drainage. It is this one important step of continuous drainage on which success or failure depends.

If it were possible to drain a suppurating middle ear, attic, antrum and the mastoid cells through the eustachian tube, mastoidectomies would be very rarely performed. When the eustachian pathway is not sufficient, drainage must be established through the drum or the mastoid bone.

Following this thought of continuous drainage, a review was made of thirty-nine books dealing with diseases of the ear, published from the year 1888 until 1929. Only three of these books suggested frequent changing of cotton in the ear canal and not one of them described the method of application. Twenty of them spoke of irrigations only. Four recommended irrigations with drying of the canal. Nine gave irrigations with drying and a gauze pack for the first twenty-four hours. Three ignored any line of cleansing.

From 1911 to 1929, only three papers on suppurative otitis media were read in the American Academy meetings and only one in the meetings of the American Medical Association. Of the eleven discussions on a paper by Dr. Wolfe in 1923, mine was the only one mentioning continuous drainage.

Until Dr. M. C. Fox wrote a paper in 1929, there had been no reference made to the use of continuous drainage in suppurative otitis media since 1906: at least I have been unable to find any.

In a review of 192 papers written on middle ear diseases, published in the eye, ear, nose and throat year books from 1906 to 1929, 152 papers were negative in reference to ear cleansing. Twenty-five recommended irrigations; 6, from one to many dryings; 3, irrigations with gauze pack for the first twenty-four hours; 3, twenty-four hour gauze packs only; 2, aspirations; 1, gravity drainage.

---

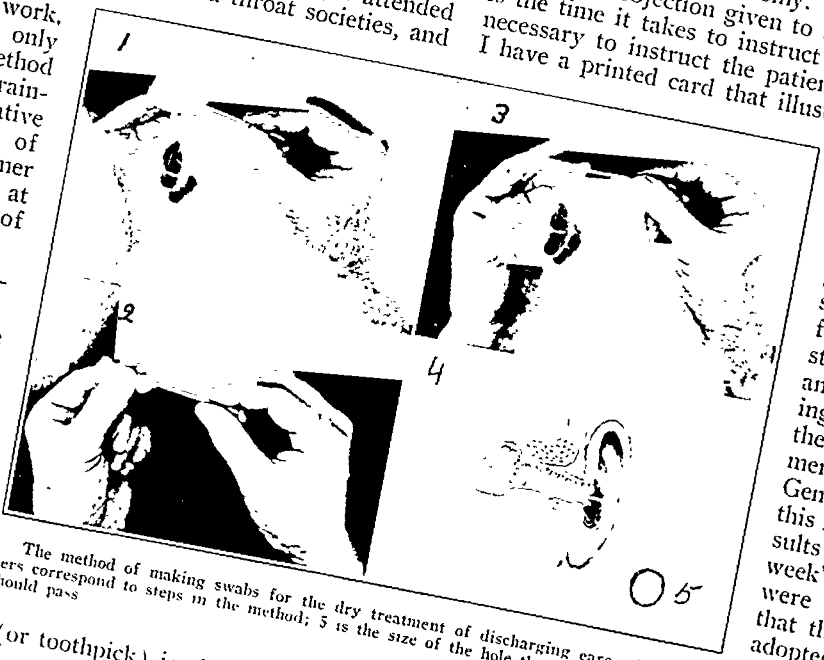
* Read before the Section on Laryngology, Otology and Rhinology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

This is not a criticism of any of the innumerable methods of treatment but of the method of drainage used after pus begins to flow into the external auditory canal.

If some still believe that medicine can be dropped into a pus-filled middle ear cavity, they should do it but should also use drainage. Continuous drainage does not interfere with any line of treatment.

The powerful suction of capillary attraction is well known. It is the use of this well known force that is employed in the dry treatment of suppurative otitis media. With a well made, elongated swab of highly absorbent cotton, all fluids in continuity can be drained. In following this fact, I have been using continuous drainage of the middle ear for the past twenty-five years, with what I consider remarkable success.

Starting January 6 of this year, at Houston, Texas, and ending March 25 at Vancouver, B. C., I attended ten meetings of eye, ear, nose and throat societies, and met hundreds of men doing special work, and yet found only two using the method of continuous drainage in suppurative otitis media, one of these being a former student of mine at the University of Minnesota.



The method of making swabs for the dry treatment of discharging ears. The numbers correspond to steps in the method; 5 is the size of the hole through which the swab should pass

METHOD OF TREATMENT

To make the swabs for the dry treatment of suppurative otitis media, the following method is used:

1. A small piece of absorbent cotton is laid on the tip of the first finger of the left hand; then the end of an applicator (or toothpick) is placed in the center of the cotton.

2. The thumb is placed lightly over the cotton and applicator (or toothpick); then with the right hand, the applicator is twirled away from one, leaving a small space between the thumb and the first finger to shape the cotton.

3. The cotton is now an evenly wound swab, about 1½ inches long.

4. The swab on the applicator is now inserted in the ear canal down to the drum and the discharge wiped out. When the canal is dry, a swab is left in the canal and this *must touch the drum*. To remove the applicator, one finger is placed on the cotton, the applicator is slightly turned in the opposite direction to loosen it, and then it is withdrawn.

5. The swab must be made small enough to pass through a medium sized ear speculum.

6. The swab should be changed as often as it is half filled with discharge, whether five minutes or five hours, the object being to suck the discharge out of the middle ear cavity as rapidly as it is formed.

The pain present in suppurative otitis media is due to the pressure of the discharge confined in the middle ear and antrum of the mastoid. With the dry treatment, one is able to remove the pus and so relieve the pressure pain. With the patient in the office for an hour, one can determine the proper outline for the treatment of the case.

It will be found necessary in acute cases to change the swabs night and day for the first forty-eight hours. The reward is a rapid recovery, free from pain, the reduction of the septic condition and avoidance of mastoiditis.

There is no doubt that the use of dry treatment and proper mastoidectomies in acute suppurative otitis media would banish chronic suppurative otitis media.

The reaction of the discharge and of the patient t the treatment is an indication of when and when no to perform a mastoidectomy.

The one objection given to this method of treatment is the time it takes to instruct the patient. It is rarely necessary to instruct the patient after the second day. I have a printed card that illustrates and describes the method of making and applying the swab. This card is given to the patient.

While in Los Angeles this winter, I spent every morning for two weeks instructing the interns and nurses and treating the patients in the outpatient department of the County General Hospital by this method. The results of the first week's treatment were so satisfactory that the method was adopted for the hospital by the eye, ear, nose and throat staff.

1753 Medical Arts Building.

ABSTRACT OF DISCUSSION

Dr. Austin A. Hayden, Chicago: The statements that Dr. Pratt makes in his paper are startling. They certainly are to me. He contemplates what I regard as continuous suction, or capillary action, through a cotton plug rather loosely fitted into the external auditory canal, and often done by the patient himself. Based on an experience, as I understand, of twenty-five years, and having treated a considerable number of cases in that time, he states that the pain is promptly relieved, suppuration is dried up, and chronicity is prevented. It seems to me that is a large order. It is a statement that I think will arouse a good deal of doubt in the minds of a great many men here The author's thesis is clear, his argument is lucid, and the paper admits of little discussion as I see it. The answer must be to try it for oneself. We have the word of an experienced otolaryngologist backed by wide experience with these cases to the effect that startling results have been obtained through a method that perhaps we have not used, at least according to the definite technic that he has followed. I might say that I doubt whether Dr. Pratt's results will be repeated by other men, but if they are a long step forward has been accomplished by this paper in the treatment of ear suppuration. If these results are not obtained by some of us when we return home we shall have to conclude that we have listened today simply to an interesting and enthusiastic report of clinical observations which we ourselves after a fair trial have been unable to reproduce.

Dr. Don M. Campbell, Detroit: One must admit at once that the ideal of perfect surgical drainage after incision or spontaneous rupture of the tympanic membrane in acute suppurative otitis media is most desirable, and one would like to agree with the author that the proper management of acute middle ear conditions and proper mastoidectomy in acute suppurative otitis media would banish chronic suppurative otitis media. However, the carrying out of such a program is not without some difficulty, for the following reasons: First, the natural timidity of people about putting anything smaller than their elbow in the ear will be found to be a deterrent to the following out of the directions in the introduction of the drain in home treatment for both cleansing and drainage. Second, the frequent introduction of the cotton applicator into the external auditory canal, down to and in contact with the drum membrane, in many cases will be found to be quite disagreeable, if not painful. On account of the extra sensitiveness of the canal and the inflamed tympanic structures this will no doubt militate somewhat against the exact carrying out of the directions by the patient in the home treatment. Third, there might be something said about the possibility of introduction of secondary infection by the continuous application of cotton-covered applicators, for though they may start sterile they might easily become infected before they reach the auditory canal and drum. Fourth, the treatment, if carried out in the office, is a time-consuming method which, of course, should not be allowed to interfere with the carrying out of such a treatment, if it can be shown that the result to the patient justifies the expenditure of time. From the surgical standpoint the use of an ideal form of drainage in the management of middle ear and mastoid diseases is highly desirable.

Dr. John F. Barnhill, Indianapolis: Adequate drainage of suppurating cavities is one of the oldest and most valuable principles of surgery. Any plan whereby free, continuous drainage from a discharging middle ear is secured is an accepted principle in otology, for unobstructed exit of the aural discharge is essential to prevent pain, hasten restoration of the infected tissue to normal, and prevent extension of the disease to adjacent structures. The author speaks of lack of proper directions in textbooks concerning methods of draining discharging ears. I feel that his statement in this respect can scarcely be justified by facts, since most modern textbooks are full and explicit on this point. In my publications on the subject I have not only described the necessity for drainage sufficiently but have in addition illustrated the methods of incision very fully. Concerning the use of the cotton cylinders as the best means of securing continuous drainage, I should have some fear that the patient in the process of inserting these with his own hands might infect them and thus reinfect the middle ear and prolong the discharge. The laity, even when instructed, seldom give strict attention to antiseptic procedures when treating themselves. I cannot agree with the statement that any known plan of treating an acute discharging ear will positively insure the patient against complications. Free drainage will usually do this, but there are instances of acute aural infection, as that following scarlet fever, in which the character of the pathogenic organism is such that complication takes place almost from the beginning, and all efforts fail to check the progress.

Dr. Francis V. Gowen, Philadelphia: During the acute stage I make a wide incision into the drum membrane and keep it open by irrigation, reincising as often as is necessary. Since the infection reaches the ear from the nasopharynx by way of the eustachian tube, a shrinking solution is dropped into the nostrils, aerating the nasopharynx, as advised by Coates, followed in five minutes by an antiseptic solution. This treatment eliminates the ideal culture mediums of the nasopharynx, viz., darkness, moisture, food and heat, destroys the bacteria in situ, and also promotes eustachian drainage. After the acute stage, prophylactic measures are instituted, adenoids and diseased tonsils are removed, and submucous resection and middle ear turbinectomy are done, if indicated. Necessary and conservative treatment as advised by Skillern is applied to the lower turbinates. Any other conditions supplying food for bacteria or preventing proper aeration of the nose and nasopharynx are remedied.

Dr. Lyman Richards, Boston: Those who are called on to deal with these conditions in the average outpatient clinic must devise some form of treatment that can be carried out at home. The time cannot be spent with these patients that physicians do in the office. Consequently, parents must be instructed as to any local treatment that seems feasible. One of the difficulties encountered has been mentioned by Dr. Campbell, matters of great reluctance on the part of parents to insert any cleansing object to the proper depth in the auditory canal. This difficulty has led me to adopt the use of a special short meshed wick, manufactured originally as a remnant from a twine mill, which, having a high capillary reaction like a lamp wick, tends to facilitate drainage from the needle here. Once properly inserted into the canal it needs changing only at intervals of forty-eight hours or more, for which procedure the child can return to the outpatient clinic. In the meantime a small piece of cotton placed on the outside where the wick comes out of the external auditory meatus can be frequently changed by the parent, thus promoting free drainage and at the same time maintaining cleanliness and comfort. This wick is efficacious principally and the discharge is serosanguineous. When it becomes purulent, the wick tends to float out with the discharge, and some form of irrigation will prove more efficacious.

Dr. Harold M. Hays, New York: One of the chief things to be considered in infections of the middle ear is the amount of drainage, and repeated observations should be made to see whether the original incision in the drum is sufficiently large for drainage. If the discharge from the ear canal is profuse, it is not necessary to insert anything into the canal to increase the discharge. All such cases should be under daily observation, preferably in the office if the patient is ambulatory, so that careful examination with an otoscope can be made in order to note the condition of the incision and particularly to note whether there is pulsation. All know that it makes little difference how large the original incision is, for within twenty-four hours most of it closes up. Rather than performing multiple incisions in the drum, one can keep the original incision open by inserting an electrical otoscope tightly into the ear canal and sucking in and out through a piece of tubing attached to the otoscope. There are certain adjuvants to treatment that are more than worth while. A small child can be placed in front of an irridescent lamp, or such a lamp can be suspended over a crib for an hour or so at a time. Patients coming into the office can be treated by inserting a small wick of cotton immersed in a mentholated solution into the ear canal and having such patients sit in front of an infra-red lamp. I shall be most happy to try Dr. Pratt's treatment in the office but can hardly feel that a lay person can be properly instructed to use it at home.

Dr. Emil Amberg, Detroit: I think Dr. Pratt's treatment, under certain circumstances, is excellent, and, like the last speaker, I would commend it, but not in the office. That is the point to which I would object in acutely infected ears. I think that a patient with such an ear should be in bed and has no business to come to the office. If the eardrum is incised and the patient put to bed, the results will be much better and there will be fewer complications. I also deprecate the introduction of irritating substances into the acutely inflamed ear after incision. The patient should have a rest, nature should be given a chance, and insult should not be added to injury. Therefore, I urge that these patients be sent home and not allowed to come to the office every day, but kept in bed and watched.

Dr. J. A. Pratt, Minneapolis: If the treatment is tried as I have described it I think it will be adopted. The people must be educated; I showed that they can be in Los Angeles last winter. In reference to the aseptic part, the patient is instructed to wash his hands, that is all. If others are doing it for the patient, they are simply told to wash their hands and keep clean. If care had to be taken about every germ that came along, no one would eat or sleep in a month. But one can keep away from terrific infection. Work in the dispensary has shown that the results are marvelous. The paper was not dogmatic. I did not say there would not be chronic suppurating ears or mastoidectomies or anything of that kind. I said that if this was done there would be less likelihood of chronically affected ears; and in my opinion they will not occur because it is the infectious material that is allowed to stay there that brings on the chronic case. This has been used in all the ear cases at the state university and dispensary, and the results are marvelous. I may be considered radical, but one who had seen the hundreds of cases that I have would think differently about it. All I ask is that it be given a trial.

Clinical Notes, Suggestions and New Instruments

POLYCYSTIC KIDNEYS WITH BILATERAL NEPHROLITHIASIS *

Alexander Hamilton Peacock, M.D.
and
Donald G. Corbett, M.D.
Seattle

Polycystic kidneys are always spectacular, on account of their unusual size, the fact that nine out of ten are bilateral, and the limitations of surgery that can be safely employed.

The occurrence of calculi in this type of kidney is scarcely mentioned in the literature. Thomas [1] reported a case of staghorn calculus in a kidney presenting multiple cysts but not polycystic. In discussing this case, Greene [2] stated that he saw a case of staghorn calculus in a polycystic kidney; no operation was done. He quoted Sieber as also having seen 8 cases of calculi in 220 polycystic cases and Braasch as having seen 4 calculi in 31 cases of polycystic disease.

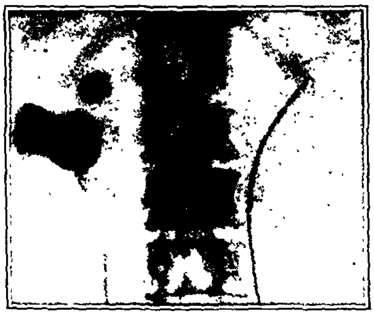


Fig. 1.—Multiple calculi in polycystic kidney.

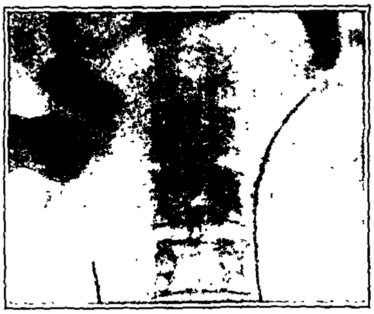

Fig. 2.—Double pyelogram of polycystic kidney containing bilateral calculi.

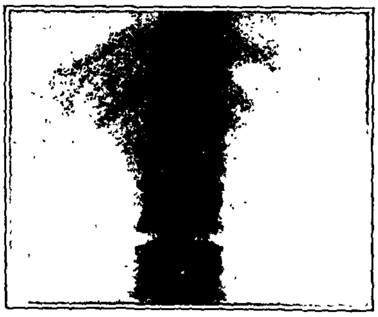

Fig. 3.—Control, Oct. 12, 1929, after removal of calculi from right kidney, showing calculi in left kidney.

Young [3] states that polycystic kidney may be the site of practically any other renal disease, as calculus, hydronephrosis, pyelonephritis or tuberculosis.

Surgery on polycystic kidneys has always carried a high rate of mortality. Brin [4] reported a mortality of 31.8 per cent in twenty-two cases of nephrotomy. Nephrectomy carries a still greater death rate.

A case of multiple bilateral calculi in polycystic kidney with successful operation was thought to be of sufficient interest to report.

REPORT OF CASE

History.—A man, aged 45, born in Nebraska, now operating a fox farm in Alaska, referred by Dr. Thomas B. Rhone of Petersburg, Alaska, was admitted to the Providence Hospital, Seattle, April 10, 1929. The patient's father died at the age of 56 of cardiorenal disease; his mother at 70 was living and well. He had two brothers living, both of whom had kidney disease, and three sisters, of whom he knew little. The patient had had the diseases of childhood. In 1900 he sustained a fracture of the left humerus and in 1913 a fractured jaw. One year before admittance, after thirty-six hours of a right renal colic, the patient passed a calculus. This was accompanied by hematuria. Three months later, another calculus escaped from the right kidney. A dull ache had been almost constant in the right upper part of the abdomen and back, occasionally radiating into the right groin. There had been no pain in the left side. Blood had been observed in the urine intermittently, sometimes a considerable quantity of it but no clots. The urine had been cloudy for several years. On standing, considerable sediment was thrown down. The urine had a strong ammoniacal odor. The patient had felt tired out and weak on exertion. He had lost weight and had little pleasure in eating. He had no gastric pains but suffered with gas after a heavy meal.

Examination.—The patient was 5 feet 9 inches (175 cm.) tall and weighed 161 pounds (73 Kg.). His temperature was 98.2 F.; pulse, 80; respiration, 18 at noon; blood pressure, systolic 160, diastolic 100. The blood Wassermann reaction was negative. Chemical examination of the blood revealed: urea nitrogen, 30 mg.; creatinine, 1.9 mg. The blood count revealed: hemoglobin, 62 per cent; erythrocytes, 3,560,000, and leukocytes, 19,050. A phenolsulphonphthalein test returned 27 per cent in the first hour and 20 per cent in the second.

The teeth were in poor condition with infected gums and many teeth were decayed. The abdomen relaxed easily. Both kidneys were easily palpable; the lower poles were below the crest of the ilium. Percussion over the right kidney produced pain.

The bladder was irritable, with a capacity of 120 cc. The urine was cloudy with a specific gravity 1.010, albumin plus, indican and sugar negative. Microscopically there were many pus cells and staphylococci; no tubercle bacilli were found. The ureters were easily catheterized, with obstruction noted near the right renal pelvis. The right kidney urine was milky in appearance and contained many staphylococci. The left kidney urine was almost clear and contained only a few staphylococci.

The control roentgenogram (fig. 1) showed a shadow in the upper right part of the abdomen which measured 3 inches long and 1½ inches wide (7.5 by 4 cm.). Above this was another shadow, ¾ inch in diameter. The left side showed a mass composed of several small, apparently faceted shadows, the whole mass being about 2 inches in length and ¾ inch in width.

The injected film (fig. 2) showed several large collections of opaque medium on the right side, one of which was superimposed on the previously described shadow, and the others surrounding it on all sides. The left side showed a greatly dilated and widely separated superior and inferior calix surrounding the previous collection of shadows mentioned.

The condition was diagnosed as polycystic kidneys with multiple bilateral calculi.

[4] Brin: Encyclopédie française d'urologie, 1914, 11,

First Operation.—April 20, under ethylene gas anesthesia, an oblique incision over the right ilium was made to give a good extraperitoneal exposure of the kidney. The latter was delivered and measured 30 by 13 by 12 cm. The surface was entirely covered with clear cysts from a pinhead in size up to 4 cm. in diameter. Several were punctured and contained pale, clear fluid. The pelvis was exposed posteriorly and the calculi were easily palpated. These were held between the fingers and cut down on. The stones were soft and had to be scooped out. The calices were easily explored with the finger. A drainage tube (24 French) was placed in the pelvis and a purse-string suture used. The wound was closed in layers.

The first night the right kidney drained 720 cc. of urine. The patient left the hospital on the twenty-first day with the wound healed, the blood pressure 130 systolic and 90 diastolic, and the weight 159 pounds (72 Kg.). The patient returned to Alaska and felt well for two months, when he began to have colic in the left side and back. These attacks were periodic and were apparently brought on by physical effort. Oct. 10, 1929, he returned to Seattle for the second operation.

Second Operation.—October 14, again with ethylene gas, the left kidney was exposed in the same manner as the right one had been six months before. The kidney was higher under the costal margin, necessitating the resection of the eleventh rib to deliver the organ. A similar picture of cysts was seen, blue, yellow and slate colored, all of different sizes (fig. 4). The ureter was isolated and the pelvis opened posteriorly. Through this incision were expressed several soft calculi and a quantity of putty-like substance. When the uppermost calculi were released, a quantity of white, creamy pus escaped. A rubber drain in the pelvis was secured with a purse-string suture. The kidney was replaced and the wound repaired.

Convalescence was placid. The patient was discharged on the twenty-fourth day; his weight was 148 pounds (67 Kg.). Feb. 1, 1930, he wrote that his weight was 165 pounds (74.8 Kg.), that the urine was at times hazy, and that he felt fine.

SUMMARY

1. Multiple calculi in bilateral polycystic kidney are exceedingly rare.

2. Surgery of the polycystic kidney should be unusually conservative.

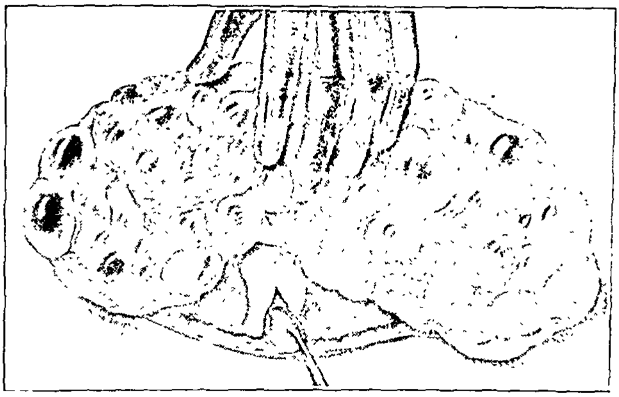

Fig. 4.—Appearance of cysts from left kidney; actual length, 11 inches (28 cm.).

3. Chronic staphylococcus infection of the urinary tract ends, frequently, in the formation of calculi.

The Control of Nature.—Human progress has been a series of triumphs over natural forces. But when anything new is proposed, certain people cry out that this is a perversion of nature. Of course it is. Man rules by bending the world to his will and to the service of his ends. Man has progressed by mastery over other forces.—Cowdry, E. V.: Human Biology and Racial Welfare, New York, Paul B. Hoeber, Inc., 1930.

A CASE OF OSTEOGENESIS IMPERFECTA INFANTILIS

JOHN INGLIS, A.M., M.D., DENVER

The mother of this child was 26 years of age. She was one of a family of eleven, all of whom were living except one child who died at 2 weeks of age of smallpox (the mother having contracted it) and one who died during the influenza epidemic of 1918. She weighed 152 pounds (69 Kg.) and was strong, healthy and well nourished. Her past history was entirely negative. The father was 24 and belonged to a family of four boys. He weighed 156 pounds (71 Kg.) and had always been well and strong. The Wassermann reaction was negative in both parents.

The pregnancy was normal in every way. The mother went into labor about 10 a. m., with pains every twenty or thirty minutes. These pains continued irregularly until 3 or 4 p. m., when they subsided to begin again at about 7:30. They then continued until the birth of the child by podalic extraction at 2:30 a. m. Breech presentation occurred, with the thighs more or less at right angles to the body.

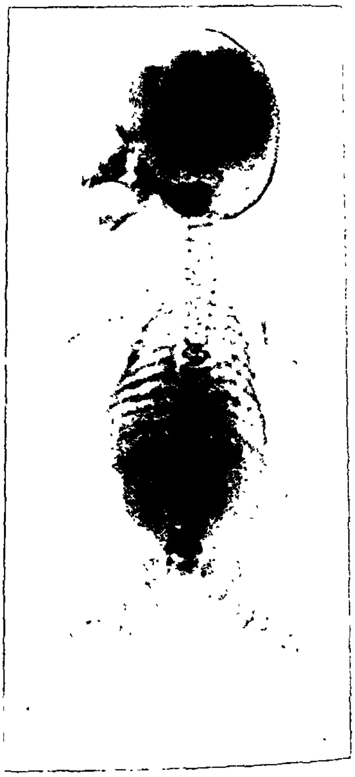

Fig. 1.—Osteogenesis imperfecta: 69 skeletal fractures, as follows: 32 costal; 20 costocartilaginous separations; 17 fractures of the extremities; comminuted eggshell fracture of skull; scapulae and pelvis poorly developed.

Great difficulty was experienced in the extraction of the child. When the legs were brought down, crepitus was felt over both the legs and the thighs. When the body was extracted, crepitus was felt over all the ribs. The greatest difficulty was found in getting the after-coming head. Dr. Evans, who was making some pressure above the pubis, remarked that he could not feel the head at all. After the head was finally extracted, it was found to be practically without a skull. This accounted for the difficulty in delivery, the usual methods only causing the head to enlarge parietally.

The child lived only a few minutes. A roentgenogram of the body showed seventy-four distinct fractures which had made an effort to unite again in the uterus.

REPORT FROM X-RAY LABORATORY

The roentgenologist reported that the condition was periosteal dysplasia. He found thirty-two rib fractures, twenty costovertebral arthrophymas, seventeen fractures of the extremities and many fractures (eggshell) of the skull. The bones of the skull, the scapulae and the pelvis were poorly developed. The spinal segments were normal.

CASES IN THE LITERATURE

This condition has been given a great variety of names. It was formerly thought to be intra-uterine rickets. This theory has been given up.

Chaumier of France reported a case in which there were 113 fractures. Most of these patients die at birth. Chaumier's patient lived thirteen days. It was delivered by a midwife.

Labor came on three weeks before term. It was a head presentation, and the baby weighed 3 pounds (1.4 Kg.).

De Paul reported a case in 1851. At that time he doubted the rickets theory.

Kassowitz of Germany reported one case. He leaned to the idea of intra-uterine rickets.

Rivière reported one case in 1911. This baby lived twelve days. Rivière thought it was syphilitic.

Getsava reported a case in 1913. As in all the others reported, the baby died.

AUTOPSY REPORT

The autopsy was performed on the body of a full term, white male infant measuring 41 cm. long and weighing 6 pounds and 12 ounces (3 Kg.).

A crescentic incision extended over the right clavicle.

There was a large amount of brown hair on the scalp. The head felt like a sac filled with fluid. Small bony plaques were in the area of the cranial bones.

There was a moderate amount of lanugo hair over the extremities. The pupils were equally dilated. The ears, nose and mouth appeared normal. There was a distinct feeling of crepitus on the midtrabecular line on both sides of the chest. The cord had dried.

There was a moderate amount of edema in the scrotum.

Crepitus was felt in both humeri, both forearms, over each femur and along the extent of the fibula. There was a slight amount of edema in the legs and feet.

The length of the right arm was 14 cm.; of the left arm, 14 cm.; of the right thigh, 4 cm. (measurement taken from the tip of the inguinal fold to the knee); of the left thigh, 4 cm. (measurement taken as for the right). The lower extremities measured 14 cm. from the tip of the toe to the upper portion of the inguinal canal.

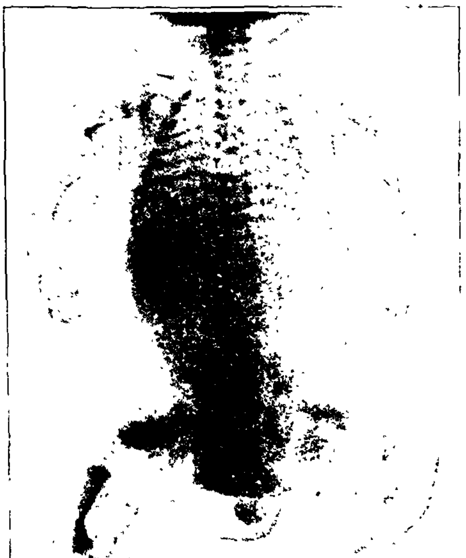

Fig. 2 Spinal segments normal.

In the abdominal cavity the position of the organs was normal. The small and large intestines were normal with little meconium present.

The pancreas weighed 2 Gm.

The liver weighed 97 Gm. It was normal in shape and size. The capsule was normal. The cut surface was also normal. The right and left suprarenal glands each weighed 3 Gm. and appeared normal. The kidneys each weighed 10 Gm. and appeared normal.

The gallbladder was normal.

The spleen was normal in shape, being as broad as it was long, with a deep notch on the anterior border. The capsule was normal. The cut surface was also normal. It weighed 8 Gm.

The thymus measured 6 by 4.5 by 1.5 cm. and weighed 12.5 Gm. The thyroid was not cystic and appeared normal.

The mesenteric glands were numerous and prominent. Otherwise the abdominal organs appeared normal. The omentum was normal.

The right and left pleural cavities and pericardial sac contained a large amount of fluid (probably embalming fluid and not hemorrhagic fluid).

The right lung weighed 16 Gm., and the left 14 Gm. Both appeared normal, as did the heart.

Along the spine was a diffuse traumatic hemorrhage with a separation between the fourth and fifth dorsal.

In the brain there was a diffuse traumatic hemorrhage around the occipital and temporal lobes above the tentorium cerebri and the cerebellum.

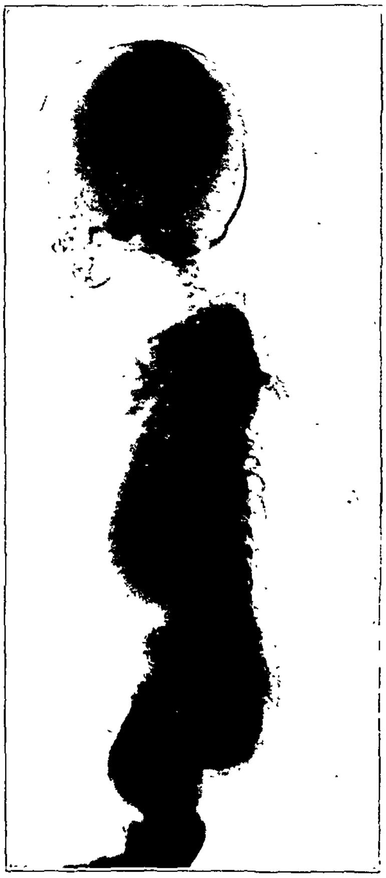

Fig. 3.—Faulty development of bones of pelvis; fractures of the extremities.

A MOTORLESS OXYGEN THERAPY APPARATUS*

Russell L. Cecil, M.D., and Norman Plummer, M.D.

New York

The value of oxygen therapy in the treatment of disease has been demonstrated in the last decade by the accumulation of extensive clinical and experimental evidence. A continuous supply of from 40 to 60 per cent oxygen has been found to be most beneficial. Administration with the funnel or the nasal catheter does not supply this optimal concentration to the lungs. The mask has been given an extensive trial but has been found unsatisfactory for continuous therapy. The oxygen chambers, as developed by Haldane,[1] Barcroft,[2] Stadie,[3] Binger,[4] Barach,[5] and others, are satisfactory but they are expensive to operate and available only to a few hospital patients.

Leonard Hill[6] recognized the importance of constructing a portable oxygen therapy apparatus that would have the advantages of continuous flow and high concentration. In 1921 he described a bed tent that satisfied certain of these requirements but that was cumbersome to move and inefficient to operate.

---

[6] Hill, Leonard Proc. Physiol. Soc. 1: [illegible]

This apparatus was modified considerably by Barach and Binger,[7] but the same disadvantages remained.

In 1926 Alvan Barach[8] described a new apparatus that was definitely more satisfactory. He incorporated the head tent idea of Roth,[9] which made it much less cumbersome. The ventilation was obtained by a small motor and fan; the air was cooled and dried by passage through cracked ice, and the carbon dioxide was eliminated by passage through soda lime. This portable therapy apparatus is the one most commonly used at the present time. However, it still presents certain mechanical difficulties, which are particularly those that have to do with the motor and the cooling system. The motor causes a certain amount of noise, is apt to stop suddenly, is dependent on an electrical connection and requires lubricating oil, which is considered dangerous when used near high pressure oxygen. The cooling system requires much attention in order to keep it filled with ice, and the leakage of water causes considerable inconvenience. In an attempt to overcome these disadvantages, the apparatus reported here has been developed.

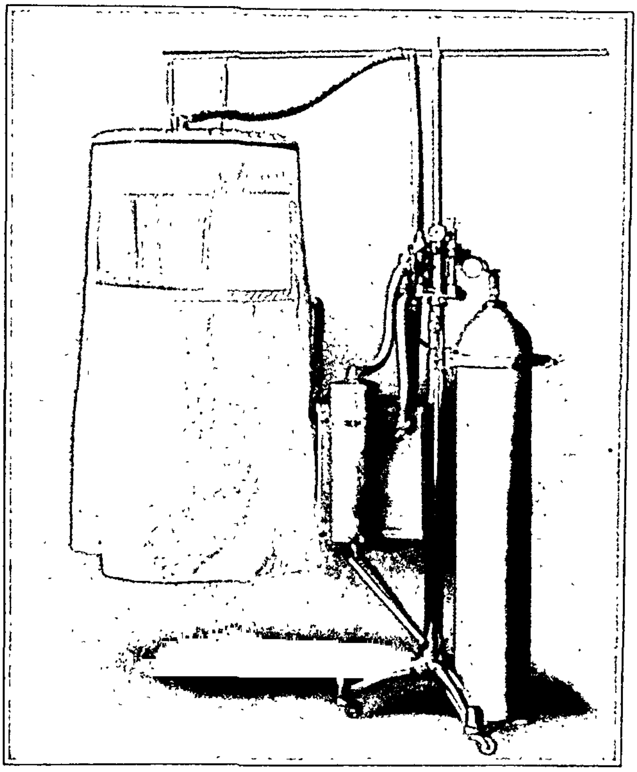

Fig. 1.—Motorless oxygen therapy apparatus, showing hood, operating mechanism and supports.

The motor blower is replaced by an injector, designed by the American Atmos Corporation. It utilizes the high pressure flow of oxygen for its motive power, drawing the air from the hood through the regenerator on the one side, and forcing it through the cooling system and back into the hood on the other. The injector may be regulated to furnish as much or as little circulation as is suitable. In this particular apparatus it is set to give an air exchange of 100 liters a minute.

The minimum oxygen requirement for this type of apparatus has been found to be approximately 5 liters a minute. For simplicity, the injector is set to use this minimum amount, which furnishes an atmosphere of about 50 per cent oxygen concentration to the patient. If a higher percentage of oxygen is required, it may be added through an auxiliary reducing valve. A gage connected to this valve registers the flow of oxygen in liters per minute. Another gage on the injector gives the pressure of oxygen in the cylinder. At the beginning of the treatment it is desirable to obtain the optimum oxygen concentration in the hood as quickly as possible. This is done by pressing a button on the front of the apparatus, which releases a quantity of oxygen and which will increase the oxygen percentage in the hood to 50 per cent in two minutes.

The carbon dioxide is removed from the air by passage through a regenerator of soda lime. This reduces the carbon dioxide in the air entering the hood to less than 0.5 per cent. The regenerator contains a sufficient amount of soda lime for more than twenty-four hours of treatment. Two types of regenerators have been used, one refillable and the other sealed. For the usual hospital practice, the refillable type is almost as handy and more economical. The sealed type is convenient when loose soda lime is not readily obtainable.

In the cooling system an attempt has been made to avoid the inconvenience of the use of ice and at the same time to produce, if possible, even greater cooling of the air. The system has been adapted to the use of "dry ice" (carbon dioxide snow), and all tests made up to the present time have proved very satisfactory. The air coming from the injector passes through the cooler, the inner walls of which form a container of the proper size to hold a 40 pound cube of "dry ice." The outer walls are double and lined with felt to afford insulation from the outside air. A water trap with a valve is placed at the lowest level of the circulatory system in order to remove the moisture that condenses from the expired air. A valve is also inserted at the bottom of the metal container to allow for the drainage of water when it is more convenient to use ice, or salt and ice. It has been found that a cake of "dry ice" will last from twenty-four to thirty-six hours. Ice and salt must be renewed every eight to ten hours.

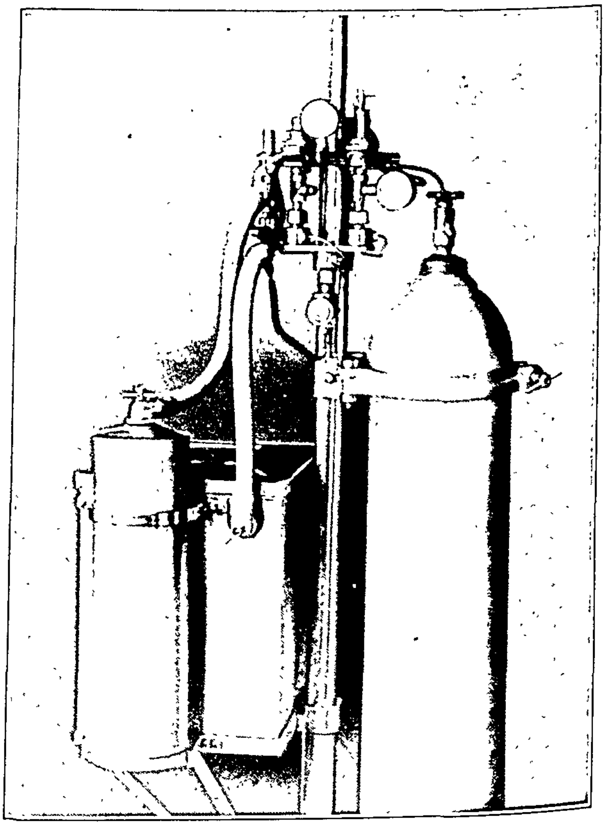

Fig. 2.—Operating mechanism of motorless oxygen therapy apparatus, showing regenerator, cooling system, injector, high pressure valve, by-pass valve, gages and oxygen tank.

The air from the cooling system passes directly into the side of the hood through a short piece of rubber tubing. This modification from the usual method of carrying the tubing to the top of the standard and thence into the top of the hood has been found to be a great improvement over the old arrangement. By this method the heating of the air by radiation from the metallic parts of the apparatus and from the room is largely prevented. With a room temperature of 73 F., the temperature of the air entering the hood was 22 F. when "dry ice" was used and 43 F. when ice and salt was the cooling substance. The air in the hood is warmer than the air entering the hood but cooler than the air of the room. At no time has a patient complained of the air being too cold.

---

[7] Barach, A. L., and Binger, C. A. L.: Portable Oxygen Tent, J. A. M. A. **85:** 190 (July 18) 1925.

[8] Barach, A. L.: New Oxygen Tent, J. A. M. A. **87:** 1213 (Oct. 9) 1926.

[9] Roth, P.: Bull. Battle Creek Sanitar. & Hosp. Clin. **19:** 178, 1924.

The hood is of the circular type as described by Roth. It is 54 inches long and 26 inches in diameter, made of a heavy rubberized material, provided with a large window and supported from the top by a conical piece of metal. The standard and cross rod are adjustable, and the hood is hung from two small springs which make the apparatus flexible and easy to manipulate. The pedestal is of substantial construction with rubber-tired casters. The oxygen cylinder is easily mounted without being lifted. The entire outfit is easily moved from one place to another as a single unit.

The operation of the apparatus is extremely simple. With the oxygen cylinder in place, the regenerator attached and the "dry ice" or ice in the cooling chamber, it requires merely the turning of the valve on the oxygen cylinder to obtain approximately 50 per cent of oxygen in the hood. This percentage may be obtained rapidly by pressing the button on the front of the apparatus, or, with the outfit running, the oxygen may be increased by turning a valve. The oxygen cylinder is renewed every twelve hours, and the soda lime and "dry ice" every twenty-four hours, or, if ice and salt are used, it is supplied every eight hours.

The portable oxygen therapy apparatus that is described here has definite advantages which may be enumerated as follows:

1. Simplicity, and therefore very slight probability of the mechanism stopping suddenly or getting out of order.
2. Elimination of the use of a motor blower, thereby avoiding (1) the noise; (2) the hazards caused by sparks from the motor and by the use of oil near high pressure oxygen; (3) the attention which a motor requires, and (4) the necessity of locating the apparatus near an electrical connection.
3. A more efficient cooling system, with the use of "dry ice" instead of ice. This eliminates the necessity of frequent drainage of the cooling system and of renewing the cracked ice every two to three hours.
4. The apparatus is easily manipulated and is designed to give efficient oxygen treatment more comfortably and more economically to the sick patient.

A CASE OF ACONITINE POISONING CAUSING CARDIAC COLLAPSE

Edward F. Hartung, M.D., New York

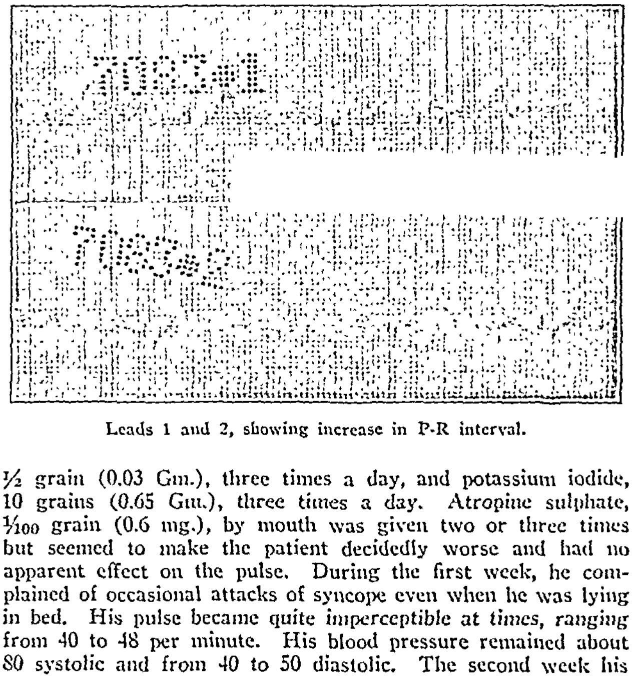
This case of aconitine poisoning is reported primarily to acquaint physicians with the possibility of its unsuspected occurrence. There are probably other cases of mild and severe aconitine poisoning throughout the United States which are being overlooked. Aconitine is a drug that finds little usefulness nowadays and naturally does not enter the physician's mind. Records of aconitine poisoning in any form are unusual in modern medical literature. In my perusal of the literature back to 1883, I could find only three case reports of aconitine poisoning in man with specific mention of its effect on the heart. There were no recent cases. Also, this is apparently the only case in man in which electrocardiographic records were obtained.

REPORT OF CASE

E. O., a merchant, aged 31, weighing about 242 pounds (110 Kg.), drank at about 4 p. m. a small amount of whisky which he had purchased a few weeks before on a steamer bound for New York. The estimated quantity taken was probably less than 3 drachms (11 cc.). The patient rarely used alcohol in any form. At first he felt exhilarated and took a long walk, but in a half hour he felt depressed and was unusually silent. He had a light dinner and then went to a theater. While in the theater about 9:30 he began to have difficulty in breathing and became quite faint, dizzy and weak. He said he felt that he was dying. He began to perspire profusely and his companion noticed that his skin was cold, white and clammy. He was given some spirit of ammonia but this failed to relieve him. Positive collapse lasted for two hours until he arrived home and was put to bed. He passed a rather uneventful night. He did not vomit or have diarrhea or any of the classic signs of aconitine poisoning, such as tingling in the mouth, stomach and skin. He did complain of moderate salivation. The outstanding factors were a great general depression and marked anxiety.

He was seen by me the following morning, and his chief complaint at that time was weakness and a feeling of faintness and uneasiness over the precordium. On examination he was outwardly normal except for the fact that he was pale and his skin was cold. His breathing was normal. The heart was enlarged slightly to the left. The sounds were almost imperceptible. There were no murmurs or other abnormal observations. The pulse was 40 per minute, weak, and almost imperceptible. The blood pressure was 75 systolic and 40 diastolic. This was difficult to obtain accurately. Electrocardiograms were taken at this time and the patient was put to bed.

Urine, serologic and chemical blood examinations were negative. The treatment was not specific at this time because I did not know that the cause of the symptoms was aconitine poisoning. He was kept strictly in bed and given general stimulating treatment, including small doses of digitalis, thyroid extract, ½ grain (0.03 Gm.), three times a day, and potassium iodide, 10 grains (0.65 Gm.), three times a day. Atropine sulphate, ¹⁄₁₀₀ grain (0.6 mg.), by mouth was given two or three times but seemed to make the patient decidedly worse and had no apparent effect on the pulse. During the first week, he complained of occasional attacks of syncope even when he was lying in bed. His pulse became quite imperceptible at times, ranging from 40 to 48 per minute. His blood pressure remained about 80 systolic and from 40 to 50 diastolic. The second week his pulse became more rapid, his blood pressure rose, and he had fewer attacks of syncope. By the end of the fourth week, his blood pressure had reached 125 systolic and 80 diastolic, his pulse ran between 60 and 80. Throughout the entire illness the patient exhibited great anxiety and panic, and complained of uneasiness over the precordial area.



Leads 1 and 2, showing increase in P-R interval.

On examination of his activities preceding the onset of his illness it occurred to me to examine the whisky that he had imbibed the afternoon of his first attack. Analysis showed this to contain an alkaloid which on further examination proved to be aconitine. How this got into the whisky is not for me to decide. The whisky was bought at a more or less public source and for this reason it is possible that other similar cases are going about unrecognized. Examination of the electrocardiograms taken about eighteen hours after the ingestion of the poison revealed sinus bradycardia. Subsequent electrocardiograms revealed an increase in the P-R interval to 28. The most marked ones are reproduced herewith.

All accurate toxicologic knowledge is derived from experiments on animals. Here is a case of bradycardia and first degree heart block due undoubtedly to aconitine poisoning. No electrocardiogram on this patient is available before partaking of the offending beverage, but he had been in perfect health and outside of a left preponderance due to obesity there is no reason for suspecting a preexisting cardiac condition. He has now returned to normal health.

THE COST OF MEDICAL CARE

The current situation so far as concerns solution of the problems of the cost of medical care is almost as *cloudy and befogged as that of five years ago.* The Committee on the Costs of Medical Care has supplied studies on which definite conclusions may be based. The numerous experiments in variations of the nature of medical practice existing in 1929 continue to exist, for the most part, although their conduct is constantly modified by new points of view, new details and the propaganda of the public press. The new experiments with clinics, hospitals, medical centers, institutes and what not are so recent that their effects are not yet measurable, nor is it possible to say whether or not similar organizations would function successfully in other communities.

The most recent publication of the Committee on the Costs of Medical Care concerns the contract medical service offered by the Endicott Johnson Company to its employees. That service is utilized by nine out of ten employees, wholly or in part. The investigation indicated apparently that a medical service so organized that there is no charge to the patient for each specific item permits wider use of medical facilities. This conclusion might be taken for granted. The study shows that in some respects contract service is the best type available but that in other respects it is below existing standards of practice. Actually, all that the Endicott Johnson Workers Medical Service demonstrates is the fact that it has been possible to establish such a service. The practitioners in the community not taking part in the contract service do as well financially as before, if not better.

In the current issue of the *Atlantic Monthly,* Mr. Evans Clark, an employee of the Twentieth Century Fund, founded by E. A. Filene of Boston, elucidates still further Mr. Filene's plan for medical guilds, which was brought out in The Journal some months ago. Mr. Clark argues for group practice, periodic examinations and health insurance. He wants specialized professional services at fixed annual fees, and he feels that it might be possible in this way with national organization to lower medical bills. Mr. Clark opposes the plan of charging more to the wealthy than is charged to the poor, notwithstanding the fact that he does not seem to have looked carefully into the basis for such charges. Actually, there is hardly a professional service available today, including that of ministers, lawyers, engineers, dentists and other professions, that does not charge on this basis. One cannot compare the importance of medical advice to a millionaire with the price of a box of strawberries. Apparently no one has raised the question as to why a lawyer will charge a millionaire more for making a will than he will a man with $100,000, when the man with $100,000 insists on distributing his money in such a fashion that the will requires twenty-five pages more than is required by the will of the millionaire who has decided to give all his money to his favorite friend. After all, the medical profession is becoming a little weary of suggestions for modification of its methods and customs by those who *have never taken the trouble to find out those methods* and customs, and the history of the reasons for their existence.

In the *Ladies' Home Journal,* Frederick L. Collins, professional writer, who has in the past discussed many subjects in many fields, now concerns himself with the high cost of being sick. His article is the kind of discussion that one might anticipate from a writer who had assembled a few references, looked at a few experiments, and attempted to draw conclusions covering the whole problem. Strangely enough, his illustrations are pictures of several of the wealthiest hospitals in New York City and do not concern the type of institution that has to administer to and care for the poor. His article is full, however, of sound but trite suggestions in this field.

Both Clark and Collins, as well as the editor of the *Ladies' Home Journal,* Loring A. Schuler, have come to the conclusion that lowering prices and state medicine are not the solution to the problem. Mr. Schuler concludes his editorial with the following significant statement:

> Much of the high cost of medical care is not due to the doctors, the system of treatment, excessive fees in nursing, hospitalization, or medical work. It is due to our own improper demands, to our expensive and usually ineffective attempts at self-medication.

In the meantime, attempts have been made to bring the most notorious experiment, the Public Health Institute of Chicago, under scientific auspices through the appointment of an investigating committee to analyze the qualities of its scientific work, and through the establishment of an advisory committee to consider ethical and social problems arising in the practice of the institution. Thus this experiment continues—tending apparently toward a form of practice that the medical profession can tolerate as safe, practical and scientific, and for the best interest of the science of medicine and the public.

The medical profession has lent itself willingly in the past and will, no doubt, lend itself willingly in the future to any experiment for solving medical economic problems that is established under good auspices, by leaders who are willing to play the game according to the rules. The rules are made primarily in the interest of the public. The individual who violates the rules in a zealous search for an answer to the problem may overstep the bounds and thereby suffer loss of his relationships to the organized medical profession. When he does so he is answerable for his own folly, since the organized medical profession has established means whereby any individual may assure himself that the system which he wishes to practice is for the public good and at the same time not a detriment to the practice of medicine. It is an aphorism that individuals pass from the scene but institutions of merit go on forever. The public must differentiate between the problem and the man. Occasionally a zealous officer of some component branch of organized medicine attempts, in his desire to uphold what he believes to be the rules of the profession, to employ extraordinary methods for the destruction of experiments. Appeals are made to public officials, the legal codes are scanned with a microscope, chambers of commerce are solicited for support and the signs of battle are kept constantly before the public. Individuals may voice personal opinions, not infrequently dictated by personal ambitions or political expediency or they may speak officially for medical organizations. The nature of the voice that speaks should always be made clear.

The great profession of medicine will go on, and the American Medical Association, established for the promotion of medical education, the advancement of medical science and the promotion of the public welfare, is not to be confused with any local issue until its official bodies have acted in relationship to such problems. The problem of providing the public with the best medical care at a price it can afford to pay has not been solved by the first three years of the five year experiment of the Committee on the Costs of Medical Care. It has not been solved by the establishment of sixty or more group clinics in the United States, by the notable success of one of these clinics or by the failure of many others. It has not been solved by the establishment of pay clinics in connection with hospitals, pay clinics established by universities, or commercial organizations organized by business men employing full-time physicians. It has not been solved by contract practice, by health insurance schemes, either compulsory or voluntary, or by the individual general practitioner. It is strange that physicians, who themselves distrust panaceas for diseases of the human body, should continually venture panaceas for the indispositions of the body politic. It is strange that public men who distrust one track systems in their commercial ventures should be willing to support similar systems for the solution of the problem of the cost of medical care.

THE ADVERTISING OF THE DENTIFRICE

The early part, of the twentieth century may be interesting historically for the fact that it witnessed the apotheosis of the tooth brush, the tooth paste and the mouth wash. It started with the slogan "A Clean Tooth Never Decays," subsequently proved to be as false as many other slogans through which high pressure advertising agencies attract the shekels of the paying public. When the competition for maximum sales in tooth brushes was at its height, special claims were made for peculiar curves of the handle, unequal pieces of the tufting, hardness and softness of the bristles and a half dozen other alleged refinements that are less matters of scientific value than choice or taste.

So far as mouth washes are concerned, their virtues may lie in a slight astringency or alkalinity, in the mildly antiseptic influence they exert for the extremely brief period in which they are in contact with the oral tissues, or more probably in the fact that they contain enough water to provide a lavage appealing to the organoleptic senses. When Feasley thumbed the dictionary and found halitosis, he gave to Listerine a sales impulse that no other mouth wash has ever been able to equal. The conception embalmed in the title of a current refrain: "If Your Best Friend Won't Tell You, Why Should I?" has a psychologic urge that has caused hundreds of thousands of hoi polloi to burn the trails to the drug counter. Nor did the fact that the combination of substances included in Listerine is relatively ineffective and will not cure halitosis lessen the stampede. Furthermore, the promoters of mouth washes, like the promoters of every other article of merchandise from grapefruit to toilet paper, have secured testimonials from all sorts of people to the effect that they themselves have been benefited by actual trial of the substance concerned.

Recently, the Food and Drug Administration of the United States Department of Agriculture has cast a critical eye over the claims for antiseptic value made for various mouth washes and gargles. It is currently reported that the owners of all these bringers of gold are rushing hither and thither to the laboratories searching for substances that really are antiseptics and that can be added to their concoctions without changing taste or color—the important qualities—that the claims may be justified.

And now for the dentifrices! Through the potent spell of the comedy of Amos and Andy, a pepsinized mixture leaped to a leading position among tooth pastes, notwithstanding the lack of value of pepsin for this purpose. Claims made for alleged alkaline or acid values in tooth pastes have been strong—by contrast, as strong as the evidence to the effect that control of acid or alkali will prevent dental caries has been feeble. The changes have been rung long and insistently on alkalinity, on "the danger line" and on the percentage of those with pyorrhea. A half dozen assorted chemists and the commissioner of health of New York assert that low surface tension means that a tooth paste will penetrate better between the teeth. The claim of special value because of low surface tension in connection with the selling of any tooth paste is one hundred per cent hokum. Any mixture of soap, glycerin and chalk, such as is available in many tooth pastes, would be equally endowed with a low surface tension.

The council on dental therapeutics of the American Dental Association has, it is reported, secured the promise of abandonment of the claims for low surface tension by the Colgate Company, and is actively endeavoring to bring other manufacturers of tooth pastes and dentifrices into the fold where claims made for products are substantiated by scientific evidence. Physicians should do all that they can to aid the American Dental Association in this campaign.

BRAIN FUNCTIONS

The problem of the localization of cerebral functions cannot be said as yet to have reached a definite solution. From the early days of scientific interest in the subject a century or more ago until the present time the pendulum of belief has swung from one extreme to another. Flourens convinced many of his contemporaries that the cerebrum is a single organ, functionally equivalent in all its parts. The subsequent work of experimentalists, notably Hitzig and Frisch and their followers, brought out "the overwhelming importance of the cortex." Before that period the corpus striatum was regarded as the great motor center, and the thalamus as the chief center of sensation. With the establishment of the highest cerebral centers in the brain cortex came extreme views of the localization of function in the brain in which the different motor and sensory areas were definitely circumscribed and separated from one another, making the cerebrum "a plurality of organs."

The more recent studies, as Howell [1] has pointed out, have tended to modify these extreme views of localization and to emphasize the fact that histologically and physiologically the entire cerebrum is connected so intimately, part to part, that, although the different regions mediate different functions, nevertheless an injury or defect in one part may influence to some extent the functional value of all other regions in the organ. The general idea of a localization of function has been accepted, he adds, but the modern view is that the cerebrum is composed of a plurality of organs, not completely separated one from the other, as taught by Gall, but intimately associated and to a certain extent dependent one on another for their full functional importance.

It is not always easy to translate the results secured from animals in this field directly to human conditions. Accidents involving the brain and surgical necessities have therefore been depended on to supplement and substantiate the conclusions that have been developed regarding the functions of the human brain. Dandy [2] of the Johns Hopkins Hospital, from a series of cerebral operations of varying character, has reached the following conclusions:

> It is possible to remove all of the right cerebral hemisphere above the basal ganglia with no appreciable disturbance of mentality; this procedure has been carried out on several occasions for the removal of extensive tumors in the right hemisphere.
>
> On one occasion both frontal lobes have been completely extirpated for the treatment of a bilateral frontal brain tumor, and following this there has been no appreciable disturbance of mentality. The patient is perfectly oriented as to time, place and person; the memory is unimpaired; he reads, writes and conducts mathematical tests accurately; his conversation is seemingly perfectly normal.
>
> Furthermore, by the excision in other cases of the left occipital lobe and of the lower third of the left temporal lobe, we can be sure that none of these regions are responsible for intelligence. The intellect, therefore, is concerned with the remaining portion of the left cerebral hemisphere and is doubtless closely related to the speech mechanism.
>
> It has been found after ligation of the anterior cerebral artery on the left side that consciousness is completely and forever lost. This does not result when the same vessel is ligated on the right side. There is, therefore, within the limits of the distribution of this vessel an area specifically concerned with consciousness. The same result follows when this vessel is occluded at the middle of the corpus callosum, indicating that the seat of consciousness is posterior to this point in the vessel.
>
> The entire body of the corpus callosum may be split in the midline without any appreciable disturbance of function. This structure is, therefore, eliminated from participation in the important functions which hitherto have been ascribed to it.

When data of this sort become more abundant in the course of time, new synthetic conceptions and a better insight into the complicated nature of human cerebration will be realized.

Current Comment

ADVERTISING AND THE DOCTOR

The giving of a testimonial for a tooth paste by the commissioner of health of New York has been made the basis of an issue as to whether or not individual physicians and the medical profession should advertise. In a day when advertising and propaganda are the great gods of the American press, medical organizations have had to do their utmost to sustain the ethical principles that have guided the profession for many years. Those principles are not obsolete. They are as necessary for the maintenance of scientific medicine, for the good of the patient, and for the public health as is the golden rule. Organized medicine has championed willingly the abolishment of mystery from medical practice. It has given freely of its services for education of the public in hygiene and for information as to the progress that medicine has made in the control of preventable disease. A few county and state medical societies have used advertising space in promoting campaigns for the public health, in attacking quackery, and in education of the public. But as yet there is little, if any, proof that such campaigns have had results warranting the money spent on them. The secretary of one of the largest component societies of the American Medical Association has urged the employment of a public relations council for each medical group, and the employment of advertising space in the press for the promotion of medical interests, but he has been guided, no doubt, by the mere fact that great commercial organizations have promoted their interests in this manner. In a few instances physicians holding memberships in medical organizations have permitted the use of their names in the promotion of products in the health field, and in but few instances have the medical societies of which they were members called them to account. The testimonial given by the health commissioner of New York apparently aroused a storm of protest—not so much because it was a testimonial as for the fact that it represented a personal opinion not supported by adequate scientific evidence, and vaunting unduly the picture and personal qualities of the testimonial giver. The question in this case appears to be not so much one of medical ethics as of scientific judgment and good taste.

THE SEMICENTENNIAL OF A GREAT DISCOVERY

The week of November 2 will mark the fiftieth anniversary of the discovery, Nov. 6, 1880, of the parasites of malarial fever by Alphonse Laveran while an army surgeon in Algiers. Not long after, Sir Ronald Ross, then of the Indian Medical Service, proved experimentally that the malaria parasite is dependent on certain species of mosquitoes for its transmission from man to man. In 1897 he discovered the Laveran plasmodia in the stomach wall of *Anopheles* that had fed on the blood of malarial patients, subsequently proving that the spores of the parasites are concentrated in the salivary glands of the insect. In 1911 the American physicians Bass and Johns of New Orleans succeeded in developing pure cultures of the parasites of malaria outside the human body. These are some of the "high spots," passed in rapid review, of a series of scientific achievements in modern medicine that have been responsible for the prevention of much human suffering and the accomplishment of undertakings that were formerly regarded as well nigh impossible. Within the half century just passed, and during the lives of many still living, the old conceptions that malaria is caused by bad air, unwholesome odors, damp night winds, or impure drinking water have been dispelled forever, even from the minds of the untutored layman. Malaria has been eradicated from parts of the world. Without knowledge of its causative parasite and insect vectors, the Panama Canal could scarcely have been completed. A distinguished writer has remarked that the whole subject of malaria has become so fully clarified that a control of the scourge has become a matter for organization and administration alone. The golden jubilee of Laveran's pioneer contribution to the etiology of malaria coincides with the three hundredth anniversary of the earliest application of cinchona bark, with its quinine content, to the therapeutic management of the disease. As Bass[1] recently pointed out in The Journal, the cinchona alkaloids still constitute the only specific remedy for malaria. The methods for its prevention depend on the recognition of its cause, discovered by Laveran.

POLIOMYELITICIDAL ACTION OF NORMAL HUMAN SERUM

The serums of persons who have recovered from poliomyelitis usually, though not invariably, have the power of killing, neutralizing or inactivating poliomyelitis virus in vitro. It is generally assumed, though without actual experimental proof, that this neutralizing power is a measure of the probable therapeutic value of such serums. Relatively few control tests have been made with normal human serums, the general assumption being that, while such serums may occasionally neutralize poliomyelitis virus in vitro, they are usually inert or of such low viricidal power as to be of little or no therapeutic interest. A quite different perspective is suggested, however, by the report of Drs. Shaughnessy, Harmon and Gordon[2] of the Department of Hygiene of the University of Chicago. These investigators worked with Berkefeld filtrates of 5 per cent emulsions of spinal cords of infected monkeys. The filtrates were mixed with equal volumes of various dilutions of normal and convalescent human serum; the mixtures were incubated two hours and then stored in the ice chest over night. The next morning 2 cc. of each mixture was injected intracerebrally into a monkey, control injections being made with incubated mixtures of the same virus plus immune and nonimmune monkey serum. Of the twelve convalescent human serums thus far tested, eight neutralized their stock filtrate in a dilution of 1:2 and five in a dilution of 1:30. That is, only 40 per cent of their human convalescent serums were effective in vitro at this higher dilution, a dilution that corresponds to the maximum feasible therapeutic dose in human medicine. Nineteen serums from family contacts and normal children over 2 years of age were tested, seventeen of them neutralizing their virus in a dilution of 1:2 and fifteen, or nearly 80 per cent, in a dilution of 1:30. The investigators conclude from these data that serums of family contacts and of normal adults and older children possess greater power to neutralize poliomyelitis virus than the serums of persons who have recovered from an attack of the disease. They suggest that it would seem worth while in the light of these results for the clinician to study the value of selected normal serums, shown by laboratory test to neutralize virus, in the therapeusis of poliomyelitis. In this connection it may be recalled that more than a decade ago occasional favorable results with untested normal human serums were reported by Zingher.[3] Of even greater theoretical interest are the few tests made with serums of normal children under 2 years of age. Of the five infantile serums thus far tested by the Chicago investigators, none neutralized poliomyelitis virus in a dilution as high as 1:10. Contrast this with the nearly 90 per cent neutralization at 1:10 dilution with the serums of normal children over 2 years of age. This observation seems to indicate that, in poliomyelitis, immunization of the normal infantile population proceeds in much the same way as is the case in diphtheria.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10:15 on Tuesday, and 10 on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

October 27. Not So Long Ago And Now.
October 28. What About Goiter?
November 1. Protecting the Mind of Childhood.

Five Minute Health Talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

October 27. Whither Goest Thou?
October 28. What Troubles Your Mind?
October 29. The Increasing Automobile Toll.
October 30. Worry Warps the World.
October 31. Be Sensible.
November 1. Sensible First Aid.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Personal.—Dr. Grafton Elliot Smith, professor of anatomy, University of London, England, will lecture at the University of California, November 18-19, on "Peking Men and Evolution of the Human Brain." Dr. Smith has held the position of professor of anatomy at the Universities of London and Manchester, and the Egyptian Government School of Medicine, Cairo, Egypt.

State Fair Exhibit.—The exhibit of the state department of public health in the educational building at the state fair held in Sacramento consisted of charts and models, illustrating the trend of births and deaths in the state. It was estimated that between 150,000 and 200,000 people visited the exhibit. Literature on public health subjects were distributed to all who expressed interest in the subject.

Society News.—The eighty-third semiannual meeting of the Southern California Medical Association will be held in the Hotel Virginia, Long Beach, October 31-November 1. The program includes "Deafness—A Vital Social, Economic and Medical Problem," Dr. F. L. Rogers, Long Beach; "The Dietary Factor in Kidney Disease," Dr. Noel F. Shambaugh, Long Beach; "Senility—Cause and Prevention," Dr. Paul B. Roen, Los Angeles; "Indications for Use of Special Tests by the Practitioner," Dr. Arthur L. Bloomfield, San Francisco; "Diagnosis and Treatment of Carcinoma of the Colon," Dr. James Tate Mason, Seattle; "Safety Margin in Nitrous Oxide-Oxygen Anesthesia," Dr. Harry K. Bonn, Los Angeles; "Nonoperative Treatment of Steer-Horn and Fish-Hook Type of Stomach," Dr. Harlan Shoemaker, Los Angeles; "Pyloric Stenosis," Drs. Burns S. Chaffee and Cleon C. Mason, Long Beach; "Chronic Meningococcic Septicemia," Dr. Fred B. Clarke, Long Beach; "Recent Developments in Our Knowledge of the Adrenals and Their Clinical Application," Dr. Burrell O. Raulston, Los Angeles; "Present Status of the Surgical Treatment of Benign Lesions of the Stomach and Duodenum," Dr. Verne C. Hunt, Los Angeles. Dr. Clay Ray Murray, New York, will present a talking motion picture entitled "Pott's Fracture," and Dr. Alfred C. Reed, San Francisco, an illustrated travelogue through Asia, "Tropical Diseases."——The San Francisco Pathologic Society was addressed, October 6, by Drs. Harold Brunn on "Echinococcus Cyst of the Liver"; Fred Firestone, "Hepatic Degeneration with Obstructive Type of Jaundice"; Stacy R. Mettier, "Hepatic Cirrhosis in a Young Woman"; Gordon E. Hein, "Macrophage Showers"; Alson R. Kilgore, "Unusual Goiters," and Edwin L. Bruck, "Epithelioma of the Stomach."——The Los Angeles County Medical Association was addressed, October 16, by Drs. Donald J. Frick on "The Heart in Diseases of the Thyroid Gland"; Oscar Reiss, "Report of 180 Cases of Poliomyelitis with Review of Present Epidemic," and Edward C. Moore and Donald G. Tollefson, "Hysterectomy."——The Los Angeles Trudeau Society will be addressed, October 28, by Drs. Edward W. Hayes, Monrovia, and John Dwight Davis on "The Practical Application of the Recent Classification of Tuberculosis in Children" and "Pathologic Changes of Lymph Nodes in Experimental Tuberculosis," respectively.

ILLINOIS

Society News.—The Taylorville Physicians' Club was addressed, September 24, by Dr. Perry E. Duncan, Chicago, on "Eye Injuries."——The Madison County Medical Society was addressed at Granite City, October 3, by Drs. Leslie D. Darner on gas poisoning, and Quitman U. Newell, St. Louis, cancer of the uterus.——At the annual meeting of the Tri-County Medical Society (Warren, Knox, Henry), October 13, at Galesburg, the speakers were Drs. Alexander A. Goldsmith, "Chronic Colitis"; Rollo K. Packard, "Surgical Mortality and Morbidity"; Edward L. Cornell gave an illustrated talk on obstetrics.

Chicago

Personal.—Dr. Le Roy Thompson was appointed chief of staff of the Illinois Charitable Eye and Ear Infirmary by Governor Emmerson, August 1, succeeding Dr. William L. Noble, and Dr. James L. Smith was appointed superintendent of the institution to succeed Dr. Leo Steiner.——Dr. Archibald V. Hill, Foulerton research professor of the Royal Society, London, England, lectured on "The State of Water in Tissues" at Northwestern University Medical School, October 20.

Society News.—The second William T. Belfield Lecture was given before a joint meeting of the Chicago Medical and Urological societies, October 22, by Dr. Edward L. Keyes, New York, on "Preventable Infections Incident to Preparing a Prostatic for Operation."——Dr. Joseph A. Capps delivered the presidential address before the Chicago Pathological Society, October 13, on "Pathogenesis of Cardiac Pain"; Dr. Harry Gideon Wells spoke on "Addison's Disease with Selective Destruction of the Suprarenal Cortex"; Dr. Phillip F. Shapiro, "Pathogenesis of Glomerulo- and Arterio-Necrosis in Malignant Nephrosclerosis," and William M. McGrath and Dr. Carl W. Apfelbach, "Spontaneous Bilateral Decapsulation of the Kidneys."——Dr. Ida C. Mann, London, England, addressed the Chicago Ophthalmological Society, October 13, on "Embryology of the Eye."——The Medical History Club of the College of Medicine of the University of Illinois opened its fourth season of public lectures, October 15. Dr. William F. Petersen spoke on "Count Struensee"; these lectures are held in the library of the college of medicine on the first and third Wednesdays of each month at 1 p. m.

INDIANA

Society News.—Dr. Bransford Lewis, St. Louis, addressed the Terre Haute Academy of Medicine, September 5, on "Movable Kidney."——The Floyd County Medical Society was addressed, October 10, at New Albany, by Dr. William F. Edwards on "Focal Infection."——Dr. Austin A. Hayden, Chicago, addressed the Indianapolis League for the Hard of Hearing, September 30, on "How the Handicap of Deafness May Be Overcome."

IOWA

Board of Health for University.—The board of health for the University of Iowa, authorized by President Walter Jessup, was recently organized and its divisional work inaugurated with headquarters at the student outpatient service offices. The personnel includes Dr. Henry S. Houghton, professor and dean of the college of medicine, chairman; Dr. Fred M. Smith, professor and head of the department of theory and practice of medicine; Dr. Milford E. Barnes, professor and head of the department of hygiene and preventive medicine, secretary, and Carl E. Seashore, Ph.D., head of the department of psychology and the graduate college; Robert E. Rienow, dean of men; Miss Elizabeth Halsey, professor and head of the department of physical education for women, and Edward H. Lauer, Ph.D., professor and director of the division of physical education. With the approval of Dr. Daniel C. Steelsmith, state commissioner of health, the university board will enforce regulations of local health officers and remove possibilities of menace to health arising from the existence of the hitherto "no man's land" in the form of state owned properties. The activities of the new board will include the inspection division, under the direction of Jack J. Hinman, Jr., assistant professor of sanitation and chief of the water laboratory, which will carry out the sanitary inspection of all buildings under the direction of the quasi control of the university and all water, milk and food supplies and swimming pools. The communicable disease section, under Dr. Carl F. Jordan, assistant professor of hygiene and preventive medicine, will investigate and act on all reportable and communicable diseases within the university health district; those cases involving extramural action will have close cooperation with the local health authorities. The life extension division, under Dr. Chester I. Miller, chief of the student outpatient department, and Drs. L. B. Hanson and Grace E. Williams, examiners for men and women, respectively, will handle students, nurses and employees. The health examinations now required of all freshmen will be extended to include all incoming registrants and all prospective graduates during their final year. The student outpatient department will be supervised by Dr. Miller and will care for student illnesses, and those in need of additional service are referred to the hospital, for which a nominal charge is made.

KENTUCKY

Section Holds Annual Dinner.—The tenth annual session of the eye, ear, nose and throat section of the Kentucky State Medical Association was recently held in Louisville. Dr. Gaylord C. Hall, Louisville, presented his annual address on "Acute Retropharyngeal Abscess in Infants and Young Children." The guest of honor, Dr. John F. Barnhill, Indianapolis, spoke on "Headaches." The program included papers, among others, by Drs. Joseph A. Stucky, Lexington, on "Upper Respiratory Tract as a Guide to Nutritional Disaster—A Discussion of the Jarvis Syndrome"; Claude T. Wolfe, Louisville, "History and Diagnosis of Trachoma"; David L. Salmon, Madisonville, "Deformities of the Nasal Septum and Their Correction"; Harry D. Abell, Paducah, "A Questionnaire on Some of the Problems Concerning Tonsillectomy"; Will R. Pryor, Louisville, "Tuberculosis of the Larynx—Treatment with Actual Cautery"; Roy Glen Spurling, Louisville, "Diagnosis and Treatment of Brain Abscess," and Greenbury B. Brown, Jr., Lexington, "Causes of Bleeding from the Throat." Dr. William P. Drake, Bowling Green, was elected president.

MARYLAND

Another Cancer Clinic.—A cancer clinic was opened at the University of Maryland Hospital, Baltimore, October 6. It is located in the dispensary of the hospital at Lombard and Greene streets. The service will be free to all except those able to pay for diagnosis and treatment.

Dr. Doull Resigns.—Dr. James A. Doull recently resigned his position as coordinator of the study of common cold, which is being conducted at Johns Hopkins University School of Hygiene and Public Health, to become professor of hygiene and public health at Western Reserve University Medical School. Dr. Doull had been granted a leave of absence as professor of epidemiology at Johns Hopkins to carry on this work. The Chemical Foundation, a few years ago, gave $195,000 to the school of hygiene and public health for an exhaustive study of the origin, nature and possible cure of the common cold (The Journal, Jan. 21, 1928, p. 212; Aug. 4, 1928, p. 326). Dr. Vivian A. Van Volkenburgh, who has been a member of the staff of the school of hygiene and public health for several years, has been chosen to succeed Dr. Doull.

Society News.—The Baltimore City Medical Society held a symposium on duodenal ulcer, October 3. The society was addressed, October 17, among others, by Drs. Max Kahn on "The Question of Preoperative and Postoperative X-Ray Treatment of Cancer of the Breast," and Edward A. Looper, "Foreign Bodies in the Esophagus and Bronchi."——The semiannual meeting of the Medical and Chirurgical Faculty of Maryland was held in Westminster, October 22, at the Western Maryland College. Addresses were given by Drs. Frederick W. Wright on "The Entente—The Relationship of the General Practitioner and the Small Town Country Hospital to the Large Medical Center"; Charles C. Habliston and Thomas B. Aycock, "Phrenicotomy in the Treatment of Pulmonary Disease,"; Albert Austin Pearre, "Symptomatology of Hypothyroidism in the Adult," and William Francis Rienhoff, Jr., "Gastroduodenostomy."

MISSISSIPPI

Dr. Crider Goes to Jefferson Medical College.—Dr. Joseph O. Crider, dean and professor of physiology and histology at the University of Mississippi School of Medicine, University, resigned to become associate professor of physiology and assistant dean in the Jefferson Medical College, Philadelphia, where he assumed his new duties, September 22. Dr. Crider has been succeeded at the University of Mississippi by Dr. Philip L. Mull, professor of anatomy at the school.

NEBRASKA

Society News.—The Madison Five Counties Medical Society was addressed, August 26, by Drs. John J. Keegan on "Neuritis and Neuralgia," and Howard B. Hamilton, Omaha, "The Acute Abdomen in Young Children."——"Nephrosis" was the subject of Dr. Clark L. Phillips, Dixon, before the Cedar, Dakota, Dixon, Thurston and Wayne Counties Medical Society at Randolph, August 21. Dr. Paul F. Siman, Wayne, spoke on "Use of Foreign Protein in the Treatment of Peptic Ulcer"; Dr. Glen E. Peters, Randolph, "Undulant Fever" and Dr. Jacob N. Lande, Sioux City, "Some Diseases of the Skeleton in Infants and Children."——The Otoe County Medical Society was addressed at Nebraska City, September 8, by Drs. John Clyde Moore, Omaha, on "Serum Immunization in Children," and Abraham E. Bennett, Omaha, "Early Diagnosis and Treatment of Anterior Poliomyelitis"; Dr. Willis H. Taylor, Omaha, gave a screen lecture on some obstetric problems.——The Ninth Councilor District Medical Society was addressed at Grand Island, September 9, by Drs. Robert D. Schrock, Omaha, on "Fractures at the Elbow"; Eugene C. Foote, Hastings, "Eye Conditions in India"; Eli A. Watson, Grand Island, "Surgery of the Upper Abdomen," and Ernest Kelley, Omaha, "The Mechanism of Hysteria."

NEW JERSEY

Society News.—The Bergen County Medical Society was addressed, September 9, by Drs. Henry F. Helmholz, Rochester, Minn., on "Ketogenic Diet Treatment in Epilepsy"; John L. Morse, Boston. "Diagnosis and Prognosis in Pediatrics," and Russell Burton-Opitz, "Clinical Significance of High and Low Blood Pressure."——"Accessory Sinus Disease and Its Relation to Hay-Fever and Asthma" was the subject of Dr. Philip S. Stout, Philadelphia, before the September 10 meeting of the Burlington County Medical Society, and "Methods of Diagnosis of the More Common Diseases of the Ear," by Dr. Edward B. Gleason, Philadelphia.

Examination of Food Handlers.—The semiannual examination of all food handlers required by state board of health regulations, conducted by the Newark Department of Health, has been extended locally to include all domestic employees. Restaurant and kitchen employees must go to the department of health's clinic with the exception made for a few large department stores and insurance companies where complete clinical facilities are available. Ninety per cent of all other food handlers, including grocers, milk dealers, confectioners, bakers, butchers, soda dispensers and domestic employees, are examined at the clinics of the health department, but they have the option of examination by private physicians, who must use special blank forms. Examination for venereal diseases is made of all males. Routine swabs or cultures are not taken except when indications call for other specimens or a Wassermann test.

NEW YORK

Conference on Public Relations.—Thirty-one counties were represented at the first conference of the chairmen of public relations committees of county societies, held at Albany, September 18. Dr. James E. Sadlier, Poughkeepsie, chairman, outlined the work of the committee to consist of informing local physicians about services being conducted in the county, to establish a foundation for future health services by expanding work already undertaken, and to start new projects. The committee aims to establish cooperation between local physicians and volunteer health organizations and to promote a health survey of each county. The survey of Oswego is the fifteenth made under the auspices of this committee. Among its noteworthy results, especially in the cities of Fulton and Oswego, are the maintenance of a city welfare nurse to offer free services to families needing instruction in hygiene and care of the home and the child; the holding of prenatal clinics once a week, and the maintenance of a tuberculosis nurse for the investigation of potential cases and free hospital provision for needy cases. The society cooperates with lay organizations in supplying free milk to poor undernourished children and in the campaign against diphtheria and smallpox. The child hygiene station and prenatal clinic training station for state welfare nurses was established and two specialists a month conducted clinics for children with mental deficiencies and for crippled children. Recommendations were made that efforts be directed to have all milk pasteurized and improvements made in the water supply and sewage disposal, and the establishment by the county of a dental clinic meeting alternately in Fulton and Oswego. The committee asked that physicians in localities where clinics are to be held should offer their services for a small consideration to be paid by the county in order to establish a permanent service to persons who cannot afford regular treatment.

New York City

Appropriations for Hospitals.—The board of estimate recently appropriated $600,000 for the immediate construction of buildings to house 800 additional tuberculosis patients, 503 of whom now await admission to city hospitals. The city hospital commissioner, Dr. J. G. William Greeff, in July had asked for $300,000 to build four fireproof pavilions at the farm colony on Staten Island for tuberculous patients, but when it was found that there was a great increase in the number of patients, provision for 800 additional beds were made without delay. The board also voted $300,000 for the reconstruction of the Brooklyn Cancer Institute. The commissioner stated that every institution for the treatment of tuberculosis is overcrowded with 10 per cent more patients than beds in the institutions. He reported that the number of city patients suffering from various diseases at its lowest ebb this year exceeded the highest number cared for last year. In the first six months of this year, 167,000 more visits were made to outpatient departments than in the whole of 1929. The daily census of the twenty-six institutions in the hospital department showed 1,500 more patients than were cared for last year.

Increase in Welfare Work.—The expenditures of relief funds by all social agencies of the city from 1910 to 1926 for health work increased from $136,000 to $466,000, and to help handicapped persons, from $10,000 to $278,000. The Welfare Council reports that the funds available to the thirty-eight principal organizations engaged in assisting persons in their own homes increased from $2,000,000 in 1910 to about $9,000,000 in 1926. The income of New York's privately supported relief agencies increased 300 per cent in seventeen years, and the income from municipal relief funds increased 2,500 per cent. Five per cent of the income comes from bequests and 76 per cent represents contributions from living persons and organizations. The trend of relief work is to enable individuals and families to solve problems that make them social work cases. Agencies have set up "sheltered workshops" where cripples, convalescents and other physically and mentally handicapped persons are enabled to support themselves fully or partially by work.

Society News.—Among the exhibits illustrative of phases of "Medical and Surgical Aspects of Acute Bacterial Infections" given at the third annual graduate fortnight at the New York Academy of Medicine, October 20-31, are those on undulant fever, Rocky Mountain spotted fever and tularemia through the courtesy of the National Institute of Public Health; dysentery, subacute bacterial endocarditis and colitis from the Army Medical Museum. Recent advances in bacteriology such as microbic dissociation and the Schwartzman phenomenon will be shown, and there will be a demonstration of bacteriophagy by Dr. Felix d'Herelle, New Haven, Conn.; postpartum infections from the Long Island College Hospital; subacute endocarditis, new type of bacterial toxins, and pathways of infections to the ear, from the Rockefeller Institute.——The twenty-fifth anniversary of the New York Society of Anesthetists, October 16-18, was addressed, among others, by Yandell Henderson, Ph.D., New Haven, Conn., on "The Anesthetist Therapeutist"; Dr. Irving L. Farr, Montclair, N. J., "The Psyche in Anesthesia"; Dr. Anna M. Stuart, Elmira, N. Y., "The Anesthetist Himself," and Dr. William Branower, New York, "General Anesthesia for Laryngectomy."

OHIO

Personal.—Dr. Harry L. Rockwood, commissioner of health of the city of Cleveland, has recently been announced as the new superintendent of the Mount Sinai Hospital. He will be succeeded by Dr. Harold J. Knapp. Dr. Rockwell has held the position of commissioner of health for twelve years.——Dr. Asher T. Childers, psychiatrist for Cuyahoga County Juvenile Court for the last two years, has been appointed chief of the psychiatric staff of Michigan.——Dr. Jackson Searles, Lisbon, has retired from medical practice to become a member of the faculty of the Ball State Teachers' College at Muncie, Ind. ——A complimentary dinner was given by colleagues to Dr. Valentino B. Di Loreto on his completion of twenty-five years in the practice of medicine in Steubenville.——Dr. Walter E. List, superintendent of the Minneapolis General Hospital, has been named superintendent of the Cincinnati Jewish Hospital.

Society News.—The Athens County Medical Society was addressed, October 6, by Dr. William Mithoefer, Cincinnati, on "Practical Points in Nasal Accessory Treatment."——The Toledo Academy of Medicine was addressed, October 3, by Dr. Jacob L. Bubis, Cleveland, on "Relation of Gynoplastic Repair to Modern Obstetrics."——A joint meeting of the Toledo Academy of Medicine and the Clinical Orthopedic Society will be addressed, October 31, by Dr. George W. Hawley, Bridgeport, Conn., on "Newer Apparatus in Treatment of Fractures of the Femur."——The Academy of Medicine of Cleveland was addressed, October 10, by Drs. Moses E. Blahd on "Spinal Anesthesia," and George Grey Turner, professor of surgery, University of Durham, and Hunterian professor and member of the council of the Royal College of Surgeons of England, Newcastle-on-Tyne, "Ruptured Gastric and Duodenal Ulcers." ——Dr. Franz Knoop delivered the twenty-third Hanna Lecture in the Institute of Pathology, Cleveland, on "The Significance of Intermediary Metabolism." Dr. Knoop is director of the Institute of Physiological Chemistry at the University of Tübingen, which professorship is said to be the oldest in Germany having been founded for Hoppe-Seyler.——Dr. Stuart Pritchard addressed the Eighth District Medical Society at Newark, October 2, on "Significance of the Cough as a Symptom." Dr. Pritchard made the trip from Battle Creek in his own monoplane.

OREGON

State Medical Election.—At the annual meeting of the Oregon State Medical Society, Portland, September 17-19, Dr. Thomas E. Griffith, The Dalles, was installed as president; Dr. Edward L. Zimmerman, Eugene, was made president-elect; Drs. Harvey J. Clements, Salem, John H. Fitzgibbon, Portland, and William T. Johnson, Corvallis, vice presidents; Drs. Richard H. Wellington and Frederick D. Stricker, Portland, treasurer and secretary, respectively, reelected. The next annual meeting will be held at Eugene. The revision of by-laws provided among other things the redistricting of the state into councilor districts. In the last four years, the society membership has increased more than 40 per cent.

PENNSYLVANIA

Fund for Institute of Mental Hygiene.—The Julius Rosenwald Fund has announced that a fund has been set aside to fill half of any deficit incurring up to a total of $17,500 for the first six years of the operation of the Mental Hygiene Institute of Pennsylvania Hospital. The purpose of the institute is to bring psychiatric service within the reach of persons of moderate means. In this country about 400,000 hospital beds are now used for mental patients.

Society News.—The Tenth Councilor District Medical Society and the Allegheny County Medical Society met jointly, October 21, and were addressed by Drs. John A. Heberling on "Diagnosis and Treatment of Early Joint Diseases"; George A. Holliday, "Arthritis in Infections of the Genito-Urinary System"; Paul B. Steele, "Acute Suppurative Arthritis," presentation of cases; Dewayne G. Richey, "Focal Infection in Rheumatic Fever, as Viewed by the Laryngologist," and Philip S. Hench, Rochester, Minn., "Clinical Consideration of Chronic Arthritis" and "Recent Progress in Study and Treatment of Rheumatic Diseases," illustrated.

Philadelphia

Personal.—Honorary degrees conferred at the celebration of medical progress at the University of Pennsylvania, October 10, included Surg. Gen. Hugh S. Cumming, Drs. James Ramsay Hunt, New York, William Gerry Morgan, Washington, D. C., Alfred Stengel, Alonzo Englebert Taylor, Stanford University, Calif., and William H. Welch, Baltimore, and Prof. Archibald V. Hill and Sir Walter M. Fletcher, London, England.

Prize in Pediatrics.—The Philadelphia Pediatric Society announces a prize competition to stimulate interest in pediatrics among practitioners of less than six years since graduation and residing in the Philadelphia metropolitan area. Investigations and studies to be presented must be limited to pediatric subjects. The first prize will be $100 and the second, $50, if the subjects submitted are of sufficient merit. Completed papers must be in the hands of the chairman of the prize committee, Dr. Percival Nicholson, 16 West Montgomery Avenue, Ardmore, Pa., not later than November 15.

Research on Heart Disease.—The Robinette Foundation of the University of Pennsylvania has opened a new method of research in diseases of the heart. It was developed in connection with the study of the nature of the contraction of the heart muscles in which the electrocardiograph is synchronized with roentgen photography of the heart's movements. In this new field it is possible to time accurately any point on the curve of movement within one one-hundredth of a second of the corresponding event on the electrical curve of action.. It has been found that certain types of diseases of the heart cause characteristic alterations from normal in curve of contact. In applying the technic of the study of the aorta, it is possible *to obtain* photographic records of human pulse waves and thus study the beginning of arteriosclerosis. The foundation, endowed by Edward Robinette, announced other projects at the celebration of medical progress at the University of Pennsylvania, October 10-11. Among these are studies of various social and economic groups, among which are 150 executives of a great corporation who carry the largest responsibilities, to determine the normal heart. The study of the familial relationships of heart disease has been instituted *in heart clinics* of the Pennsylvania Hospital with the support of the foundation. All available members of the family are given careful physical and mental examinations and subjected to laboratory tests to ascertain the influence of heredity on heart disease. The director of the Robinette Foundation is Dr. Charles C. Wolferth, assistant professor of medicine.

Society News.—The Philadelphia Academy of Surgery was addressed, October 6, by Drs. Irvin E. Deibert, Camden, N. J., and Francis C. Grant on "Observations on the Treatment of Osteomyelitis by the Orr Method" and "Results of Chorodotomy for the Relief of Pain," respectively.——The Pathological Society of Philadelphia was addressed, October 9, by Dr. Franz Knoop of the University of Tübingen on "Mutual Transformation of the Foodstuffs and Fixation of Nitrogen in the Body." ——Drs. James S. Plant, Newark, N. J., and Max Levin addressed the Philadelphia Psychiatric Society, *October 10*, on "Importance of an Adequate Cause in the Prognosis of Praecox Types of Reaction" and "Archaic Mental Pneumonia as a Defense Reaction in Schizophrenia."——The October 8 meeting of the Philadelphia County Medical Society was given over to a symposium on the blood diseases; the speakers were Drs. Max M. Strumia, John Eiman, Harold W. Jones and William P. Belk.——The Philadelphia County Medical Society devoted its meeting, October 22, to a discussion of "Recent Applications of the Fundamental Sciences to Certain Medical Problems"; the speakers were Wilder D. Bancroft, Ph.D., "Some Recently Demonstrated Protein Reactions of the Nerve Tissues"; William Seifriz, Ph.D., "Medical Aspects of Certain Plant Reactions"; Dr. Stuart Mudd, "Studies of the Mechanism of Antibody Action"; Dr. Seymour Dewitt Ludlum, "Medical Principles in Neurological Diagnosis," and Dr. William Egbert Robertson, "Discussion of the *Principles Presented and Their* Relation to General Medicine."——Among others, Dr. William Jackson Merrill addressed the Philadelphia Pediatric Society, October 14, on "Appendicitis Simulating Acute Arthritis of Hip."——The West End Medical Society was addressed, October 15, by Drs. Joseph Bank and Samuel J. Goldberg on intestinal flatulence and bronchitis, respectively.

VIRGINIA

Continuation Courses for Practitioners.—The Norfolk County Medical Society's series of October meetings will mark the first anniversary of the continuation education course for practitioners conducted by the department of clinical education of the state medical society. The Norfolk County Medical Society was addressed, October 13, by Drs. Thomas V. Williamson on "Emergency Cystoscopy in Ureteral Calculus," and George W. Schenck, "Some Observations on Head Injuries." No attempt has been made to give comprehensive courses or fundamental basic science courses. These will be left to the regularly organized graduate courses of the medical colleges. The aim has been to teach the medicine of today to the general practitioner mainly by practical and nonoperative clinics and clinical conferences held in his own immediate vicinity. Addresses were given, October 20, by Drs. Walter B. Martin on "The Value of Iron in the Treatment of the Anemias"; October 23, Allie D. Morgan, "Treatment of Convergent Strabismus"; Levin F. Magruder, "Technic of Localization of Foreign Bodies in the Eye," illustrated; L. Leroy Jones, Portsmouth, "Treatment of Foreign Bodies Imbedded in the Cornea and Complications"; October 27, Dandridge P. West, "Three Years' Experience with Goat's Milk in Infant Feeding," and William L. Harris, "What Progress in Infant Feeding?" A course in practical psychiatry for students of the Medical College of Virginia will be given at the Central State Hospital at Petersburg. This is the second year that the state hospitals of *Virginia have been opened publicly to the medical profession for* clinical instruction. Members of the state society are requested to write for any information concerning the extension courses in graduate medical education to the chairman of the department of clinical education, 5 East Franklin Street, Richmond, or to Mr. George W. Eutsler, P. O. Box 707, University.

WISCONSIN

University News.—Student infirmary facilities at the University of Wisconsin will be virtually doubled by the recent action of the board of regents when it was decided to construct an addition to the present infirmary at a cost of $100,000. The student health and infirmary fee was increased to $4.50 a semester.

Personal.—Dr. William T. Pinkerton has resigned as medical director of the Prairie du Chien Sanatorium, a post which he has occupied, with one short interlude, for more than twenty-six years. Dr. Pinkerton, it is reported, will devote all his time to private practice.——Dr. John H. Connell, Beloit, has accepted a position as junior pathologist in the department of medicine of Tulane University of Louisiana, New Orleans.

State Medical Election.—At the annual meeting of the State Medical Society of Wisconsin, September 11, Dr. Cornelius A. Harper, Madison, was installed as president and Dr. Otho A. Fiedler, Sheboygan, made president-elect. The secretary will be elected by the council in January. The next annual session will be held at Madison in September. The society was the recipient of a gavel of historical interest presented by the Douglas County Medical Society. It was made from a portion of the keel of the boat *Algonquin* built in 1843, just two years after the establishment of the state society. The boat was the first vessel to sail Lake Superior. The gavel will be used in all future sessions of the house of delegates. The house adopted the recommendation to increase the dues of the society from $10 to $15 a year, to become effective in 1931. One third of all members of the society were in attendance at this session.

Society News.—The thirtieth annual meeting of the Tenth District Medical Society was addressed at Eau Claire, September 30, among others, by Drs. Louis E.
and Francis D. Murphy, Milwaukee, on
and Their Treatment" and "Diabetes: It
Its Management," respectively.——"A *Differential Diagnosis* of Ulcerative Conditions of the Face" was the subject of Dr. Edward Allen Oliver, Chicago, before the Medical Society of Milwaukee County, October 10, and "Significance of Pruritus in Medicine" that of Dr. Francis Eugene Senear, Chicago.——The Barron-Polk-Washburn-Sawyer-Burnett County Medical Society was addressed, September 5, by Dr. Arthur S. Hamilton, Minneapolis, on "Pain and Its Interpretation."——Dr. Chester M. Kurtz, *Madison, spoke on "Diagnosis of Heart* Disease from the Standpoint of the General Practitioner," and Dr. Phillips F. Greene, Madison, "Chinese Medicine" before the *Trempealeau-Jackson-Buffalo* County Medical Society, August 28.——The fall meeting of the Wisconsin Urological Society will be held at Madison, November 21; among the speakers will be Drs. Harry B. Culver, Chicago, whose subject will be "Management of Posterior Urethritis and Some of Its Complications"; Vincent J. O'Conor, Chicago, "Unilateral Hydronephrosis," and Hermon C. Bumpus, Jr., Rochester, Minn., "Uroselectan."

GENERAL

Institute for Radiological Research.—Announcement has been made of the recent formation of the Radiological Research Institute with Dr. Edwin C. Ernst, St. Louis, as president and Dr. Rollin H. Stevens, Detroit, secretary. This is a philanthropic organization whose object is to direct and coordinate research and to collect and disseminate knowledge in radiology gained as a result of purely scientific experiments *or of* experience in practical medicine which results have proved to be of the greatest value in medical practice, the arts and in industry. It *aims also to render financial aid to research, to aid in the* production of radium in this country with an *effort to lower* its cost, and to place newly developed apparatus where it will render the greatest service to humanity. The institute will fully cooperate with existing organizations interested in research pertaining to the study, diagnosis and treatment of diseases, especially cancer. In accordance with its provisions for fellowships in radiologic research, three fellowships have been established for research on roentgen apparatus.

Society News.—The next annual meeting of the Federation of American Societies for Experimental Biology will be held in Montreal, April 8-11, 1931; the secretary is Howard B. Lewis, Ph.D., University of Michigan Medical School, Ann Arbor. ——Dr. Frederick J. Taussig, St. Louis, was elected president of the Central Association of Obstetricians and Gynecologists at the annual session in Excelsior Springs, October 13, succeeding Dr. Palmer Findley, Omaha, the first president of the organization.——The annual meeting of the Western Surgical Association will be held at Kansas City, Mo., December 5-6, with headquarters at the Hotel Muehlebach; the secretary is Dr. Frank R. Teachenor, 306 East Twelfth Street, Kansas City.——At the annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons recently, Dr. Arthur H. Bill, Cleveland, was elected president, and Dr. Magnus A. Tate, Cincinnati, secretary. The next annual session will be held at White Sulphur Springs, W. Va., in September.——The next annual meeting of the Society of American Bacteriologists will be held at Boston, December 29-31; the secretary is J. M. Sherman, Ph.D., Cornell University, Ithaca, N. Y.——The twenty-seventh annual meeting of the American Association of Railway Surgeons will be held in Chicago, November 5-7, with headquarters at the Hotel Sherman. The program will include a symposium on head injuries.

Sickness Among Wage Earners.—Dean K. Brundage of the U. S. Public Health Service, working for the division of research of the Milbank Memorial Fund, recently found that workers in industry are healthier than the general population of the United States. His investigations to ascertain the extent of the disabling sickness among wage earning adults were based on industrial morbidity data covering several years and showed that in manufacturing industries in the country as a whole about 80 per cent of the men are below the age of 45. A larger proportion of the female industrial workers, about 90 to 95 per cent, is below the age of 45. He found that between the ages of 15 and 20 the age curve of illness in a general population group mounts more rapidly than in a typical industrial group. In the general population the trend is steadily upward from the ages of 20 to 24, but among industrial employees the frequency rates rose slowly from the ages of 25 to 40 and then declined at the age of 60, followed by a resumption of the upward trend. During eight years between 1921 and 1928, inclusive, respiratory diseases caused one half of all disabling sicknesses; digestive disorders were second. Contagious and infectious diseases caused about 3 per cent of the cases. Women, especially those married, tended to be absent on account of illness from 50 to 100 per cent more often than men, especially for short periods. Excessive use of alcoholic stimulants was most pronounced among men doing the heaviest and most disagreeable work. An excess in the number of influenza victims was noted among miners and employees of dusty trades, and the incidence of pneumonia was marked among employees of metal industries.

The Poliomyelitis Situation.—Epidemic poliomyelitis shows an upward rise in incidence for the country as a whole. Five hundred and ninety-four cases were reported for the week ended September 27, which represents an increase of *100 over the preceding week, according to Science News Letter.* Normally the seasonal increase would have reached its peak by the middle of October and additional reports should begin to show a decline in the number of cases. There are now more cases in the country than there have been for the last three years. The last large outbreak was in 1927 when at the peak 800 cases were reported and in the great epidemic of 1916 cases were reported by the thousands. In California, poliomyelitis showed a slight temporary rise after a recession in incidence. September 27, the disease was half as prevalent as in July. Increasing prevalence of the disease was noted in New York, Ohio, Kansas and other states, and in some communities drastic measures were inaugurated to curb the epidemic. Detroit has less than half the cases reported between January 1 and October 4, as compared with 1929, when there were seventy-eight cases. During September, officers of the Kansas Health Department made special efforts to check the rising incidence of poliomyelitis, especially in counties served by highways U. S. number 54 and U. S. number 81, where the disease seems to have centered. Newspaper reports showed an increase in prevalence of the disease during September in Minnesota, especially in twenty-three counties in the southwestern part of the state. Minnesota reported 205 cases and nine deaths over a six months' period. The state board of health has asked for an appropriation of $6,487.50 to aid in combating the disease. Ohio reported 100 cases recently. Other high figures were New York, 65; Illinois, 43; Massachusetts, 32; Maine, 21; Iowa, 21; Nebraska, 26; Wisconsin, 20, and Missouri, 18.

Foreign Letters

LONDON

(*From Our Regular Correspondent*)

Oct. 4, 1930.

Early Treatment of Mental Disease

The board of control of the lunacy administration in its report points out that the event of the year was the passage of the mental treatment bill, which enables preventive treatment of incipient mental illness to be carried out by providing outpatient clinics for voluntary treatment, a great departure from the previous official practice, of certifying and confining in asylums persons who were sufficiently demented to be a nuisance or a danger. The treatment of mental illness is assimilated to that of other forms of illness by provisions under which certain cases may be temporarily placed under treatment in institutions without certification and by the opportunities afforded of associating the general hospitals in the treatment of mental illness. The board expresses the hope that local authorities will realize that, from the point of view of humanity and economy, treatment cannot begin too early, and will see that any charge made for the reception of voluntary patients shall not be such as to discourage admissions in the incipient stage. Attention is drawn to the important provision in the act for the temporary treatment of nonvolitional patients on the recommendation of two physicians without the intervention of any judicial authority. The object is to enable incipient mental cases to receive treatment without the stigma of certification. Treatment under this provision is limited to a maximum of six months, subject to permission from the board to extend it, if early recovery appears probable. Another change of great importance is the statutory recognition of the outpatient clinic. Local authorities are now empowered to provide such clinics or to arrange for their provision with the voluntary hospitals. The outpatient clinic is considered the most effective means of bringing within the reach of skilled treatment persons in the earliest stages of mental instability. When a clinic is established at a local hospital it is recommended that the medical staff of the local authority's mental hospital should be associated with the staff of the hospital in the work of the clinic. Local authorities are empowered to make provision for the after-care of patients who have undergone treatment and to contribute to the funds of voluntary associations formed for the purpose. An attempt is made in the act to remedy a great grievance of physicians who sign lunacy certificates—the worry and expense of having actions brought against them by litigious persons on regaining sufficient sanity to be discharged from an asylum. This danger is so great that many physicians decline to have anything to do with lunacy certification. The act provides that persons doing anything under it shall not be liable to legal proceedings if they have acted in good faith and with reasonable care, and the onus of proving the contrary will be on the plaintiff, who must obtain leave from a court to proceed with an action. This will not be given unless the court is satisfied that there is substantial ground for alleging that the defendant acted in bad faith or without reasonable care. A significant change in terminology has been made. It is provided that the term "mental hospital" may be substituted for "asylum" in all official documents. The number of persons of unsound mind under all forms of care increased during the year by 1,307, as compared with an average increase of 2,167 for the last five years. The total number of cases in England and Wales was 142,387, or nearly 3.6 per thousand of population.

Proposed Medical Socialist Organization

In The Journal, August 16, page 543, it was explained that the British Medical Association had brought forward a scheme for a great extension of the form of medical socialism, known as national health insurance, not because either it or the medical profession desired this but because in the present socialistic phase of British politics they feared something worse—a state medical service. In both cases the state would provide a medical treatment for all, but, under the scheme of the association, physicians would continue to work under a contract and the profession would retain some autonomy. Under a state medical service they would simply be civil servants. In the medical profession there is a small body of socialists who desire such a service, and there is no doubt that the present socialist government would be pleased to introduce it if its hands were not so full of other problems. At the National Labor Club a meeting has been held to discuss the formation of a medical socialist organization. Dr. C. W. Brook, the convener, said that he had received a letter from Dr. Ewald Fabian of Berlin, stating that an international union of socialist physicians was about to be created. Dr. Brook advocated the formation of a medical socialist body on the following grounds: (1) as a means of pressing for the establishment of a properly organized national service, (2) as a means of contact through the International Union of Socialist Physicians with other national organizations, (3) as a means of devising legislation for the benefit of the health of the workers and of bringing pressure to bear on the authorities to carry it out, (4) as a means of propagating socialism in the medical profession (he would admit students as associates and so carry the campaign into the medical schools), and (5) as a means of working as an organized body of socialists within medicopolitical organizations. In the discussion that followed, Dr. Menon promised the support of Indian physicians in this country. The following resolution was passed unanimously: "That the members of the medical profession whose political views are in agreement with those of the labor party and with the ideals of socialism be organized as a political body and that a committee be formed to draw up a constitution."

Medical Tests for Automobile Drivers

Since the road traffic act was passed (The Journal, September 6, p. 738) the minister of transport and his officials have been busy with the necessary arrangements for bringing the various sections into operation. Many conferences have been held with automobile associations, manufacturers, insurance companies and trade unions representing members employed on road transport and bodies representing pedestrians. For the licensing of drivers there will be only one standard in all parts of the country. There will be two absolute bars to the granting of a driving license, even if the applicant already holds one. These are extremely defective eyesight and liability to disabling fits. Discussions are proceeding with the British Medical Association and with automobile organizations as to a scientific eyesight test. The broad principle to be adopted is the ability of the applicant to read the ordinary numbers of an automobile at a distance of 30 or 35 yards. Applicants will be required to state on their application forms that, so far as they know, they suffer from no complaint, such as heart attacks, epileptic fits or mental disease, which would interfere with their efficiency as drivers. If the applicant has any doubt he will be expected to take professional advice, as he will be liable to severe penalties for not disclosing essential facts. The disabled man presents some difficulty. If he already holds a license, it will be renewed if he declares that his driving has not been a source of danger to the public. A new applicant will be required to pass a driving test, of which details have been approved by representatives of automobile bodies and of the Disabled Men's Association. Applicants will also be required to produce a certificate that they are covered against third-party risks of death or bodily injury, and this certificate must be carried at all times.

Neuritis in Drivers of Automobiles

During recent years, cervicobrachial neuritis has become a common manifestation in drivers of automobiles. It attacks almost exclusively those who drive closed cars and leave open constantly the window next to them; that is to say, it develops on the left side if the driver is seated to the left or on the right side if the steering wheel is located at the right. Left-drive cars are more numerous in France, since vehicles must keep to the right of the road, so that it is the left hand that is thrust out of the window in order to signal to the cars following that one intends to turn or to stop. The current of air that comes from the side, striking the shoulder and encircling the neck, causes, more especially on cold, damp days, the onset of the condition. The disorder is not found in drivers of open cars. It is a radicular neuritis of the brachial plexus, caused by an arthritis that has its seat at the level of the last cervical articulations, usually the fifth or the sixth. Pressure applied in that region will easily discover the painful spot. At this level, the periarticular swelling exerts a pressure on the medullary roots of the plexus. The pain has its seat in the shoulder and radiates toward the neck and the back. The circumflex nerve is most frequently affected, with the result that pains are provoked in the deltoid muscle and the brachial triceps. The pain is elicited by the movements that bring these muscles into action. But there are also spontaneous paroxysmal attacks lasting for several minutes, which come on in the evening, or at night especially, seriously disturbing sleep. The pains are exacerbated by cold and damp weather. This disorder attacks chiefly rheumatic subjects, and affects the elderly and aged more than it does young persons. Dr. Rathelot of Montpellier, who has published a monograph on this disease, refers to it quite aptly as "sciatica of the arm." The condition presents a similarity to sciatica. It is interesting to note also that, while in sciatica, in accordance with the Lasègue sign, an acute pain is elicited when the patient, while lying on his back, raises the leg, with the thigh flexed, toward the abdomen, a similar pain is provoked when the arm is extended horizontally and backward and the forearm is raised in supination, which brings about an elongation of the plexus. It is a condition that is not so easy to get rid of. Diathermy and infra-red rays have been employed without great success. Massage of the vertebrae is rather dangerous unless it is carried out with great prudence. The best treatment is exposure of the region to roentgen rays for ten minutes, twice a week, in small doses, for at least a month. Success has attended also local applications of radium, spread about in containers, for several days in succession.

Enlargement of the Radium Institute

Belgium radium continues to be sold at a high price, in spite of the competition offered by Russian radium; hence a large parcel of ground has been placed at the disposal of Madame Curie for the erection of a factory for the manufacture of radium. At the same time the Institut du radium, of which she is the codirector along with Professor Regaud, having outgrown its small quarters by reason of the afflux of patients, is to be enlarged, the city of Paris having placed at her disposal a large plot of ground contiguous to the institute, on which research laboratories and a hospital for the application of radium treatment will be built.

Trypanosomiasis in Kamerun

Severe criticism has been raised in Germany against the sanitary organization of Kamerun since, after the war, it ceased to be a protectorate of Germany and became a protectorate of France. It has been asserted that, while under German control, there were only 6,000 cases of trypanosomiasis in the country and that now there are 315,000 cases. An article published by the colonial minister tones down these exaggerations. There are at present 115,000 cases. The Germans, however, had only two or three physicians prospecting in a fractional part of the country. There are at present eleven physicians, aided by native men nurses, with the result that they have explored the whole country and made an exact enumeration of cases. Isolation camps have been created where groups of patients are assembled and subjected to intensive treatment. It is thought that, within three years, the disease will have totally disappeared from the country, since the Belgians are carrying on the same intensive crusade in the neighboring Congo region.

Professor Censured for Advertising

The council of the syndicate of the physicians of the Seine (region of Paris) recently reached three decisions that it has made public through the press. The action of the council is without precedent and appears likely to create dissension in the medical profession. The syndicate is possibly within its rights in watching over the good name of the medical profession and in censuring confrères who have committed a tort against the rules of the profession; but heretofore it has never given public notice of the events. The first vote of censure expresses disapproval of the conduct of certain physicians occupying official positions at the Faculté de médecine and on the staffs of the hôpitaux de Paris, who, in public lectures and in the newspapers, took part in a controversy on the subject of the division of fees between the surgeon and the physician who refers patients to him. The resolution says: "These are matters that may be censurable or not, depending on the circumstances. The public is not to be the judge, and if misinformed, the public may get impressions that reflect on the credit of the whole profession." The second resolution censures physicians occupying an official position—professors, for example—who allow their names to be employed by a commercial house in order to promote the sales of a pharmaceutic specialty. It is evident that a certain professor is meant who, after publishing his articles on the use of magnesium chloride as a preventive of cancer and as a means of retarding the approach of old age, is said to have allowed his name to be used to promote the sales of a certain brand of magnesium chloride tablets. The third resolution is aimed against physicians who, in a recent edition of the official telephone directory, have had their names printed in display type, followed by statements as to the various diseases that they assert they are able to cure, in order to attract the attention of the public. For this privilege they pay, of course, an additional sum, so that it is, in reality, nothing other than a commercial advertisement. The council of the syndicate of physicians regards such procedures as reflections on the dignity of the profession and felt it was its duty to express its condemnation. It is the general opinion, however, that, while the censure may be justified, it would have been better if it had been expressed at a meeting of the council on medical ethics and not communicated to the public.

Houses of Prostitution Closed in Strasbourg

For many years there have existed in France houses termed "maisons de tolérance," occupied by prostitutes, who are subjected to periodic examinations. Two opposing groups of citizens have likewise existed for years, one of which argued for the regrettable but undoubted necessity of such places, in order to limit, by means of supervision, the propagation of venereal disease; the other group demanded that such places be suppressed in the name of morality and out of respect for the dignity of women, and for the reason that their effect on venereal prophylaxis is nil. In recent years an experiment has been tried in Strasbourg, where, in pursuance of a prefectural decree, such houses have been closed since Jan. 1, 1926. An endeavor has been made to discover whether, as a result of this closing measure, the cases of venereal disease in Strasbourg have increased or diminished. Statistics have been collected but their showings were interpreted so diversely that an official commission composed of Dr. Lévy-Bing, physician on the staff of the department for venereal women of the Infirmerie de la prison St. Lazare in Paris, Dr. Cavaillon, head of the prophylaxis service of the ministry of public health, and Madame Avril de Ste. Croix, president of the Conseil national des femmes françaises, was appointed to make an inquiry on the subject. The commission reached the following conclusions: The first two years that followed the closing of the "maisons de tolérance" in Strasbourg were followed by a marked increase of syphilis in that city. It is true, however, that these houses were nearly all transformed into saloons, or beer-shops, where prostitution, which had been open and supervised medically, became clandestine and unsupervised. During the next two years, however, there was a notable decrease in venereal disease, as confirmed by hospital reports and by the infirmaries at the garrisons. No exact statements can be made with reference to the cases cared for by the physicians in their private offices. The commission concluded that the closing of the "maisons de tolérance" has had no recognizable influence on the status of venereal disease in Strasbourg, and that the decline in the number of cases is more likely due to the greater intensity with which, of late, the antivenereal crusade has been waged.

Self-Destruction in Twenty Years in Spain

Dr. Miguel España has prepared statistics on suicide in Spain in the period from 1907 to 1927. The rate in 1927 was 100 per million of population, which gives a total figure of 2,300 suicides for the year. During the twenty years, the number of suicides has been continually increasing. In 1907 the annual rate was 69 per million people and 1,050 men and 335 women did or attempted to commit suicide. In 1927 the suicides comprised 1,515 men and 528 women. The number of suicides committed during the twenty years was 31,261 (23,908 men and 7,353 women). The number of attempted suicides during the same period was 6,001 (3,632 men and 2,369 women). Among the men who killed themselves in 1907 there were 466 bachelors, 598 married men and 213 widowers. In 1927 the figures were 474 bachelors, 733 married men and 725 widowers. In the last year the number among married men and widowers was about the same. The month in which the fewest suicides occur is November; the month in which the largest number is committed is June. The method employed was as follows: firearms, 8,683 men and 509 women; swords and other cutting weapons, 2,110 men and 411 women; drowning, 3,904 men and 2,746 women; poisoning, 998 men and 2,177 women; hanging, 7,259 men and 2,012 women; asphyxia, 278 men and 116 women; leaping, 1,976 men and 1,282 women; by trains, 1,847 men and 347 women. The causes were: illness, 9,933 men and 4,000 women; disappointment, 2,122 men and 283 women; misfortune, 1,330 men and 94 women; misery, 871 men and 238 women; dismissal from positions, 171 men and 18 women; domestic troubles, 1,147 men and 832 women; love, 754 men and 703 women; jealousy, 128 men and 56 women; honor, 98 men and 119 women.

Intercontinental Transmission of Heart Sounds by Telephone

The Telephone Company of Spain gave recently a scientific demonstration to a group of physicians, consisting in the transmission of sounds of the heart and lungs of normal persons and patients with diseases of the heart and respiratory tract from Buenos Aires to Spain. The sounds were transmitted first by radio and then by telephone, so clearly that Spanish physicians who attended the demonstration were able to make a diagnosis in Spain at the same time that it was made at Buenos Aires by Argentine physicians who were actually present with the patient. Then a discussion between Dr. Montellano, who was at Buenos Aires at the bedside of the patients, and the Argentine physicians followed the demonstration, and this was also transmitted by telephone. The diagnosis made by the Argentine physicians agreed with that made by the Spanish physicians. The demonstrations will be repeated, and physicians who wish to attend will be inscribed in a list, which at Madrid alone numbers more than 850.

Epilepsy

At the Academia Médico Quirúrgica of Madrid, Dr. Sanchiz Banus read a paper on epilepsy in which he said the disease is more common in men than in women, and that as a rule epileptic mothers transmit the disease to their male children while epileptic fathers transmit it to their female children. Headache in the patient or in near relatives has a relation to epilepsy. The speaker observed this symptom in 54 per cent of epileptic patients, in 64 per cent of mothers, in 8 per cent of fathers and in 24 per cent of near relatives of persons with epilepsy. The following familial characteristics were observed: an exaggerated feeling of mysticism in 24 per cent of the cases and pathologic irritability in 36 per cent of the cases. The speaker considered some accidents of a mechanical type during labor as a relatively frequent factor in the etiology of epilepsy.

Dr. Lopez Aydillo spoke on epileptic equivalents (headache, impulses, nocturnal enuresis, left-handedness, somnambulism, night terrors, dipsomania and narcolepsy) which he observed in 250 patients with typical epilepsy. Epileptic parents may transmit to their children either the disease itself or epileptic equivalents; parents who have epileptic equivalents may transmit either the epileptic equivalents which they have, or the disease itself which in them was not entirely developed, since both epilepsy and epileptic equivalents are originated from the same epileptic genotype.

Dr. Vallejo Nájera spoke on the medical treatment of epilepsy. Since the pathogenesis of the convulsions is unknown, the mechanism by which effective antiepileptic remedies control the crisis cannot be determined. Phenobarbital is the remedy that yields the best results against epilepsy, and next in importance is combined treatment with bromides and borates. A combined treatment of calcium and parathyroid extract reestablishes the calcium equilibrium of the blood. The results with the ketogenic diet are fair, but it offers difficulties which can be overcome only in infants.

Dr. Villaverde spoke on the surgical treatment of epilepsy. Lesions of the cornu ammonis, disappearance of myelin and atrophy of the brain convolutions have been observed in epilepsy. The speaker believes that the removal of the suprarenal glands and the resection of the superior cervical sympathetic ganglion of epileptic patients do not give satisfactory results. Trepanation, when used, should be made according to Kocher's method. Generally there is a pessimistic feeling against the few resources offered by surgery in the treatment of epilepsy.

False Diagnosis of Syphilis

At a meeting of the Academia Médico Quirúrgica of Madrid, Dr. Gay stated that in 7 per cent of the cases diagnosed as syphilis the diagnosis is wrong. The penal code of Spain imposes punishments for wrong diagnosis made on several conditions, but especially for the wrong diagnosis of syphilis. The speaker believes that the diagnosis of syphilis should be made on the basis of ultramicroscopic examinations of the lesions. Dr. Bejarano said that the average physician criticizes syphilologists because they seem to make a diagnosis of syphilis more frequently than the disease really is present. The speaker agrees that the diagnosis of syphilis should be based on ultramicroscopic observations of the lesions and not on the clinical symptoms presented by the patient. A weakly positive serologic reaction is not by itself an indication for antisyphilitic treatment. Dr. Covisa said that no antisyphilitic treatment should be given on the assumption of syphilis until the diagnosis of the disease is proved by the ultramicroscopic examination of the lesions, if the patient is in the first period of syphilis, or of a complete serologic examination if the patient is in the more advanced periods of the disease.

Serotherapy in Poliomyelitis

Dr. M. Bonavente recently presented a paper on poliomyelitis based on studies made at the Hospital del Niño Jesús during the last epidemic of poliomyelitis in Madrid. The author made the following conclusions: In the preparation of stock serums, careful asepsis is necessary. The activity of serums is in relation to their biochemical modifications. Serums reach their peak of activity in three or four months after their preparation. The author compared results obtained in poliomyelitis with the serum of convalescents and those obtained with serum of normal persons or antidiphtheritic serum and also with the cases in which no serotherapy was given. Patients treated with convalescent serum had a regression more rapid than those treated with other types of serum or those to whom no serum was given. Serum of convalescents should be given early in poliomyelitis to avoid spinal cord congestion and paralysis.

BERLIN

Sept. 29, 1930.

The Annual Meeting of German Scientists and Physicians

The Gesellschaft deutscher Naturforscher und Aerzte held its annual session in Königsberg, October 7-10. In his address of welcome, the Prussian *ministerpräsident,* Dr. Braun, said: "It is my heartfelt desire that your session may receive widespread attention in these days of political stress in our fatherland, far beyond the circles interested in pure science. It must be admitted that the quiet work of the scientific investigator is not yet appreciated in our country as it should be. The worship and glorification of the mailed fist observed today among our people constitute a sad and serious sign of mental aberration." It was pleasing to hear his enthusiastic words with reference to the heroism and the true leadership of the great scientific investigators who are working to promote the public health and to extend the bounds of knowledge, thereby setting goals for the oncoming generations to strive to reach and surpass.

The transactions gave an insight into many branches of scientific medicine; into the progress that is being made in all fields, and into the chief questions that, at present, occupy the minds of research workers and practitioners.

From the philosophic standpoint, the most important address was that of Prof. David Hilbert, mathematician, of Göttingen, who took as his subject "Naturkenntnis und Logik." According to Hilbert's conception of mathematics, it exerts an important influence on our view of the world and it may, in a sense, be said to constitute a world view in itself. The results of this exact science, which serves as an instrument of mediation between theory and practice and between thinking and observing, justify, he thinks, the declaration: "Instead of 'We cannot know,' our watchword must be: *we must know and we will know.*"

The second address was a memorial to Lothar Meyer. F. Paneth, chemist, of Königsberg, explained the development and the present status of our knowledge of the elements of the physical universe; the progress made in the study of the electrons, and the Rutherford-Bohr theory of electrically charged atoms. Since the research of Moseley, who fell in the battle of the Dardanelles, in 1915, not yet 28 years of age, we know that the positively charged nucleus constitutes the basis of the system of the elements and not, as Lothar Meyer and Mendelyeev had assumed, the atomic weight.

In the medical section, Hans Fischer, chemist, of Munich, who is also a physician, gave a comprehensive insight into the chemical connections between hemin, bilirubin and the porphyrins, adding many interesting physiologic and clinical observations. Some important connections with one of the greatest problems of organic chemistry were presented by the speaker and considerable light was thrown on them. These statements were supplemented by an address by Borst, pathologist, of Munich: "Morphologic Aspects of the Porphyrins." It became evident that his observations coincided closely with those of Fischer. Poppe of Rostock followed with a paper on "The Etiology, Pathogenesis and Experimental Diagnosis of Infection with Bacillus of Bang." W. Stepp, internist, of Breslau, gave an excellent clinical survey of this disease, which is at present in the forefront of medical interest. The most effective method of treatment consists in injections of increasing doses of killed Bang bacilli, which may now be procured in the open market.

The second general session was opened by Heinroth, zoologist, of Berlin, director of the Berlin Aquarium and the Rossitten ornithologic exhibit (Vogelwarte), who spoke on "Development of Early Bodily and Mental Characteristics in Domestic Birds."

Professor Bumke of Munich discussed with eloquence the topic of psychoanalysis. It is a natural corollary of the historical development of the theory of psychoanalysis, and also of its content, that the attitude of the individual investigator toward it must always be a subjective attitude. For almost thirty years, Bumke has been an opponent of this movement. While he recognizes the preeminent mental qualities of Freud, he rejects absolutely his teachings. But still more than the content of Freud's teachings, he opposes the methods on which Freud bases his teachings, because, in his opinion, they are not compatible with the principles of exact scientific research, since they cannot be checked up or substantiated by other investigators. After Bumke had described, in a few words, the attitude of various scientific investigators to Freud's theory, he mentioned the views of Thomas Mann, who has declared Freud's libido theory to be natural science in the form of romanticism and describes it as a manifestation of modern irrationalism. "Did Thomas Mann misunderstand Freud; do the rest of us who oppose him fail to comprehend him, or is (which appears more likely) psychoanalysis itself full of contradictions?" Charles Maylan, an adherent of psychoanalysis, thinks Freud has been misunderstood. According to Maylan, psychoanalysis was an outgrowth of Freud's resentment. His hatred of his *father and of the pope,* who is identified with the father and who, at the same time, is the head of christendom, and his dissatisfaction with scientific leaders, who withheld from him so long just recognition—all these feelings have tinged Freud's pen. One need not accept Maylan's interpretation, and one may even regret, for reasons affecting humanity in general, that the book was ever written. But one must admit that psychoanalysis did not come into being in the manner that its adherents maintain—by the application of an exact scientific method; by the establishment of incontrovertible facts and by a clear and intelligent study of such facts. Freud can perhaps be called, in one sense, a romanticist, because he does not derive his views from an application of his method but has had to adapt his method to fit his opinions. Freud's appearance on the horizon can best be understood by considering somewhat closely the period in which he began his work.

In the tenth decade of last century, there arose on the horizon two men, each appearing to possess the qualifications necessary for the creation of a new psychology: Dilthey and Freud. Dilthey was soon forgotten by the psychologists. Freud, with pronounced aptitude for psychology, has an artistic insight into the profound and obscure relationships of the psyche. He is fettered, however, by a materialistic attitude of mind. When he takes up scientific work, he has first to translate everything that is psychic into its biologic counterpart; he appears compelled to view his subject dynamically, from the standpoint of energy, and to talk about natural science when he really has in mind psychic relationships. When he comes in contact with the irrational or the subconscious, it has to be promptly rationalized and mechanized, and hypotheses are set up that may be regarded as irrational or, with equal correctness, as rudely materialistic. The subconscious with Freud is a subpsyche that *elaborates the superconscious material supplied by the emotions and the intellect, but without furnishing the superconscious realm anything other than completed ideas.* Bumke came to speak of Freud's interpretations—of the sexual substratum by and through which everything in the subconscious is regulated. He brought up interpretations of dreams as given by Freud, which are so schematized that one is reminded of translations made with the aid of a precise glossary. The real ego, which thinks and feels, desires, hates and loves, and which, above all, is "always sexually charged," not only deceives others but deludes and misleads constantly its own superconsciousness. The whole thing is assuredly a myth—not irrational, however, but puzzled out with all manner of subtlety and elaborated with all the devices of the dialectic art. A doctrine that constantly confuses possible with established facts, that does not distinguish between facts and interpretations, is not only not entitled to be classed under the natural sciences but is not entitled to be regarded as belonging to "science" at all. It lacks spontaneity because it comes from a cold and erratic intellect given over to gloomy speculation. A subconscious mind such as Freud describes—which thinks and feels—such a complicated subpsyche has never been shown to exist. There is, to be sure, a subconscious area, something that we do not wish to know and therefore thrust aside so far as possible. The double nature of the psyche has been recognized by poets. Faust has in Mephistopheles one who plays "opposite" to him; but Faust no longer needs Mephistopheles after his soul becomes purified. Were it not for this dualism of the soul there would be no particular merit, Bumke points out, for one to conduct himself fairly decently. As for the future of the freudian doctrine, Bumke ventures the opinion that the method will fall into desuetude because, in reality, it proves nothing and constantly distorts facts to fit its hypotheses. But certain perceptions, which are the products of the psychologic talent of their creator, will remain. The fundamental insight that the final goal of all psychology must be to comprehend man as a whole appears likely to be a permanent acquisition. Bumke's presentation was a rousing critical appeal, as *Aschoff justly emphasized in his words of appreciation* addressed to the author, and will cause every one to consider anew his attitude toward freudism.

The third speaker was Professor Teutschlaender of Heidelberg, who discussed "Cancer as a Disease Common to the Whole German People." About every tenth German who dies after the age of 40 dies from cancer. As in other countries, the mortality from cancer is increasing also in Germany, and it threatens to exceed that of tuberculosis. It is estimated that the annual number of cases in Germany ranges from 100,000 to 200,000 cases. The prevention of cancer is of the greatest importance. In the formation of cancer three factors of equal importance are involved: (1) an irritant acting on proliferative cells and set up by a factor acting from without or originating within the organism—the causative agent; (2) the predisposition, local or general disposition of the organism, which enables it to respond to the irritation set up by the causative agent with a cancer formation, and (3) in case the disposition is not yet fully developed, sufficient exposure; that is, the opportunity for sufficiently long action of the irritant. These three factors may vary as to their respective potencies, and particularly, one factor may be highly developed while the others are but weakly operative. Thus, cancer formation may sometimes be the expression of an acquired or inherited constitution, or it may be conditioned by certain environmental factors or the subject's mode of living. The decisive specific factor does not attack from without; it lies or develops within the organism itself; it is endogenous. As there is virtually no contagion through cancer patients and also heredity plays no considerable rôle in man, the most important factor with reference to cancer disease as affecting the masses of the people is the nature of our present modern civilization, which, owing to the departures from nature in customs and habits of living and the ever increasing industrialization, brings about an enhancement of the three factors that play the chief part in the etiology of cancer. Evidence for the effects of our form of civilization on the spread of cancer is furnished, on the one hand, by the increased influence of a considerable number of etiologic factors, and, on the other hand, by the fact that today, to an ever increasing extent, cancers are diagnosed that owe their origin solely to the cultural trends and therefore may reasonably be termed "the cancers of modern civilization." The tar and dye industry, which dates its origin back less than a century, is putting daily on the market new products, some of which possess cancer-producing properties. The industry affords a wide field for the action of these products and, in fact, it arranges the tables for a veritable nation-wide experiment through industrial exposure, which, in turn, brings about a premature predisposition such as would not be acquired physiologically until a much later age is reached. The unsuitable diet of civilized nations may, on the one hand, through direct irritation of the mucosae of the digestive tract, and, secondly, by way of intoxications and disturbances of metabolism, exert a predisposing effect. In addition to the increasing number of occupational cancers, the cancers that develop from the habitual ingestion of arsenic may be regarded as cancers intimately associated with the nature of modern civilization. While it is doubtless true that many cancers are causally conditioned by our peculiar type of civilization, it would be wrong to consider all forms of cancer as the result of such influence. However, the increase in cancer is not a necessary accompaniment of civilized life as we know it, since we can already prevent occupational cancers and certain other cancerous formations not associated with our type of civilization. By destroying the evil effects of cancer-producing noxae—possibly also by bringing an influence to bear on constitutional factors—the spread of cancer must be combated, and already much has been accomplished in this direction by industrial hygiene. However, it will not be possible to eradicate cancer entirely with the sole application of hygienic measures. But with the aid of prophylactic measures, education, early treatment and the elimination of manifestations known as preconditions of cancer, which often cause patients little discomfort at the time, it must prove possible to reduce the number of cancer patients. It is better, and, as it seems, much easier, to prevent cancer than to cure it.

In addition, there were many special sessions on single subjects and combined subjects; thus, on radium surgery, roentgenologic diagnosis of the large intestine, benign disorders of the mammary gland and cancer of the breast, the rôle of the nucleus and the plasma in hereditary transmission, the migration of nematode larvae (with an excellent film), the origin of parasitic diseases in general, the eye and radiant energy, thrombosis and embolism, trachoma, social problems, and many other subjects of a similar nature. Professor Askanazy of Geneva explained the nature of the problem of comparative pathology, or a comparison of the pathologic phenomena of various peoples. The scope of the problem includes also the immunity or predisposition of the races with respect to individual diseases: the nature of the landscape as the source of a joyous disposition, of an earnest view of life and of resistance to disease. For general hygiene and for the prevention and cure of individual diseases, comparative pathology may have great value.

Marriages

ROBERT M. THOMAS, Oakland, Calif., to Miss Peggy Amelung of Los Angeles, in Worthington, Ohio, August 23.

JOHN WILLIAM HUFFMAN, Tucson, Ariz., to Miss Florence Kearnes of Evanston, Ill., August 18.

LAURENCE M. MOORE, Benton, Ill., to Miss Hazelle Dean Boland in Topeka, Kan., August 16.

GEORGE B. DORNBLASER, Hazelton, Pa., to Miss Grace Mildred Altmiller, August 12.

HOMER S. MCCOY, Sylvester, Ga., to Miss Eva Mae Bius, August 17.

Deaths

Hartstein Wendell Page, Worcester, Mass.; Medical School of Maine, Portland, 1888; member of the Massachusetts Medical Society, the American Psychiatric Association and the New England Society of Psychiatry; formerly superintendent of the Hospital Cottages for Children, Baldwinsville; aged 73; died, August 29, in York Beach, Me., of coronary thrombosis.

Thomas Benjamin Smiley ⊕ Mount Vernon, S. D.; University of Bishop College Faculty of Medicine, Montreal, Que., Canada, 1893; past president of the South Dakota State Medical Association; delegate to the American Medical Association, 1911-1912; aged 64; died, September 29, of lymphatic leukemia.

Charles Bliss Stockwell, Port Huron, Mich.; Harvard University Medical School, Boston, 1878; member and past president of the Michigan State Medical Society; past president of St. Clair County Medical Society; aged 79; died, October 7, in Montour Falls, N. Y.

Charles E. Chapin ⊕ Bloomington, Ill.; Rush Medical College, Chicago, 1891; past president of the McLean County Medical Society; medical director of the Brokaw Hospital; aged 64; died, September 26, of cerebral hemorrhage.

Adam Young Myers ⊕ Hyndsville, N. Y.; Albany Medical College, 1882; past president of the Medical Society of Troy and Vicinity, and the Schoharie County Medical Society; aged 77; died, October 1, of cardiorenal disease.

Samuel Gayle Deatherage, Sugar Land, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1892; member of the State Medical Association of Texas; aged 59; died, June 5, in Missouri City, of myocarditis.

Samuel G. Worley, St. Augustine, Fla.; Atlanta Medical College, 1882; member of the Florida Medical Association; aged 74; died, in September, in a hospital at Grantville, Ga., of paralysis and hypostatic pneumonia.

John T. Perry ⊕ Tulsa, Okla.; University of Arkansas School of Medicine, Little Rock, 1906; on the staff of the Morningside Hospital; aged 55; died, August 21, of septicemia following an infection on the face.

Norman William Andrews, Battle Creek, Mich.; University of Michigan Medical School, Ann Arbor, 1880; aged 72; died, September 13, in the University Hospital, Ann Arbor, of myocarditis.

McCord G. Roberts, Springfield, Mo.; St. Louis College of Physicians and Surgeons, 1891; member of the Missouri State Medical Association; aged 69; died, August 27, of cerebral hemorrhage.

George Clyde Ruble, Santa Ana, Calif.; University of Oklahoma School of Medicine, Oklahoma City, 1922; member of the California Medical Association; aged 31; died, June 3, of uremia.

Gilbert Haven Galford, Ashland, Wis.; Hahnemann Medical College and Hospital, Chicago, 1908; aged 47; was drowned, September 21, in the Chippewa River, when his boat was capsized.

Bennett Merwin Hines ⊕ Uvalde, Texas; University of Nashville (Tenn.) Medical Department, 1894; city and county health officer; aged 60; died suddenly, August 28, of heart disease.

Clarence Eugene Bulette, Las Vegas, Nev.; Gross Medical College, 1897; aged 62; died, March 25, in the Ferguson Hospital, of chronic nephritis, myocarditis and arteriosclerosis.

Alfred Gideon Kyle, Knoxville, Tenn.; Memphis Hospital Medical College, 1900; member of the Tennessee State Medical Association; aged 60; died, August 30, of cardiorenal disease.

Bret Albert Swartz, Monrovia, Calif.; Medical Department of the University of Southern California, Los Angeles, 1917; aged 40; died, July 24, of pulmonary tuberculosis.

Matt Russell Root ⊕ Denver; Colorado School of Medicine, Denver, 1897; member of the American College of Surgeons; aged 66; died, in September, of heart disease.

Claude A. Avery, Bethalto, Ill.; Barnes Medical College, St. Louis, 1903; member of the Illinois State Medical Society; aged 52; died, September 20, of heart disease.

Kurt L. Elsner, Brooklyn; Universitat Munchen Medizinische Fakultat, Munich, Bavaria, Germany, 1896; aged 57; died suddenly, September 17, of arteriosclerosis.

Frank Edgar Stowell ⊕ Worcester, Mass.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1903; aged 51; died, August 31, of pulmonary tuberculosis.

Alexander Smith Sim ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1904; served during the World War; aged 50; died, September 15, of heart disease.

Clareld Edison Dorland ⊕ Devils Slide, Utah; Northwestern University School of Medicine, Chicago, 1907; aged 50; died, August 19, of cerebral hemorrhage.

William Kennedy Williams, Phoenixville, Pa.; State University of Iowa College of Medicine, Iowa City, 1880; aged 84; died, September 12, of uremia.

Glenn Raymond Ray, Decatur, Ill.; University of Illinois College of Medicine, Chicago, 1929; aged 27; was killed, September 15, in an automobile accident.

Walter Scott Spence ⊕ Hopedale, Ohio; Medical Department of Western Reserve University, Cleveland, 1892; aged 64; died, September 19, of heart disease.

Henry Charles Towle ⊕ Boston; Medical Department of the University of the City of New York, 1877; aged 78; died, September 5, of cerebral hemorrhage.

George O. W. Farnham, Lincoln, Neb.; University of Vermont College of Medicine, Burlington, 1884; died, September 5, of carcinoma of the stomach.

Mark Straus Polak, New York; Eclectic Medical College of the City of New York, 1892; aged 63; died, August 15, of carcinoma of the sigmoid flexure.

John William Shute, Bishop, Calif.; Hahnemann Hospital College of San Francisco, 1900; aged 62; died, July 23, of chronic parenchymatous nephritis.

John Anthon Callender, Oakland, Calif.; Medical Department of Columbia College, New York, 1868; aged 85; died, July 18, of cerebral hemorrhage.

Thomas Harrison Stetler, Pawpaw, Ill.; Chicago Medical College, 1876; aged 83; died, September 27, of uremic poisoning following chronic nephritis.

Griffith William Prees, Cambria, Wis.; Miami Medical College, Cincinnati, 1888; aged 79; died, September 8, of carcinoma of the stomach.

Charles H. Kaetel, Milwaukee; Pulte Medical College, Cincinnati, 1877; aged 80; died, September 6, of senile dementia and arteriosclerosis.

Noah Frederick Schmucker, *Mount Jackson, Va.;* Baltimore Medical College, 1897; aged 58; died, September 14, of diabetes mellitus.

Martin Luther Stiffler, St. Paul; University of Colorado School of Medicine, Denver, 1913; aged 43; died, September 7, of heart disease.

William J. Webb, Danville, Ill.; Columbus (Ohio) Medical College, 1884; aged 71; was found dead in bed, September 24, of heart disease.

John S. Cummins, Rosiclare, Ill.; Medical College of Evansville, Ind., 1883; aged 81; died, in September at Metropole, of arteriosclerosis.

Emmett B. McCormick, Owensboro, Ky.; Hospital College of Medicine, Louisville, 1881; aged 76; died, September 13, of heart disease.

Sefron C. Culpepper, Wiggins, Miss.; Louisville (Ky.) Medical College, 1894; aged 59; died, September 15, of pneumonia.

William S. Gordan, Converse, Ind.; American Medical College, St. Louis, 1890; aged 64; died, August 24, of heart disease.

Fred G. McMitchell, Gary, Ind.; Meharry Medical College, Nashville, Tenn., 1914; aged 50; died, July 30, of heart disease.

J. M. Blair, Monroe, N. C.; Louisville (Ky.) Medical College, 1887; aged 66; died, September 10, of cerebral hemorrhage.

Charles William Baker, Rossville, Tenn. (licensed, Tennessee, 1908); aged 58; died in August.

Bureau of Investigation

MORE MISBRANDED NOSTRUMS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

Michael's Cold Tablets.—The C. P. Products Company, Kokomo, Ind., shipped in December, 1928, into Illinois a quantity of Dr. Michael's Cold Tablets that were declared misbranded. They were found on analysis to be brown-coated tablets containing, essentially, acetanilide, sugar, talc, red pepper and a small amount of the laxative, phenolphthalein. The claims that it was a remedy for influenza, acute catarrh, neuralgia and fevers, and other conditions, were declared false and fraudulent. In April, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16783; issued May, 1930.*]

Mosso's Oil of Salt.—The C. A. Mosso Laboratories of Chicago shipped in May, 1928, and January and April, 1929, a quantity of Mosso's Oil of Salt that was declared adulterated and misbranded. The federal chemists reported that the preparation consisted essentially of linseed oil, oil of turpentine, camphor and phenol, and that "bacteriological examination showed that the product was not antiseptic." The claims that the product would check infection, that it was antiseptic and germicidal, that it was a valuable aid in the treatment of pyorrhea and other diseases of the mouth and gums, that it would check the flow of blood, and that it would do many other things, were declared false and fraudulent. In June, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16778; issued May, 1930.*]

MOSSO'S
OIL-of-SALT
ANTISEPTIC
First Aid to the Injured
C. A. Mosso Laboratories Chicago
FIRST AID TO THE INJURED

[Mosso's Oil of Salt was analyzed in the A. M. A. Chemical Laboratory in 1915 and an article on the subject was prepared by the Bureau of Investigation and published in The Journal, August 14, 1915. The matter is reprinted in the pamphlet "Miscellaneous Nostrums."]

Nozeline. — The Nozeline Laboratory, Long Island City, N. Y., in January, 1929, shipped into New Jersey a quantity of Nozeline that was declared misbranded. Analysis by the federal chemists showed it to consist essentially of mineral oil, containing about 2 per cent of volatile matter, including eucalyptol, oil of pine, menthol and camphor. The claims on the trade package, to the effect that it was a remedy for catarrh, hay fever, throat ailments, nasal affections, etc., were declared false and fraudulent, and in July, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16782; issued May, 1930.*]

Laxacold.—The Nyal Company, Detroit, Mich., in January, 1929, shipped into Illinois a quantity of Laxacold that was declared misbranded. The Laxacold tablets were found to contain acetanilide, alkaloids of aconite and of cinchona, extracts of plant drugs, including podophyllum and jalap, with camphor, red pepper, sulphates, and a small amount of salicylates. The claims on the trade package, that the product would quickly relieve grippe, flu and neuralgia, were declared false and fraudulent, while the statement on the package, that the tablets were safe, was declared false and misleading. In April, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16784; issued May, 1930.*]

Nyal Cold Capsules.—The Nyal Company of Detroit, Mich., shipped in September, 1928, into Illinois a quantity of Nyal Cold Capsules that were declared misbranded. The government chemists reported that the capsules contained acetanilide, chalk, cinchonine sulphate, and small amounts of red pepper, camphor, podophyllin, and the alkaloids of aconite. The claims on the trade package, that these capsules were a remedy for influenza, neuralgia, etc., were declared false and fraudulent, and the statement that the capsules were safe was declared false and misleading. In April, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16785; issued May, 1930.*]

Diemer's Laxative Grip and Cold Tablets.—The Sta-Wel Remedy Company, Springfield, Mo., shipped in November, 1928, into Illinois a quantity of Dr. F. W. Diemer's Laxative Grip and Cold Tablets that were declared misbranded. The tablets were found to contain acetanilide, baking soda, red pepper and some laxative drugs. The claim that the tablets were a remedy for influenza was declared false and fraudulent and in April, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed. —[*Notice of Judgment 16786; issued May, 1930.*]

Reno's Antiseptic Wash.—S. B. Leonardi and Company, New Rochelle, N. Y., shipped in May, 1928, to California a quantity of Reno's Antiseptic Wash that was declared adulterated and misbranded. The stuff was found to consist essentially of water (99 per cent) and small amounts of boric acid, camphor, and a trace of alkaloids. The federal authorities reported: "Bacteriological examination showed that the product was not antiseptic." The product was declared adulterated because it was sold as an antiseptic when it was not, and therefore fell below such professed standard. The claims that it was a remedy for leucorrhea, or "whites," and all discharges due to inflammation of the vaginal mucous membrane, were declared false and fraudulent. In August, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16788; issued May, 1930.*]

Devel's Grippe.—The Devel's Chemical Company, Sylvester, Ga., shipped in January, 1929, into Florida a quantity of Devel's Grippe, which was declared misbranded. Analysis showed the product to consist essentially of extracts of plant drugs, including licorice and a laxative plant drug, with saccharine and volatile oils, including oil of anise, in a solution of alcohol and water. The claims that the product was a remedy for influenza, cough, fever, bronchitis, lumbago, neuralgia, and various other conditions, were declared false and fraudulent, and in September, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16789; issued May, 1930.*]

Dionol.—The Dionol Company, Detroit, Mich., shipped into the District of Columbia in January, 1929, a quantity of Dionol that was declared misbranded. Government chemists reported that analysis showed the product to consist of white petrolatum! The curative claims for the preparation in such conditions as hemorrhoids, throat and lung diseases, infected wounds, pelvic congestion, etc., were declared false and fraudulent, and in August, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16794; issued May, 1930.*]

[Dionol was the subject of brief reports in this department of The Journal, Jan. 26, 1918, and Feb. 7, 1920. The product was there declared to be a glorified and esoteric form of petrolatum.]

Correspondence

PRIORITY IN TREATMENT METHOD OF BROMIDE INTOXICATION

To the Editor:—In The Journal, July 12, Harris and Hauser published their paper on "Bromide Intoxication," in which success therapeutically depended on the replacement of bromine ions by chlorine ions; in this connection may I direct credit for originality where, I believe, credit is due.

The principle that the excretion of chlorides could be hastened by the administration of bromides and iodides, and that, conversely, the administration of chlorides hastens the elimination of the other two, was developed as far back as 1902 and 1911 (Sollmann: Manual of Pharmacology). Credit for the application of this biologic fact to therapeutics belongs, however, to the dermatologists Wile, Wright and Smith (*Arch. Dermat. & Syph.* **6**:529 [Nov.] 1922). A second report by Wile (*Arch. Dermat. & Syph.* **8**:407 [Sept.] 1923) in 1923 included the treatment of bromide intoxication as well as bromide dermatoses. Later, Stevenson (*Arch. Dermat. & Syph.* **12**:525 [Oct.] 1925) elaborated on the original work of Wile and his associates. Harris and Hauser failed to mention the work of Wile, Wright and Smith, and of Stevenson.

Furthermore, and apart from Harris and Hauser's report, the technic of Belote for the detection of bromides in the body fluids also deserves remention in connection with Wuth's paper (The Journal, June 25, 1927, p. 2013). It is a most simple test, involving the color change induced by bromine whereby the yellow of fluorescein paper becomes the pink of eosin (Belote: The Journal, May 28, 1927, p. 1696).

Without mention of these authors, the credit for an important and even life-saving method of treatment might be permanently lost.

Fred D. Weidman, M.D., Philadelphia.

VIOSTEROL IN RICKETS

To the Editor:—I am much interested in your editorial comment in The Journal, September 13, on "Vitamin A in Disease." Toward the end of the editorial appears this statement: "Recently viosterol has come into vogue in the treatment and prevention of rickets. Because of its high vitamin D content it should be more valuable than cod liver oil, but in certain cases cod liver oil has seemed to be more curative than viosterol." Some research work that we have done at this institution with irradiated ergosterol as an antirachitic for chickens indicates clearly that the standard established for this product by the Council on Pharmacy and Chemistry of the American Medical Association is entirely out of line with the real antirachitic value of this product. We have fed irradiated ergosterol, or viosterol, in amounts theoretically equivalent to 2, 4, 6, 20, 50, 100 and 200 per cent of cod liver oil, and not until the last mentioned amount was included in the ration were we able to prevent rickets in chickens. As a matter of fact, even the lot receiving the theoretical equivalent of 200 per cent of cod liver oil in the form of viosterol was subnormal in bone ash and in bone structure as compared with the control lot which received 2 per cent of cod liver oil.

May I suggest that some of the early investigations with irradiated ergosterol may have resulted in faulty conclusions because rats were used as the experimental animals. Rats, of all animals available for rickets work, appear to be least desirable because the species has been evoluting in dark and shadowy environments for a million years or more, and consequently the type with the lowest ultraviolet or D requirement has been evolved. The fact that thousands of rats were used in various vitamin research experiments before the D factor was discovered indicates that rats have an extremely low requirement for this factor. Birds, on the other hand, have a relatively high D requirement because of their evolutionary background. We do not suggest that birds are exactly the ideal type for D research work, but do feel that faulty conclusions are being reached through the use of rats for this particular type of experimentation.

So far as we can determine from a review of the literature, there are no data from experiments with human beings that would conclusively indicate that the Council on Pharmacy and Chemistry standards for viosterol are correct.

F. E. Mussehl, Lincoln, Neb.
Chairman, Poultry Husbandry Department,
College of Agriculture.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

MEDICAL AND ETHICAL ASPECTS OF STERILIZATION

To the Editor:—I am engaged in medical missionary work in a thickly inhabited district of China. Part of my time is spent at a foundling asylum. As is well known, China is overpopulated and the birth rate is high. *There is little knowledge of birth control, and abortion is comparatively uncommon.* Two factors that offset to some extent this situation are high infant mortality and the refusal on the part of many families to rear their babies. The first is intolerable from a medical standpoint. The second is intolerable from a moral point of view My questions, then, are: 1. Has modern gynecology any fairly reliable surgical procedure for sterilizing women which is practicable by an ordinarily trained surgeon? 2. Does such a procedure have any deleterious effect on the personality and sex life of a woman? 3. What, in your opinion, would be the attitude of reasonable and ethical medical men toward such a proposition as this: That any woman who has four living children may apply to a hospital and have the sterilizing procedure carried out if her health permits, with no embarrassing insinuations made, and at a minimum of expense—possibly paid by the state?

George Thorngate, M.D., Liuho, Kiangsu, China.

Answer.—1. There are a number of fairly reliable surgical procedures for sterilizing women, but not one of them is absolutely dependable except removal of all ovarian tissue. The roentgen rays and radium may also be used to produce sterility, but they have the disadvantage of bringing about an artificial menopause. The simplest surgical treatment is that recommended by R. L. Dickinson; namely, occlusion of the tubal openings inside the uterine cavity by means of an electric cautery. This method, however, is not much used. Among the intra-abdominal procedures the one most commonly employed is the following: A ligature is placed around the tube about 2 cm. from the uterine cornu. The uterocornual junction is excised, the proximal end of the tube is buried within the folds of the broad ligament, and the cornu of the uterus is sutured and covered with peritoneum. The same procedure is carried out on the opposite side. A much simpler and just as effective method is the Madlener operation, which consists of elevating the midportion of each tube, gently but firmly crushing it with a smooth clamp, and placing a heavy silk ligature in the groove produced by the clamp. This method is simple, bloodless and quickly performed and is especially useful when sterilization is necessary at the time a cesarean section or hysterotomy is performed.

2. Sterilization operations performed on the tubes have no effect on the personality or sex life of the individual. If the patient is not informed of what has been done, she will have no subjective or objective indications that she has been sterilized other than that she cannot conceive.

3. This question is a complex one and should be answered by sociologists, not by medical men. On purely medical grounds there is no reason to refuse such a request, although at the present time the usual indication for sterilization is just the reverse of the one mentioned. Practically the only time sterilization is now carried out is for some serious medical ailment. An exception to this is the woman who has had a number of cesarean sections. Undoubtedly if such a proposition were made to medical men, many of them would oppose it because of religious beliefs.

OBESITY AND GLYCOSURIA

To the Editor:—A man, aged 54, obese, weighing about 280 pounds (127 Kg.), and about 5 feet 6½ inches (167.7 cm.) tall, has had a constant glycosuria for the past three years. Previous to this, it was an *intermittent one. His blood sugar was 210 mg.* per hundred cubic centimeters of blood about three years ago. Several weeks ago his blood sugar was 360 mg. A quantitative examination of the sugar in the urine showed about 5.5 per cent sugar. No acetone or diacetic acid was found in the urine. The patient's weight is constant and has not diminished for the past seven years. He has symptoms that point to a nerve involvement and has numbness of the feet, especially the heels. He also complains of indefinite pain in the epigastrium. Will you kindly state whether insulin is indicated and how much in this case because of the high percentage of sugar in the urine and the high sugar content of the blood? The patient has been on a diet all this while which, however, is not sufficient to control the glycosuria. What is the likely cause of this pain in the abdomen? It has no relationship to meals, coming on at irregular times. The patient is a clerical man. Kindly omit name.

M.D., Wisconsin.

Answer.—Analysis of this story makes it seem highly probable that unless a diet is instituted which will result in the patient losing considerable weight there is little chance of reducing either his glycosuria or his hyperglycemia. The experience with patients of this type suggests, as Joslin has so frequently pointed out, is that the obesity is a precursor to the diabetes; and a man of these dimensions is certainly tremendously overweight. It is also true that many patients of this type who claim to be on a diet actually are *not*, for the diet in such a patient must be low in calories as well as in carbohydrate.

The description of the various pains suggests diabetic neuritis. It does not seem wise to use insulin at the present time for a simple reason: Insulin will result in the utilization of more food, and therefore an increase in weight. A vicious circle is thus established. Perhaps under careful dietary control the patient will become sugar free but, if not, it might be wise to reduce his fat intake tremendously and give him small doses of insulin to assist in the utilization of what carbohydrates are necessary. This type of diet has been described by Evans and Strang.

DIET RESTRICTIONS WITH MILD MERCUROUS CHLORIDE (CALOMEL)

To the Editor.—Please express the present-day thought as to dietary restrictions applying to a patient taking calomel, with particular reference to fruit and vegetable acids, and to milk. Kindly omit name.

M.D., West Virginia.

Answer.—There is no scientific reason for dietary restriction or avoidance of acid fruits in connection with the use of mild mercurous chloride.

EFFECTS OF SODIUM NITRATE IN POWDER MANUFACTURE

To the Editor:—We (Apache Powder Company) are interested in the literature on the subject of the untoward effects of prolonged exposure to sodium nitrate in the manufacture of powder. We have an employee who has worked in the nitrate for the most of his eleven years' employment and who has low blood pressure, low *hemoglobin* and low basal metabolism alleged to be due to exposure to sodium nitrate. However, he has also Argyll Robertson pupils, diminished knee jerks, ataxic gait and positive *Romberg sign*, which suggests tabes; but the blood and spinal fluid Wassermann, Kahn and serum globulin reactions and the colloidal gold curve are all negative. Therefore we are interested to know what, if anything, has been written on the effect of exposure to sodium nitrate on man, and will appreciate any information you may supply as to where we can find reference to such literature.

R. C. Kirkwood, M.D., Benson, Ariz.

Answer.—For generations nitrates have been manipulated by workers, in the manufacture of explosives, without having attracted the attention of industrial hygienists or toxicologists as a source of harm. The inference is that these substances are not frequent causes of significant harm to workmen. Opinions as to sodium nitrate toxicity are largely based on its chemical similarity to potassium nitrate, more being known about the toxic properties of the latter. Acute poisonings from accidental ingestion of nitrates are well known. This phase is well covered by Peterson, Haines and Webster in their textbook "Legal Medicine and Toxicology" (Philadelphia, W. B. Saunders Company, 1923). A fatal case of nitrate poisoning was described in The Journal by Windmueller (Sept. 10, 1921, p. 858). Additional data may be derived from Sollmann's "Manual of Pharmacology" (Philadelphia, W. B. Saunders Company, 1927) and Solis-Cohen's "Pharmaco-Therapeutics" (New York, D. Appleton & Co, 1928).

From all sources it seems likely that nitrates are changed to nitrites to some extent in the body, and that bodily responses are in part characteristic of the latter. Lowered blood pressures, anemia and subnormal metabolic rates have been described. Diuresis, gastro-enteritis, myalgias, partial blindness and tachycardia likewise have been observed. Windmueller's patient presented manifestations quite dissimilar to those indicated in this query.

AUFRECHT'S METHOD OF TREATING PNEUMONIA

To the Editor:—May I have details of Aufrecht's method of the treatment of pneumonia by means of injections of quinine?

J. C. Parham, M.D., Port au Prince, Haiti.

Answer.—Aufrecht said in a recent article that the prescription he uses consists of 2 Gm. of quinine hydrochloride, 1 Gm. of urethane (ethyl carbamide), and 20 Gm. of distilled water. The urethane permits the dissolving of the quinine hydrochloride in a small quantity of water. When this mixture is used, 0.5 Gm. of quinine hydrochloride can be administered in 5 Gm. of fluid. The usual number of injections required is two or three, given at twelve or twenty-four hour intervals. The best site for the injections, Aufrecht said, are the lateral abdominal walls. If the injection is made carefully and the needle removed slowly by pressing a cotton compress on the skin around the puncture, there is no bleeding and the injected fluid spreads easily in the loose tissue. When the distilled water is too cold, the quinine precipitates, but it can be dissolved again if the container is placed in a warm water bath. Aufrecht employed quinine therapy only in lobar pneumonia and not in bronchopneumonia or pneumonia due to the Friedländer bacillus. All his patients were adults. In several hundred cases treated he did not note any complications. Aufrecht injected the quinine subcutaneously. Berger reports favorable results with injections intramuscularly into the extensor muscles of the thigh. Although quinine has been used in the treatment of pneumonia, its value has not yet been fully demonstrated; furthermore, all recent work seems to show that intramuscular injections are absorbed less efficiently than oral.

THE ANOPHELES AND MALARIA

To the Editor:—In the past, malarial infection was said to be carried by the anopheles mosquito. Recently in Lake County, Ind., there have been reported various cases of malaria. Is there any recent report that malaria may be transmitted by other mosquitoes besides anopheles?

B. B. Reeve, M.D., Whiting, Ind.

Answer.—It is accepted as almost a truism that human malaria can be transmitted only by anophelene mosquitoes. Certainly there is an enormous literature proving the importance of anophelenes and there are no recent reports giving any valid evidence that mosquitoes, other than anophelenes, can carry the disease. The fact that anophelenes are so important has served to lessen interest in the culicine species and as a consequence there is little carefully controlled experimental work showing that the culicine species cannot be infected with human malaria.

The recent work of C. G. Huff on avian malaria (which is generally carried by culicine species) is interesting in this connection (*Ann. Trop Med.* **23**:427 [Dec.] 1929). He finds that the susceptibility of mosquitoes to malaria is not solely a species characteristic but is largely an individual idiosyncrasy determined by heredity. This probably will help to explain why a given species of anopheles may be a dangerous carrier in one locality and not in another. Huff also believes that it is likely that if a large number of culicines were fed on infected human beings a few would become infected. All of this is highly speculative and must await further experimental work.

ANNULUS OF VIEUSSENS

To the Editor:—What is the "annulus of Vieussens" that Sutton and Lueth removed so often? My dictionary defines it as the same as "annulus ovalis," which is the "margin of the septum of the foramen ovale of the fetal heart." I don't see how they could have gotten away with the resection of that or how it would have given the results they obtained from its extirpation.

L. M Blackford, M.D , Atlanta.

Answer.—The ansa subclava of Vieussens is the more anterior of two sympathetic nerve bundles connecting the middle and inferior cervical ganglions of the sympathetic on each side of the neck. This nerve bundle, instead of going directly from the middle to the inferior ganglion, extends downward in front of the subclavian artery, and turns backward beneath that artery and then upward behind it to join the inferior ganglion. On its course it usually gives off a middle cardiac nerve and a filament to the recurrent nerve as it extends upward from the vagus to the esophagus, trachea and larynx. The reason for the curious course of this bundle is that during development the subclavian artery on each side has moved caudad from its primary position in the front of the neck, descending in front of the inferior ganglion and thus producing an elongation of that bundle of nerve fibers connecting the two ganglions in front of it while the other bundle connecting the two ganglions behind it remains of the same length. This ansa, described by the French anatomist Vieussens about 1700 A. D., must not be confused with the ring of musculofibrous tissue (annulus ovalis Vieussenni) which surrounds the foramen ovale and the septum ovale of the heart, which he also described.

TREATMENT OF PARKINSONIAN DISEASE WITH STRAMONIUM

To the Editor:—I have been afflicted with parkinsonian disease for five years. I have taken scopolamine, 1/150 grain (0.4 mg.), three times a day; parathyroid, 1/10 grain (6 mg.) daily, also autocondensation, which seems to help a little. Can you suggest anything in the way of treatment; e. g., stramonium? My worst symptom is the tremor.

M.D., Oregon.

Answer.—Stramonium, perhaps more than scopolamine, does seem to have some effect in reducing the rigidity of the parkinsonian syndrome that follows epidemic encephalitis, though they have little effect on the tremor, as a rule, and are of little value in true Parkinson's disease or paralysis agitans. Nothing that has yet been discovered has much influence in most cases in this last condition.

SENSITIVITY TO HEAT AND COLD

To the Editor:—I have a case which is giving me, as well as others, a real workout: A man, aged 55, of rather spare build, well nourished, had gallbladder drainage several years ago. About three years ago he developed a skin condition which gives him real annoyance. It itches continually and on being scratched leaves small scabs. The patient can remain indoors for two weeks and it completely disappears, but when he goes out again in sun, wind and dust, it immediately reappears. He has been through several clinics without result. He has just come home from the University Hospital at Omaha after a stay of several weeks, during which no infection or organic trouble was found. The skin department diagnosed the trouble as eczema of the neurodermic type and put him on sodium thiosulphate, 1 Gm. intravenously every two weeks, and I am still giving this treatment. He has tried other treatment without results. If you can give me any pointers it will be greatly appreciated.

C. A. Miller, M.D., Thedford, Neb.

Answer.—It is quite possible that the case described is sensitive to heat or effort or to cold. The condition is described in the February issue of the *Archives of Internal Medicine* under the heading Heat and Effort Sensitiveness and Cold Sensitiveness. The patient can be tested objectively by exposing him to a large nitrogen lamp until his skin is hot and later to cold by rubbing him from head to foot rapidly with ice. If either heat or cold augments the itching, a positive diagnosis of heat or cold sensitiveness can be made. The case can probably be successfully treated through the repeated alternations of hot and cold application.

ABSORPTION OF DEXTROSE—HYPODERMOCLYSIS

To the Editor:—1. In The Journal, July 12, appeared the query "Is there any authoritative opinion on the rate of absorption and the change in blood sugar concentration following dextrose by rectum and by hypodermoclysis?" I wonder whether in making his reply the editor fully considered the article by McNealy and Willems (Surg. Gynec. Obst. **49**:794 [Dec.] 1929), wherein a plausible conclusion is reached that dextrose is not absorbed by the rectum or the colon. I would appreciate further opinion on this topic in that rectal feedings of dextrose are practiced so frequently and so much faith is held in their nutritional value. I myself am inclined to believe with McNealy and Willems. 2. There has been considerable discussion lately in our circle as to the wisdom of hypodermoclysis given in the thighs in preference to the subpectoral insertion. This area used almost exclusively by our group has temporarily been given up because of two instances of sloughing following the clysis, whereas sloughing following a subpectoral hypodermoclysis has never occurred I would appreciate your opinion in the matter both as to the region of choice and as to the probable explanation for the sloughing. At present we are considering three factors as probably responsible: (*a*) a hypertonic solution; (*b*) too rapid instillation; (*c*) too concentrated a solution of iodine in preparing the field. 3 Is there any contraindication for giving dextrose 5 per cent in physiologic solution of sodium chloride either as a hypodermoclysis or intravenously? Please omit name.

M.D., Connecticut.

Answer.—1. The observations of McNealy and Willems might well explain the generally contradictory evidence available from the literature. It may well be that those observers who secured evidence of absorption or of antiketonic action from rectal administration of dextrose employed a technic that forced the material past the ileocecal valve.

2. Injection in the thigh does not seem to be as well borne as injection into the looser and larger subcutaneous tissue

space of the front of the trunk. Infections, even with gas bacillus and tetanus, seem to occur with greater frequency in thigh injections than elsewhere. Possibly distention in this region interferes with local nutrition more than in the subpectoral region.

3. Dropsy, pulmonary edema and marked cardiac insufficiency are definite contraindications to voluminous subcutaneous or vein infusion.

FLUCTUATION IN SUGAR TOLERANCE

To the Editor:—A 60 year old patient of mine had to maintain a very strict diet to keep free from sugar. I was quite surprised to find that the urine was sugar free and that he had been eating "everything" and feeling fine after taking "Glucosin." Kindly give me your comments on the remedy mentioned. Please omit name and town.

M.D., New York.

Answer.—The proprietary preparation mentioned is probably without any value whatever. The result noted is evidently due to a natural fluctuation in sugar tolerance. An infection might have temporarily lowered the patient's sugar tolerance, which improved on his recovery from his infection. Profound emotional disturbance will temporarily lower sugar tolerance. On the other hand, suitable strict dieting may raise the sugar tolerance; and any remedy used afterward might erroneously be given credit for a result that had been achieved by the previous treatment.

ASPERMIA AND AZOOSPERMIA

To the Editor:—In Queries and Minor Notes (The Journal, August 30, p. 683) you use the term "aspermia" to designate the absence of sperma from the seminal secretion. In the case referred to, the semen was examined and no sperma found. The usual designation of this condition is "azoospermia," meaning the absence of sperma. "Aspermia" is used to signify an absence of ejaculation. It is true that the two terms are often used interchangeably to designate the absence of sperma from the semen, but both cannot be correct. Will you kindly explain your use of "aspermia"? Do you consider this the correct term, as against "azoospermia?" And if so, when would you use the latter term?

A. L. Wolbarst, M.D., New York.

Answer.—The editor erred in the title placed on the question referred to and also in the use of the term in the answer. General usage tends to confirm the point of view of Dr. Wolbarst to the effect that aspermia signifies an absence of ejaculation or deficient secretion of semen and that azoospermia indicates an absence of sperm and a lack of spermatozoa in the semen.

CARMINATIVE ACTION OF ONION

To the Editor:—Recently I have heard of, and in fact seen, the following "home remedy" used and apparently work as well as paregoric in preventing young infants from crying and fretting. Can you give me any explanation as to the mode of action, the vegetable compound involved, or any injurious results from giving infants a few drops of the following concoction: Slice an onion thin, place it in a glass dish and sprinkle a thin layer of vinegar over it. Leave for twenty-four hours, and give the resulting fluid in 2-3 drop doses. It makes a child sleep and seems to cause no trouble.

William C. Holt, M.D., Angleton, Texas.

Answer.—The effect observed is probably due to the carminative action which the onion is reputed to have.

DERMATITIS FROM TRINITROPHENOL

To the Editor:—Please inform me as to whether or not there is any specific treatment for the severe dermatitis that occasionally occurs following the use of trinitrophenol, alcohol solution, in abdominal preparation of surgical patients. In 2 cases out of approximately 500 there occurred a rash that spread till it finally covered the entire body, and even invaded the mucous surfaces. It is extremely distressing and does not subside for about ten to twelve days.

W. H. Bennett, M D., Lamesa, Texas.

Answer.—Trinitrophenol (picric acid) remaining at the point of original application may be removed from the skin by a paste of magnesium carbonate. Otherwise the dermatitis would have to be treated in accordance, with the recognized principles of dermatology.

INTRAVENOUS THERAPY

To the Editor:—Please advise me whether there is any advantage in giving cinchophen, sodium salicylate and sodium iodide intravenously instead of by mouth. Harry H. Bolton, Jr., M D., Pierce, W. Va.

Answer.—Unless special conditions make the intravenous route necessary, the intravenous administration of these drugs is not indicated.

Maryland June Examination

Dr. Henry M. Fitzhugh, secretary of the Board of Medical Examiners of Maryland, reports the written examination held at Baltimore, June 17-20, 1930. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. Eighty-eight candidates were examined, 87 of whom passed and 1 failed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
College of Medical		87.8
Yale University Sch		85.8
Georgetown Universi		75.2
George Washington		84.4, 87.5, 88, 89.6, 91.6, 91.8
University of Illinois College of Medicine	(1930)	89.3
Johns Hopkins University School of Medicine	(1924)	89.5, (1927) 87.1, (1928) 91.8, (1929) 80.1, 83.8, 85, 96.3, (1930) 80.3, 80.5, 81.5, 81.7, 82, 82.1, 82.6, 83, 83.2, 83.3, 84.6, 84.8, 85, 85.4, 86, 86.1, 86.6, 86.8, 88, 88.6, 89, 89, 89.2, 89.4, 89.7, 90.1, 90.5, 91.4, 91.8, 92.5

Book Notices

TREATMENT IN GENERAL PRACTICE. By Harry Beckman, M.D., Professor of Pharmacology at Marquette University, Milwaukee. Cloth. Price, $10 net. Pp. 899. Philadelphia: W. B. Saunders Company, 1930.

Here in book form is the therapeutic index or scrap book that every general practitioner wishes he could prepare and keep for himself. The author has apparently stored in envelops, on cards or by some other indexing method references to most of the important articles on therapeutics that have appeared in medical publications in recent years. He has carefully abstracted and condensed this material and he has used sound editorial judgment in his choice of suggestions that are most worth while. The result is a book on therapeutics that is probably the most practical large book at present available. It is arranged according to diseases of infectious and parasitic causation, allergic disturbances and diseases of the various systems of the body. It includes also intoxications, a special section on burns, obstetrics and a number of miscellaneous subjects.

The material is in practical form for immediate application at the bedside. As with most extensive works of this character, it would seem that the author has distributed the space available occasionally with a desire for elaborateness rather than with a view to the most practical demand for material. The general practitioner will hardly require ten pages on the treatment of leprosy. He could probably use much more on the treatment of measles. He will certainly have little, if any, use for seven pages on plague, but twenty-five to thirty pages on pneumonia are well warranted. Dr. Beckman seems to be somewhat favorably inclined to the Rosenow serum in poliomyelitis, giving it much more space than is devoted to the use of convalescent serum, whereas the latter is much more generally preferred. The treatment of rheumatic fever is, no doubt, a most difficult one and certainly cannot be well handled in four pages. The section on syphilis is fully adequate.

An exceedingly valuable feature of the book is the use of historical and literary quotations preceding the main topics. The author does not hesitate to give exact directions for securing the materials and drugs recommended. Occasionally, his choice of authorities is not what it might be; thus, his section on obesity is taken practically verbatim from Sansum and disregards some of the most important recent contributions to the subject. The section on nervous indigestion is quoted almost wholly from the exceedingly fine contributions of Alvarez. Indeed, there are apparently some ten pages of this quotation. The author is also inclined to follow Alvarez in his treatment of peptic ulcer.

This volume is exactly what is stated in the preface, a collection of excellent abstracts and quotations from the best available literature. It was Josh Billings who said that wit represented a good memory and the ability to choose with judgment. In the same way the preparation of a work on therapeutics of this type represents an organized system for the collection of the best that appears in medical literature, and the ability to reproduce and develop this material in textbook form. In the time that has elapsed since its appearance, the book by Beckman has developed great popularity—a popularity warranted by its practical character and usefulness.

APHORISMES DE MÉDECINE CLINIQUE. Par le Baron Corvisart. Recueillis par F.-V. Mérat. Publiés par le Docteur Paul Busquet, bibliothecaire de l'Académie de médecine. Paper. Price, 20 francs Pp 115. Paris: Masson & Cie, 1929.

Corvisart, Napoleon's physician, was not a prolific writer. He is known especially because of his valuable volume on diseases of the heart, and because he translated and brought to the attention of the medical world Avenbrugger's treatise on percussion. Yet he was a leader and pioneer in clinical medicine in Paris, with a great influence on such men as Laennec through his emphasis on the importance of careful observation with necropsy control. He was a forceful teacher and was fond of epigrammatic statements. Many of these, collected by Mérat, chief of staff of the faculty of Paris, are now for the first time published, with comments, by Busquet. They are well worth reading. Some have naturally lost their point through later discoveries as to the nature of certain diseases, but many of his apothegms are as true today as they were a century ago. From his first to his last, number 324, the interest is maintained. The first: "Medicine is not the art of curing diseases; it is the art of treating them." The three hundred and twenty-fourth: "Purple digitalis, proposed as a remedy against phthisis and dropsy and especially as a drug for lessening the frequency of the pulse, has, in my experience, been successful only once in about seven trials. That was in a case in which it slowed the pulse."

THE NORMAL DIET: A SIMPLE STATEMENT OF THE FUNDAMENTAL PRINCIPLES OF DIET FOR THE MUTUAL USE OF PHYSICIANS AND PATIENTS. By W. D. Sansum, M.S., M.D., F.A.C.P., Director of the Potter Metabolic Clinic, Department of Metabolism, Santa Barbara Cottage Hospital, Santa Barbara, California. Third edition. Cloth. Price, $1.50. Pp. 134. St. Louis: C. V. Mosby Company, 1930.

The author of this work lives in California and he displays a strong preference for such products as oranges, lemons, grapefruit and beans. The book has been quoted extensively and pushed vigorously by the California Fruit Growers Exchange Campaign. The author believes that fully one half of the sickness that has come under his observation has been due, either directly or indirectly, to the elimination of the bulky foods from the diet. He states that the average constipated person requires approximately two pounds of the residue-containing foods daily to insure natural bowel movements and he has his office patients weigh and record the bulky foods. He considers acidosis from an overbalance of the acid-ash foods a great danger. He says: "The living body is always slightly alkaline. If the tissues of the body become acid to the slightest degree, death occurs, and serious illness results long before the alkalinity of the body is reduced to the neutral point. The more common symptoms of the acid-ash type of acidosis are malaise, lassitude, nausea and later vomiting, loss of appetite, headaches, weakness, sleeplessness, muscle aches, acid mouth, sour stomach, acid urine, acid sweat, 'sour disposition,' and, I believe, the blood vessel disease which is responsible for high blood pressure and such complications as partial blindness, heart disease, kidney disease, gangrene and apoplexy." He does not say just how acid the body must be to produce these symptoms but he does state that serious degrees of acidosis may be produced by eating too much bread and meat and that a urine which is acid enough to turn blue litmus paper to red is far too acid and a urine which is alkaline enough to change red litmus paper to blue is probably too alkaline.

The little book by its misstatements seems continually to twist truths to make them support the alkaline-ash, high-residue fad. For example, the author groups cascara, rhubarb, phenolphthalein and castor oil with "the concentrated vegetable and mineral irritants" which "act upon the inner lining of the stomach and bowel in the same manner as an irritating substance affects the eye which 'waters' when such a substance comes in contact with the conjunctiva. . . . And it is the 'tears' on a large scale which produce the copious, unnatural, watery bowel movements." His knowledge of the science of nutrition seems to be weak, for he speaks of proteins as the chief sources of muscular energy. Thus the woman shopper gets a headache long before noon because she does not eat a large breakfast. She has consumed her own fat and so much of her own protein that its acid-ash has caused an acidosis. Benedict's fasting artist, Levanzin, managed to starve for thirty-one days without increasing his protein metabolism above the normal level, but Sansum's shopper apparently could not last half a day. He makes another remarkable statement about a football game: "Whereas 3,500 calories per day is sufficient for a man doing average work, and 5,500 calories is the army ration, our college football players often use up 8,000 calories during the game. They enter such games without food or with a very light lunch. Their energy comes from the burning of their own lean meat, and the more muscular they are the more endurance they seem to have." It is a simple matter to calculate the result of such a football contest. Lean beef round furnishes 512 calories a pound and therefore Sansum's athlete would lose in the course of the game $15\frac{9}{10}$ pounds of muscle. He would have to eliminate approximately twenty times as much urea as the ordinary man does in a whole day and this would require about 5 or 10 pounds of urine over and above the amount of water furnished by the breakdown of this muscle tissue. Now Benedict and Joslin calculate that a football player in a hard game loses about 13 7/10 pounds of water through skin and lungs. This would make Sansum's man lose between 34 and 39 pounds of weight in the course of little over an hour. Sansum does not explain just why a football player expends from thirteen to fourteen times as much energy per hour as bicycle riders on a century run or swimmers or mountain climbers. A textbook of physiology would give him the figures and any good textbook written during the last two generations would tell him that physical exercise causes practically no increase in the protein metabolism.

The book is of some service in that it emphasizes the value of plenty of water in the treatment of fevers and demonstrates to the public the fact that orange juice and lemon juice act as alkalis when metabolized. On the whole, its biased point of view makes one doubt the extent to which it should be trusted.

Die Betrachtung und Betastung (Inspektion und Palpation) des Brustkorbs bei Lungenkranken. Klinische Untersuchungen uber diagnostisch wichtige Erscheinungen am Knochengerüst, an Muskeln und Haut, sowie am Nerven- und Gefasssystem des Brustkorbs, mit besonderer Berucksichtigung halbseitiger Veranderungen. Von Oberarzt Dr. J. E. Kayser-Petersen, leitendem Arzt der Tuberkulose-Fursogestelle fur den Stadtkreis an der medizinischen Universitats-Poliklinik. Paper. Price, 21 marks. Pp. 213, with 39 illustrations. Leipzig: Johann Ambrosius Barth, 1930.

Physicians are so accustomed in examining the chest for pulmonary disease to rely largely on percussion and auscultation, and the x-rays that they overlook the many aids furnished by inspection and palpation. It is enlightening to read such a book as this one and to see how much information is afforded by the use of the eyes and the fingers. Slight deformities, asymmetry, loss of motion, change of color, points of tenderness and change in muscle tension may be mentioned as examples, each with its possible significance as to underlying disease. There are several useful diagrams with brief case histories, together with the roentgen and auscultatory observations. The book is stimulating and timely. It will help call attention to the fact that careful physical examination is still of use and should not be displaced entirely by the laboratory or instrument of precision.

Diseases of the Urinary Tract in Children. By Edwin Beer, M.D., and Abraham Hyman, M.D. Cloth. Price, $6. Pp. 318, with 50 illustrations. New York: Paul B. Hoeber, Inc., 1930.

The authors base their work on twenty years' experience with diseases of the genito-urinary tract in children. The preliminary chapter is devoted to the symptomatology of genito-urinary disease in young life. The technic of cystoscopy and pyelo-ureterography is discussed in some detail. Intravenous pyelography by the use of sodium-2-oxo-5-iodo-pyridine-n-acetate is described and its advantages and indications are pointed out. The use of the Bucky diaphragm is not advised. Edwin Beer writes on enuresis in childhood. He emphasizes the need for a thorough examination in order to determine the etiologic factor. Hyman writes the important chapter on infections of the urinary tract (cystitis, pyelitis, pyelonephritis). He presents the most recent contributions to bacteriologic, experimental, surgical, cystoscopic and roentgenographic progress. He appropriately avers that "pyelitis" is a misnomer which covers a number of conditions, and that "pyuria" is more applicable until the true nature of the underlying lesion is understood. He observes that a large proportion of the chronic pyurias in children, formerly diagnosed as pyelitis, are secondary to urinary stasis due to a congenital anomaly. The author believes that too much emphasis has been placed on the hematogenous theory of kidney infection. He thinks that, of all the predisposing factors favoring infection, urinary stasis and a diminished resistance are the most important. An uncomplicated pyelitis seldom exists; accompanying lesions are found in the kidney in most necropsy specimens. The author notes that persistence of infection is due to lowered immunity, to a calculus in the kidney or ureter, to a persistent suppurative focus somewhere else in the body, or to a urinary stasis caused by a congenital anomaly. Edwin Beer discusses abscess and carbuncle of the kidney. He notes that in cases of cortical abscess in which the symptoms have subsided and diagnosis is difficult, activation of the focus by injecting *Staphylococcus aureus* vaccine in a dosage of from 100 million to 500 million acts as a provocative test and accentuates the clinical manifestations. He points out, as an important radiographic sign in the diagnosis of perinephric abscess, the obscuring of the outer border of the psoas muscle and *curvature of the spine to the opposite side.* Edwin Beer contributes a chapter on injuries of the kidney and ureter. He notes that the most striking symptoms are hematuria, local pain, local tumor and more or less shock with bleeding as shown by the fall in the hemoglobin of the blood. He advises that in *observing these cases of injury to the kidney* and ureter one should see every voided specimen of urine and use a rack of test tubes. It can thus be seen at a glance whether the bleeding is ceasing or continuing. Instrumentation may lead to infection and the author considers it contraindicated except when the diagnosis is in doubt. Beer writes the chapter on chronic tuberculosis of the kidney. He states that the all important examinations are urinary and cystoscopic. However, he cautions that in renal tuberculosis pyelography should be the diagnostic method of last resort. The resulting trauma may produce generalized tuberculosis. Hyman considers malignant tumors of the kidney and believes that the most frequent type is the mixed embryonic tumor. This monograph presents the essential clinical and special urologic data in a clear, practical manner. Each chapter is concluded by a group of illustrative case records and a special bibliography. There are numerous instructive roentgenographic reproductions. The volume should be valuable and interesting to pediatricians and urologists.

Le neurosi del cuore e dei vasi sanguigni e loro cura. Dal Prof. Giovanni Galli, docente di patologia medica speciale nella R. Università di Pavia. Paper. Price, 50 lire. Pp. 361, with 98 illustrations. Milan: Società Editrice Libraria, 1930.

Galli defines a neurosis as a disease situated in the smaller blood vessels with material lesions that are physical or chemical, as a rule entirely reparable, leaving no anatomic residue. A neurosis is in close relation with the psyche and gives rise to many subjective and objective manifestations that vary according to the organ or the part in which the circulatory disturbance takes place. All through the work while physical, chemical, toxic and other causes are recognized, the stress is laid on psychic influences. There is nearly as much discussion of psychology as of cardiology and neurology. The topics considered are such as tachycardia of various types, extrasystole, palpitation, the nervous heart, respiratory arrhythmia in the circulatory neuroses, hypotension and hypertension on a nervous basis, visceral vasomotor syndromes, vasomotor syndromes of the skin and joints, circulatory neuroses on a sexual basis, psychoanalysis and moral guidance. Not the least interesting and stimulating of his chapters are the earlier ones that are largely historical. The author rarely goes to extremes in his views. He seems possessed of plenty of common sense. Thus while recognizing the value of freudian psychoanalysis he makes it plain that he is not a "pansexualist." His therapy is likewise sound though with a greater faith in drugs than one would expect from his emphasis on the mental features of these neuroses. Galli is a loyal Italian. Exophthalmic goiter is with him Flajani's disease. He also refers to the Morgagni-Adams-Stokes syndrome. There are numerous figures showing polygraphic tracings but none showing electrocardiograms. A new font of type and a little more care in proofreading would have improved the looks of the pages. These, however, are minor criticisms. All in all the book is to be praised as a serious and helpful contribution to the better knowledge and handling of a group of ailments as yet none too well understood.

Burns: Types, Pathology and Management. By George T. Pack, B.S., M.D., and A. Hobson Davis, B.S., M.D., Instructor in Pathology, University of Alabama. Cloth. Price, $6. Pp. 364, with 60 illustrations. Philadelphia: J. B. Lippincott Company, 1930.

The authors of this volume are to be congratulated on the masterly manner in which the subject of burns is presented. This excellent treatise is not a mere compilation of data but *an amalgamation of a critical selection of the best in the literature* with the results of a wide clinical experience. The preface states: "In the preparation of this manuscript, we have included not only our personal experiences, but also a *free-analysis* of the contributions and opinions of other clinicians and investigators." The senior author was initiated into the management of burns by the incidence of a theater fire in New Haven in 1921 and since then has been associated with a second similar disaster and with the study of many individual cases. This experience has given to him an authority seldom encountered. The book is divided into three parts. Part one contains fundamental facts concerning burns and scalds. The historical aspects of the subject are presented together with a discussion of the etiology, incidence, classification, pathology and cause of death. In part two, consideration is given to the management of thermal burns. Particularly important is the chapter on the character of the immediate treatment of the burned patient and the emphasis laid on the necessity of systemic treatment. "It is the physician's duty to treat the patient as well as the burn and by supportive systemic therapy obviate any visceral mischief and malnourishment." Local treatment of the injury is given a duly prominent position and is discussed from many points of view. The relative merits of various procedures, such as wet dressings, water bath treatment, sunlight therapy and occlusive dressings (paraffin, oils, ointments and powders) are indicated. The technic of skin grafting, the diseases of cicatrices following burns and the prevention and correction of subsequent deformities are critically reviewed and preferred methods selected. In part three, regional burns by specific agents are discussed. This includes burns by such agents as electricity, lightning, roentgen rays, radium, the sun, caustic chemicals and the war gases. The final chapter presents the medicolegal aspects of burns and scalds. There are adequate references to the literature at the end of each chapter, and both subject and author indexes are given. The text is brief, clear cut and decisive. A perusal of this volume gives the feeling that in the present stage of knowledge little can be added to this presentation of burns and nothing can be deleted.

Allen's Commercial Organic Analysis. A Treatise on the Properties, Modes of Analysis, and Proximate Analytical Examination of the Various Organic Chemicals and Products Employed in the Arts, Manufactures, Medicine, etc. With Concise Methods for the Detection and Estimation of Their Impurities, Adulterations, and Products of Decomposition. Volume VIII: Glucosides, Non-Glucosidal Bitter Principles, Enzymes, Putrefaction Bases, Animal Bases, Animal Acids, the Cyanogen Compounds, the Proteins, the Digestion Products of Proteins. Edited by C. Ainsworth Mitchell, M.A., D.Sc., F.I.C. Fifth edition. Cloth. Price, $7.50. Pp. 761, with illustrations. Philadelphia: P. Blakiston's Son & Company, Inc., 1930.

This volume has been entirely rearranged, revised and in some instances partially rewritten. The scope of the book is broad. It contains ten sections, which have been prepared by different authors or co-authors, except three, these being written by the same writer. The sections are on glucosides, nonglucosidal bitter principles, enzymes, putrefaction bases, animal bases, animal acids, the cyanogen compounds, the proteins, and the digestion products of the proteins. An excellent bibliography is given at the end of each section. The authors are to be commended, as the material is well chosen, maintaining the high character of the previous editions. The book should prove useful as a work of reference to the chemist in general and helpful to those working in the realm of laboratory medicine.

Naissance vie et mort des maladies infectieuses. Par Charles Nicolle, directeur de l'Institut Pasteur de Tunis. Paper. Price, 15 francs. Pp. 218. Paris: Felix Alcan, 1930.

Charles Nicolle is a great investigator in the field of infectious diseases. In 1928 he was awarded the Nobel prize in medicine for his work on typhus fever. He played a decisive part in the demonstration of the value of convalescent serum, notably in typhus. In this book, which is one of a series on various scientific subjects, are discussed fundamental questions of a general nature and of general interest concerning the evolution of infectious diseases. The preliminary chapter deals with the infectious microbes and their modes of action. Then follow chapters on (1) the life and characteristics of the infectious diseases as seen in the individual and in epidemics; (2) on the birth or development of infectious diseases, and (3) on the death or disappearance of these diseases as the result of the spontaneous workings of natural forces and of human efforts. The discussion is along rather broad lines. Facts, theories and speculations are presented lucidly without any undue claims of finality for the conclusions that are advanced tentatively. Contrary to the results of recent historical studies, the so-called American origin of syphilis is taken for granted without question. The book will interest educated persons and to physicians and medical workers it will be a stimulus toward a clearer understanding of infectious diseases in their broader biologic aspects.

Physiological Principles in Treatment. By W. Langdon Brown, M.A., M.D., F.R.C.P., Physician to St. Bartholomew's Hospital. With the collaboration of R. Hilton, M.A., M.B., M.R.C.P., Assistant Physician and Assistant Director of the Medical Unit, St. Bartholomew's Hospital. Cloth. Price, $3.75 net. Pp. 464. New York: William Wood & Company, 1930.

In this age of progressively accelerated progress, books of this kind are a necessity; and every practicing physician owes it to himself and his patients to keep his concepts on physiology from growing stale by reading a book like this once every few years. Even the young physician, out of medical school but a few years, will be surprised at the rapidity with which physiology is outgrowing his notions acquired in school. The perusal of this book makes one wish for the time to return when clinicians were teachers of physiology. Courses on pure physiology given by nonmedical men should be relegated to the premedical studies. A vigorous course on applied physiology should be an essential factor of every medical course worthy of its name: for the practice of medicine is largely applied physiology. In therapeutic suggestions, this book is a veritable gold mine. Here are a few of the nuggets: "The administration of thyroid extract diminishes the amount of bile salts in the urine with great relief of pruritus" in cases of jaundice. "In hematemesis . . . I place considerable reliance on half drachm doses of the 1:1,000 solution of adrenalin chloride in half an ounce of water every three to four hours. In addition to constricting the bleeding point it stops peristalsis." "It will often check vomiting or hiccup in doses of 10 to 15 minims of a 1:1,000 solution diluted with water. I have found this most useful in combination with 1 minim of carbolic acid and 3 minims of dilute hydrocyanic acid." "Corpus luteum hormone . . . inhibits ovarian secretion between oestra and particularly during pregnancy. . . . We have seen it successfully used in the prevention of habitual abortion." "In hypochlorhydria . . . the combined use of alkalis before meals, followed after meals by a good dose of dilute hydrochloric or nitrohydrochloric acid with nux vomica, has given me more satisfactory results than either separately. And we should not be niggardly; for even the full pharmacopeial dose of 20 minims would only confer an acidity of 0.02 per cent on a pint of fluid. . . . In complete achlorhydria up to a drachm of dilute hydrochloric acid in a half pint of lemonade or orangeade should be given during meals." "Fifteen grains of calcium lactate three times a day in water should control functional albuminuria." "Lactose in doses of from 2 to 4 drachms three times a day in hot water before meals often achives the same end as *Bacillus acidophilus* and may do away with the need for aperients. As to the selection of cases, the treatment can only be expected to be beneficial where there is definite evidence of increased putrefaction of proteins. The reaction of the feces will be a guide; if they are acid, this treatment is unsuitable; if they are alkaline at first, but yield a fair quantity of gas in the fermentation tube, showing an acid reaction after, the treatment will probably be unsuccessful. Good results can only be expected in cases where the fresh feces are alkaline and remain alkaline after twenty-four hours, yielding hardly any gas to the fermentation tube."

Die zentrale Abstimmung der Sehsphäre. Von Dr. Hans Hoff, *Abteilungsassistent der Klinik. Paper. Price, 7.50 marks. Pp. 96, with* 7 illustrations. Berlin: S. Karger, 1930.

This short brochure, which is number 54 of the Abhandlung aus der Neurologie, Psychiatrie, Psychologie und ihren Grenzgebieten, deals with clinical, experimental and deductive evidence of the influence of adjacent centers on the visual cortical region. There are ten chapters which vary from the influence of sleep on vision and vice versa to a consideration of the genesis of optical hallucinations. Seventeen cases are used to illustrate various points and, most remarkable to state, not once is there a dream analysis based on sex stuff. The deductions from the experimental work seem somewhat exaggerated to the clinician, for the analysis of subjective canine functions depends for the greatest extent on the analyzer and not the canine. Again, some of the analyses of the so-called visual field scotoma, lead an ophthalmologist to believe that the author would be a help in developing the account of a piscatorial excursion into the northern woods (vide page 28). The concluding chapter, which deals with the psychophysical variations in the functional regions of the occipital cortex, is well worth while.

Medicolegal

Lumbago or Sacro-Iliac Strain

(Taylor v. Southern Engineering Const. Co. (La.), 125 So. 877)

Taylor was working on a pile driver, in the construction of a bridge. He accidentally fell from 15 to 25 feet into the water, striking on his back, swam and waded out of the stream, and walked several hundred yards to the tent where he slept. He went home the following day, after doing a day's work. There he was confined to his bed for two weeks or more and partly confined there for three or four months. Prior to the fall, the patient had been engaged in heavy manual labor and had not complained of his back. After the accident and up to the time of the trial, nearly eighteen months, the patient worked only two days immediately following the accident and about five and one-half days on another job. He had to give up the latter work because it caused him so much pain.

The patient's employer, the Southern Engineering Construction Company, the defendant in this case, paid compensation under the employers' liability act from the date of the accident up to June 18, 1928, but paid nothing thereafter. The patient thereupon brought suit, claiming compensation for total disability. In the Eighth Judicial District Court, Parish of Grant, judgment was given in the patient's favor. His employer then appealed to the Court of Appeal of Louisiana, Second Circuit.

Dr. J. I. Peters, who examined the patient for the employer's insurer, testified in the course of the trial that in January, 1929, he was led by an examination of the patient and reports of inspectors to believe that the plaintiff was faking injury. He examined the patient again in June, 1929, assisted by Dr. D. C. McBride, and the roentgen ray showed no evidence of injury. If the patient was then suffering from pain, it was plainly caused by lumbago, "due to other pathological causes quite as much, if not more, than the injury." Dr. Peters based this conclusion on the roentgen examination, which showed an anomaly of the spine, together with the fact that the patient had sources of septic infection, diseased tonsils and teeth. The witness would not say that it was impossible for a patient to suffer a severe sprain of the sacro-iliac joint, sufficient to incapacitate him, without there being some bony injury, or some separation of bony relations, or some callus formation from bony injury, discoverable later by the roentgen ray, but he thought it improbable that such an injury could exist without some of these conditions being discoverable.

Dr. D. C. McBride, who assisted Dr. Peters in his second examination, in June, 1929, testified that the examination showed some stiffness in the lower part of the patient's back and that the patient complained of pain over the sacro-iliac region and the crest of the ilium. He manifested some difficulty in completely flexing or extending the thighs and was limited in flexion, extension and rotation of his spine. Dr. McBride concluded that the patient was suffering from some impairment in the sacro-iliac region, but he believed the trouble was due to absorption from some source of infection and that the plaintiff's teeth and tonsils could cause the trouble. He found no evidence of injury. The anomalous condition of the patient's vertebra may have exaggerated conditions. The fall may have been the beginning of the trouble, which the points of infection continued. It was probable that the patient's injury had something to do with his present condition. Any part that is injured, especially joints, tends to be a point of infection. Dr. McBride thought that the patient would be able to do hard manual labor, if his tonsils and teeth were removed.

Dr. Rand testified that the patient had a definite sacro-iliac strain; it would have been remarkable for the plaintiff to have described the symptoms if he had not had them. A roentgen examination would not necessarily show such an injury as the patient complained of, because of the peculiar, irregular-shaped joint; the plane between the sacrum and the ilium is not a flat surface but is curved. Dr. Rand had had patients in whom the roentgen ray indicated a normal condition, notwithstanding the fact that there was a strain of the sacro-iliac joint.

Dr. M. Cappel had examined the patient twice. The roentgen examination showed an abnormal formation of the sixth [sic] lumbar vertebra, and a back so formed was more susceptible to injury than a normal back. A person, Dr. Cappel testified, can sustain a severe injury to the muscles, ligaments and nerves of the back, without a roentgen examination showing it. He was positive that the patient was suffering from a sacro-iliac sprain. The patient, according to Dr. Cappel, was not suffering from bad tonsils or bad teeth. He was suffering from a disability that made it painful to perform manual labor.

The Court of Appeal pointed out that while Dr. Peters and Dr. McBride, who examined the patient on behalf of the employer's insurer, contended that the patient's trouble was due to his infected teeth and tonsils, they were not willing to say that the injury received by the patient when he fell was not a contributing factor to his present condition, and the court added:

> "The compensation paid injured workmen under the compensation staute is based upon disability and it is immaterial whether the injury alone, or in conjunction with a latent systemic infection, caused the disability."—*Womack v. New Orleans Public Service, Inc., 5 La. App. 71.*

Dr. Peters and Dr. Meyers and other doctors who testified for the employer, said the Court of Appeal, contended that a sprain as severe as the one claimed by the plaintiff almost always causes a widening of the bony relation, or other bony injury, that will be shown by the roentgen ray. But Dr. Cappel and other physicians who testified for the patient denied that statement and cited cases they had treated in which the injury of the sacro-iliac joint was so severe as to cause total disability for several years and in which the roentgen ray showed nothing. Positive testimony will prevail over negative. When a physician, testifying as a medical expert, gives his professional *opinion to the effect that a sprain of the sacro-iliac joint, severe enough to cause total disability, will not necessarily* cause a widening of the bony relations or other bone injury sufficient to show in roentgenograms and declares that he is treating numerous cases of that kind in which nothing is shown by the roentgen ray, his testimony must prevail over that of another medical expert who expresses the opinion that such a sprain will always show in the roentgen picture.

The patient in this case, concluded the Court of Appeal, is a man of average ability and learning. He has never performed any work other than manual labor and is totally disabled for such work. He therefore comes under the total disability clause of the workmen's compensation law. The judgment of the district court was therefore amended by increasing the amount allowed the patient so as to compensate him on the basis of total disability, and the judgment as thus amended was affirmed.

Society Proceedings

COMING MEETINGS

American Academy of Ophthalmology and Otolaryngology, Chicago, October 27-31. Dr. W. P. Wherry, Medical Arts Building, Omaha, Secretary.

American Academy of Physical Therapy, Boston, November 12-14. Dr. Thomas L. Smyth, 111 North Eighth Street, Allentown, Pa., Secretary.

American Association of Railway Surgeons, Chicago, November 5-7. Dr. Louis J. Mitchell, 29 East Madison Street, Chicago, Secretary.

American Public Health Association, Fort Worth, Texas, October 27-31. Mr. Homer N. Calver, 370 Seventh Avenue, New York, Executive Secretary.

Central States Pediatric Society, Memphis, Tenn., November 7-8. Dr. A. H. Parmelee, 310 South Michigan Boulevard, Chicago, Secretary.

Medical and Surgical Association of the Southwest, El Paso, Texas, November 6-8. Dr. W. Warner Watkins, Box 1587, Phoenix, Ariz., Secretary.

Radiological Society of North America, Los Angeles, December 1-5. Dr. I. S. Trostler, 25 East Washington Street, Chicago, Secretary.

Southern Medical Association, Louisville, Ky., November 11-14. Mr. C. P. Loranz, Empire Building, Birmingham, Ala., Secretary.

Southern Surgical Association, Lexington, Ky., December 9-12. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.

Western Surgical Association, Kansas City, Mo., December 5-6. Dr. Frank R. Teachenor, 306 E. Twelfth St., Kansas City, Mo., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Subphrenic Abscess. Gatewood, Chicago.—p. 398.
*Remote Symptoms of Unrecognized Thyroid Adenomata. P. K. Gilman and W. E. Kay, San Francisco.—p. 405.
*Anorexia Nervosa, Anorexia, Inanition and Low Basal Metabolic Rate. J. M. Berkman, Rochester, Minn.—p. 411.

Relationship of Achylia Gastrica to Pernicious Anemia.—Experiments were performed by Castle et al. to test the validity of the hypothesis that the genesis of the disease pernicious anemia is dependent on an inadequate gastric digestion of protein, thus permitting the development of a virtual deficiency in the presence of a diet adequate for the normal individual. They conclude that the active constituent (intrinsic factor) of the normal human fasting gastric contents is in all probability secreted by the mucosa of the stomach and is not detectably present in normal saliva or duodenal contents free from gastric juice, or in the secretions of any portion of the gastro-intestinal tract of the patient having pernicious anemia. This substance is probably organic, thermolabile, possibly an enzyme, capable of interaction with protein (extrinsic factor) or closely related substances in neutral solution, resulting in the production of material having, when administered to patients with pernicious anemia, a marked hematopoietic effect. If an enzyme, it is certainly not pepsin; its properties as so far determined are only in certain respects similar to those of rennin. The lack of this particular property (intrinsic factor) of the gastric contents in pernicious anemia is probably the essential defect leading to the development of the disease, through a failure of the normal reaction, occurring in these experiments with beef muscle proteins (extrinsic factor, and normal human gastric juice. It is also concluded that the existing tests for hydrochloric acid and pepsin of the gastric juice are not necessarily of value in determining the presence or absence of the intrinsic factor essential to the reactions between normal human gastric juice and beef muscle described in these papers.

Normal Filament and Nonfilament Polymorphonuclear Neutrophil Count.—Farley et al. are of the opinion that the most delicate method of studying the reaction of the bone marrow in infections of all types is the estimation of the young forms of polymorphonuclear neutrophils. This is in agreement with others. It is especially valuable in the diagnosis of cryptic infections of subacute or chronic types in which there is no increase in the total leukocyte count. It may add additional presumptive evidence in cases of malingering and hysteria masquerading as organic disease. Its value in prognosis is yet to be established. In profoundly toxic cases with a normal total count or a leukopenia, the agonized efforts of the bone marrow can be determined only by study of the character of the nucleus of the leukocyte. Their method is the differentiation of 100 consecutive leukocytes to determine thus the percentage of nonfilament neutrophils, filament neutrophils, lymphocytes, monocytes, eosinophils and basophils, in which Cooke's criterion is used to separate the polymorphonuclear neutrophils into old and young groups. This method is recommended especially for routine clinical examinations and not in competition with the more complex methods available to expert hematologists. The authors have found by this method that the upper limit of a normal young polymorphonuclear leukocyte (nonfilament) count is in the neighborhood of 16 per cent of cells. The average count in 190 presumably normal adults was approximately 8 per cent. An increased percentage of young polymorphonuclear leukocytes may indicate the existence of infection, even though the total number of leukocytes is not increased.

Diagnosis of Pneumococcus Peritonitis from Blood Picture.—In pneumococcic peritonitis, Gibson regards the characteristic picture of an extraordinarily high leukocyte count with high percentage of polymorphonuclears as a valuable point in differential diagnosis from appendical and other nonpneumococcic forms of peritonitis.

Digitalis Therapy in Lobar Pneumonia.—Two years of observation in hundreds of cases has convinced Niles and Wyckoff that the results obtained do not justify continuing the routine administration of digitalis to patients suffering with lobar pneumonia.

Barium Chloride in Stokes-Adams Syndrome of Complete Heart Block.—Parsonnet and Hyman report on their experiences with barium chloride in doses of from 0.04 to 0.6 Gm. daily in eight cases of auricular and ventricular dissociation exhibiting the Stokes-Adams syndrome. In no case did the barium exert any influence, either good or bad, on the frequency or severity of the seizures, nor was the progress of the myocardial changes altered. In one case barium was administered 126 days and in no case less than 40 days. The total amount of barium taken all together varied from 9.6 to 40.32 Gm.

Uninfected Mural Thrombi of Heart.—Harvey and Levine reviewed 2,091 necropsy records. The incidence of thrombi of the heart was found to be approximately 5.3 per cent, or 111 instances. The frequency of thrombi was slightly greater in the auricles than in the ventricles. The two most common sites of thrombus formation were the tip of the left ventricle and the right auricular appendix. This was true for both isolated and multiple thrombi. Thrombi were found to be slightly more frequent on the left side of the heart than on the right (87 to 72). In analyzing the condition in the auricles and the ventricles separately, however, there was a great predominance in the right auricle as compared to the left (60 to 28) and in the left ventricle as compared to the right (59 to 12). It is apparent from a study of the pathologic finding in these cases that the sequence of coronary artery disease, cardiac infarction and mural thrombosis of the ventricles is the most common mechanism of the production of thrombi in the chambers of the heart. Cardiac mural thrombi were twice as frequent in males as in females. The majority of these patients died between the ages of 40 and 70 years. The patients with ventricular thrombi following cardiac infarction formed the oldest age group (62 years). There was a large middle-aged group with valvular disease (45 years). Secondary infarction outside the heart as a result of emboli occurred with the following frequency: pulmonary, 47; renal, 18; splenic, 12; cerebral, 3 (the brain was examined in only a limited number of instances). There were six instances of peripheral arterial thrombosis that may have been embolic. Auricular fibrillation definitely increases the incidence of auricular thrombosis. The two most frequent mechanisms for the formation of cardiac mural thrombi are the myocardial degeneration associated with coronary arterial disease and the improper functioning of the auricles leading to blood stasis. The diagnosis of cardiac mural thrombosis presents difficulties but should be suspected in cases of coronary thrombosis and chronic valvular disease showing evidence of emboli.

Production of Hypertrophic Arthritis by Interference with Blood Supply.—Experiments are reported by Goldhaft et al. in which the phenomena of arthritis, chiefly of the hypertrophic variety, are brought about in the region of the patella of dogs by ligation of the blood supply to the patella. Control experiments in which an amount of silk ligature equal to that used in the original experiments was placed around the patella, following on an otherwise essentially identical operation, failed to produce any overgrowth after a comparable lapse of time. Analyses of the overgrowth and of the original patella giving rise to the overgrowth show that the percentage magnesium content in these tissues is higher than on the control side. The involvement of the mineral metabolism in the region affected is thus clearly indicated. These experiments are in entire consonance with those arrived at, following a different line of reasoning, by Wollenberg and indicate beyond any reasonable doubt that disturbance of the blood supply must henceforth be regarded as one of the factors capable of producing arthritic change. Taken in conjunction with other work, these experiments afford strong evidence that interference with the blood supply, probably in the nature of vasoconstriction, constitutes at least a part, probably a large part, of the underlying physiologic disturbance productive of the phenomena of chronic arthritis, especially the hypertrophic type as encountered in human beings.

Subphrenic Abscess.—A review of the literature by Gatewood and of forty-one cases observed in the Presbyterian Hospital during the past ten years shows that the mortality in subphrenic abscess is still much too high, being 30 per cent or more. In spite of improved diagnosis methods and earlier operation, acute appendicitis ranks high as an etiologic factor—second in this series. The importance of prophylactic treatment cannot be overemphasized. Early diagnosis of appendical and other contributory causes and their prompt elimination will prevent the formation of many subphrenic abscesses. Adequate drainage and the adoption of the semisitting posture in all lower abdominal infections are two most important preventive measures that should not be forgotten. Finally, attention is again called to the failure to consider the likelihood of subphrenic abscess in any patient not doing well after an abdominal operation, even though performed months previously.

Remote Symptoms of Unrecognized Thyroid Adenomas.—In the thirteen cases reported by Gilman and Kay, the classic signs of thyroid toxicity were for the most part absent. Furthermore, the basal metabolic rate in each instance was either normal or below normal. In many instances the patients were more or less indefinite in their complaints but were unanimous in stating that they did not feel well and knew that something was definitely wrong. Their symptoms largely directed attention away from the thyroid gland and suggested trouble with systems elsewhere in the body. Nervousness was the most frequent symptom. This nervousness was not suggestive of the type usually seen in thyrotoxicosis. It was in the nature of a nervous tension and sense of apprehension, associated with a feeling of carrying too heavy a load. As a rule this symptom was brought out only after careful questioning, thus differing from the objective nervousness usual in hyperthyroidism. Several of these patients had been classified as psychoneurotic, chiefly of the neurasthenic type. Weakness, fatigability and palpitation were common symptoms and present in nearly all the cases. These, with shortness of breath, had evidently led to a previous diagnosis of cardiovascular disease in nearly half of these patients. Five of the thirteen patients exhibited a definite hypertension, three showing a high diastolic pressure and cardiovascular damage. The other two showed definite heart and blood vessel changes but to a lesser degree. Attention was directed especially to the gastro-intestinal tract in three of the patients. One patient had been previously treated for more than a year for gallbladder disease and colitis; a second case, diagnosed as sprue, had been treated for a chronic enteritis for five years. The third had been under treatment for stomach trouble. One patient had had a chronic cough and had been diagnosed as having pulmonary tuberculosis. Among the less frequent symptoms, loss of weight was present twice; dizziness was complained of twice; tremor of the fingers but once. A feeling of warmth was not complained of in any instance in this series. The pulse rate was usually a little increased but seldom over 80 per minute. In two cases the rate was between 60 and 70 per minute. The authors urge that in such case adenomas of the thyroid must be carefully excluded as the underlying cause. Toxic adenomas are not necessarily accompanied by an increased basal metabolic rate but may be present with a normal or subnormal rate. The improvement these patients exhibited following operation was striking and gratifying.

Anorexia Nervosa, Anorexia, Inanition and Low Basal Metabolic Rate.—According to Berkman, anorexia nervosa constitutes a definite clinical entity. Briefly, its clinical characteristics are anorexia, inanition, emaciation, various gastro-intestinal disturbances, marked nervous manifestations, and low basal metabolic rate. The condition is not common. At the Mayo Clinic, 117 cases were so diagnosed in thirteen years. It seems probable that the low basal metabolic rate is the result of inanition. The absence of any demonstrable pathologic change characterizes the condition as a physiologic disorder secondary to a psychic disturbance. The reestablishment of normal intake of calories is the direct goal, and to this end treatment with a preparation of thyroid gland has been proved to be a valuable adjunctive measure. A similar condition due to inanition may be found in some cases in the absence of anorexia.

*Value and Place of Radium in Treatment of Diseases of Thyroid Gland. S. Ginsburg, New York.—p. 283.
Barium Enema Entering Esophagus: Case. C. G. Lyons, Hines, Ill.—p. 300.

Bone Lesions in Tardive Heredosyphilis.—Pendergrass et al. report the case of a man who had almost every possible type of bone involvement found in syphilis, all of which responded to treatment. Cutaneous manifestations, and involvement of the liver and spleen were interesting complications. The patient responded to antisyphilitic therapy and the change produced in the bones is described.

Menstrual Headaches.—Martin asserts that one type of menstrual headache, characterized by pain in the occipital or frontal regions, and nausea and vomiting, and relieved during pregnancy, probably has an endocrine origin. This type of headache may be partially or completely relieved in a certain number of women past the age of 40 by the production of an artificial menopause with irradiation. The use of castration in younger women seems of doubtful value and may even accentuate the symptoms.

Radium in Treatment of Toxic Goiter.—Reviewing the results achieved with radium in the treatment of hyperthyroidism, including the diffuse exophthalmic type as well as that associated with adenoma, Loucks says that they parallel those obtained with surgery; the type of case that responds poorly to irradiation is identical with that which requires two or more thyroid operations. Radium therapy accomplishes a marked restoration of sugar tolerance in cases associated with glycosuria, indicating a complete control of the hyperactive thyroid. The primary mortality is nil; preoperative and postoperative morbidity is eliminated; from the standpoint of the period of disability, hospital expenses and the concomitant loss of wage-earning power, radium holds a tremendous economic advantage over any other therapeutic procedure.

Radium in Treatment of Diseases of Thyroid Gland.—Ginsburg ardently advocates the use of radium in the treatment of benign and malignant diseases of the thyroid. It effects more cures and has a much lower mortality than surgery. In exophthalmic goiter, clinical cure of a lasting kind has been obtained not only by implanting radium interstitially into the thyroid gland but also by external application of properly screened radium. Radium therapy, efficiently used, relieves not only the toxic but also the compression phenomena in toxic adenomatous goiter, or toxic adenoma of the thyroid. Radical surgery has failed to produce permanent cure of thyroid cancer even when the operation was performed in the so-called early stage of the disease. The end-results of surgery in thyroid cancer would justify the method only in the absence of any superior method.

Influence of Hyperthyroidism on Secretion of Free Hydrochloric Acid.—In Brown's opinion the symptoms of hyperthyroidism can be interpreted in terms of an increased sympathetic drive due to the action of the altered thyroid hormone causing an oversensitization of the thoracicolumbar sympathetic system which overrides the normal antagonistic moderator action of the parasympathetic. The drive is present with varying intensity in the different portions of the sympathetic system and the relative preponderance of ocular, cardiac or gastric symptoms depends on the degree to which the various parts of the sympathetic mechanism are affected by the altered thyroid secretion. Interpreted in terms of the secretion of free hydrochloric acid, the increased sympathetic drive causes a stimulation of the inhibitory acid-secreting fibers of the gastric mucosa and results in a diminution or lack of secretion of acid.

Cardiac Arrest.—Green feels that the occurrence of cardiac arrest is perhaps more frequent than physicians are inclined to think. It may be the cause of death in a large majority of the cases that occur on the operating table, whether it is primarily a cardiac failure or cardiac failure secondary to vasomotor relaxation. Primary cardiac arrest can be combated successfully by cardiac massage. Cardiac arrest secondary to vasomotor relaxation can be prevented by preserving the vasomotor tone during the operation and combated by raising the intracoronary tone through intra-arterial injections of fluid followed by intravenous injections of fluid. In this type of arrest, direct cardiac massage may also be of great value. The success of the issue depends, to a large extent, on the preparedness of the operating room to combat such an eventuality.

Chordotomy for Intractable Pelvic Pain.—Beck's patient had sustained a crushed pelvis and a rupture of the bladder. The left ilium, both ischia and the left pubis were fractured. The left transverse process of the fifth lumbar vertebra was also fractured. The patient suffered considerable pain of a dull, boring, constant nature, localized almost entirely between the costal margin on the left and the lower part of the pelvis. In view of the localization of the pain almost entirely to the left side, it was thought that section of the pain fibers on the right side of the cord would give relief. Laminectomy was carried out over the fourth, fifth and sixth thoracic vertebrae. The dentate ligament on the right side of the spinal cord was picked up in a small clamp and the cord rotated to the opposite side. This exposed the anterolateral tract on the right side. The point of a scalpel was inserted just anterior to the dental ligament to a depth of 3.5 mm. and carried forward for about the same distance. The area of anesthesia on the left side of the body was then determined and it was found to be adequate. The operative wound was sutured. The patient immediately felt relieved of the former pain. Convalescence was uneventful. The area rendered anesthetic to pin-point pain extended from the costal margin on the left downward over the pelvis and left leg. The sensation of heat and cold was lost over this area. The sensation of light touch was preserved. The reflexes were normal. The sense of position and the vibratory sense were normal. There was no motor involvement and there was no difficulty in urination.

Results of Subtotal Gastrectomy for Gastric and Duodenal Ulcer.—In 401 primary subtotal gastrectomies for ulcer of the stomach below the cardia or in the duodenum, Berg reports 6.9 per cent mortality. This mortality includes every death following primary subtotal gastrectomy during six years of ward and five years of private service. It includes all bleeding ulcers, active or arrested, all patients with chronic pulmonary lesions, all patients with chronic cardiovascular disease, all patients with tetany and all patients with chronic renal lesions. He has not seen any case of pernicious anemia following partial gastrectomy. He describes his technic in detail. He also calls attention to several important facts concerning ulcer. First, ulcer of the stomach and duodenum is a local disease dependent on a specific gastritis, free hydrochloric acid in the stomach contents, and a secondary infection. Second, a radical cure must eliminate all of these factors. Third, experience has shown that partial gastrectomy, because it eliminates all these factors, is most likely to effect a radical cure. The number of recurrences after partial gastrectomy is exceedingly small—about 1 per cent. Investigation has shown that the medical treatment of ulcer is attended by just as grave risks as is surgical treatment, and, unless instituted early, is not likely to bring about radical cure; and that when a patient has had one or two good medical treatments and has not been cured, operative procedure should be undertaken.

End-Results in Cholecystectomy.—Of 352 cases accounted for by Sanders, 269 were completely relieved of the symptoms for which the operations were performed. Forty-two patients reported only partial relief but were improved. Only fourteen were not benefited. The digestion was greatly improved in 306 cases. Only partial relief was obtained in thirty-three cases. Thirteen of the entire group were not relieved or were made worse. The condition of the wound was satisfactory in 91.5 per cent of the cases, whereas a bulge or hernia occurred in thirty (8.5 per cent) of the entire group. The incidence of postoperative hernia was far greater in cases in which the wounds were drained than in cases in which they were not drained. Practically all the hernias that occurred were in the cases in which operation had been done through an upper right rectus incision with the rectus muscle retracted to the outer side. After the operation, 87.2 per cent of the patients did not have colic, whereas 12.5 per cent reported having had one or more spells of "bilious" colic. The pain was similar to the former spells and in practically all cases the patients were afraid of the return of the original trouble. After the colic had subsided there was no jaundice in most cases and the progress was then as smooth as it was in the uncomplicated cases. In two cases, stones were later found in the common bile duct and a secondary operation was necessary. In the remaining number it was not possible to determine the cause of recurrent pain in the absence of any apparent unremoved lesion. Sixteen patients (4.5 per cent) reported the appearance of postoperative jaundice of some degree. This could be accounted for in two cases by the finding of stones in the common bile duct, but in the others the cause was less certain. The icterus soon disappeared and did not leave any bad after-effect.

Surgical Treatment of Urinary Incontinence in Women.—Smith states that a careful plastic repair of the anterior vaginal wall with such other gynecologic procedures as may be indicated will correct the impaired bladder control of which many of these sufferers complain in the majority of instances. When the incontinence is more pronounced, the Kelly operation of tightening the vesical sphincter combined with colporrhaphy gives a cure in a considerable proportion of women with relaxed vesical sphincter. When this procedure failed in a case of severe incontinence, the addition of bladder drainage to the plastic procedure on the sphincteric region supplemented by an interposition gave an excellent result.

Noneffect of Viosterol in Treatment of Fractures.—In seventeen cases of various fractures in adults, most of them fractures of the shafts of the long bones, Lewis studied the effect of viosterol on healing. There was no hastening of union or callus formation. The calcium and inorganic phosphorus in the blood was not materially raised. An average rise of only 1.4 mg. of calcium was obtained and the phosphorus showed relatively no change. Delayed union was present in six cases and no benefit was obtained by using viosterol.

Malignant Tumors and Their Metastases.—A summary of the necropsies in 865 cases of malignant tumor is presented by McWhorter and Cloud. Ninety-five of these were cases of sarcoma, none of which showed any metastases. Among the 770 cases of carcinoma, 187 showed metastases. They were present most often in cases of carcinoma of the esophagus, stomach, large intestine, bladder and liver, the two last named having the highest number (29.17 and 39.19, respectively); only thirty-two of 208 stomach cases showed metastases. No metastases were found in the small intestine, ovary, testicle, thymus, melanoma and tooth bud cases, a total of twenty-three cases. The average age for all malignant tumors at necropsy was 51. Excepting in the very aged, age does not seem to influence metastases. In the aged, the neoplasm was usually of local growth. About 69 per cent of the malignant epithelial tumors arising in, or from, the skin and mucous membrane remained local in their growth, invading either the neighboring lymph glands and adjacent tissues or both, while only 28 per cent of the cases arising in glandular organs showed the same local tendency of growth. One of the interesting observations in this review was the number of cases that showed only local invasion of the neighboring tissues and adjacent lymph nodes. Perhaps of even greater interest are the cases in which the neighboring nodes were alone involved. This held true for *carcinomas regardless of their site of origin*, but were much more frequently found in the cases whose site of origin was the stomach, large intestine, urinary bladder and cervix. The most interesting feature of this series is the number of cases of supposedly malignant tumors that did not metastasize. Out of 770 morphologically malignant epithelial neoplasms, 187 showed no obvious evidence of metastases. It is suggested that virulence and body resistance may be the guiding factors in the growth of all malignant neoplasms, as they seem to be in all infections.

Progress in Psychiatry: IV. Experimental Type Psychology. F. Wertham, Baltimore.—p. 605.

Incidence of Fever and Leukocytosis in Multiple Sclerosis.—The study of 109 records of reasonably certain cases of multiple sclerosis is reported by McKenna with reference to the reactive changes in temperature, leukocyte count and examination of the cerebrospinal fluid. Neither fever nor leukocytosis was shown by 40.4 per cent, but three showed increased cell counts in the cerebrospinal fluid. Elevations in temperature were shown by 55.9 per cent, 44.9 per cent between 99 and 99.5 F. and 11 per cent between 99.6 and 100 F. Definite leukocytosis was shown by 22.9 per cent, 3.6 per cent occurring without elevation in temperature and 19.3 per cent accompanying febrile reactions. Pleocytosis of the cerebrospinal fluid occurred in nineteen cases, or 17.4 per cent; three of these cases showed normal temperatures and leukocyte counts; seven were accompanied by fever alone; two by leukocytosis alone, and seven by both fever and leukocytosis.

Galactose Tolerance in Dementia Praecox.—The galactose tolerance was determined by Sleeper and Hoskins one or more times in 135 cases of dementia praecox. The tolerance level was constant in 15 and variable in 24 of the 39 cases in which multiple determinations were made. Similar variability has been noted by others in the blood sugar curves following the ingestion of dextrose. In the series as a whole there was a downward trend of the galactose tolerance, averaging approximately 15 per cent. In 8 per cent of the subjects the tolerance was above normal, and in 58 per cent it was below normal. The catatonic group showed the highest incidence of normal tolerance and the lowest incidence of depressed tolerance. The hebephrenic group showed the lowest incidence of normal tolerance and the highest incidence of lowered tolerance. The galactose tolerance test appears to have some value in the differential diagnosis of the two types. No relationship between weight, age, creatinine output, protein catabolism or initial blood sugar level and galactose tolerance could be detected. There was some evidence of a decrease of tolerance with the increase of the period of hospitalization. A tendency to lowered tolerance for galactose is added to the list of characteristics of dementia praecox that indicate a depression of functions under endocrine or autonomic control.

Pneumobacillus Meningitis Secondary to Otitis Media.—Malis points out that, clinically and pathologically, septic leptomeningitis due to the pneumobacillus resembles in every way the fulminating type due to the pneumococcus; while cases due to the latter end fatally, those due to the pneumobacillus, if checked early, may be cured. It is therefore of importance to differentiate these two organisms.

Adenoid Cystic Carcinoma.—Although there are well authenticated but rare cases in the literature in which ordinary basal cell carcinomas have extended to the regional lymph nodes, Spies failed to find instances in which there were any proved distant or generalized metastases. That such widespread dissemination may occur is believed to be reported here for the first time. Three cases are cited. It is this feature that Spies particularly wishes to emphasize.

Relationship Between Nerve Plexuses and Lymph Nodes of Abdomen.—Kiss asserts that the abdominal lymph nodes lie in close topographic connection with the ganglions and nerve plexuses. Pathologic changes in the lymph nodes, such as hyperemia and enlargement, may cause various nervous symptoms, such as irritation and paresis. The ordinary operative removal of diseased lymph nodes may result in various injuries to the nerves and ganglions. This explains various postoperative complications after such operative procedures.

Osteogenic Sarcoma of Humerus.—The history of a case of telangiectatic osteogenic sarcoma of the humerus is presented by Morton and the recent literature on osteogenic sarcoma briefly reviewed. The principal features of the case were the extreme rapidity of growth of the tumor and the immense size attained by it. Only four months elapsed between the time of the onset of the first symptoms and the death of the patient. The case is discussed briefly from the standpoint of the pathology, diagnosis and treatment.

Ureterocele.—Two cases are reported by Dawley. In neither of these cases was a positive diagnosis made by cystoscopy. Although ureterocele was considered in each, neither presented the usual appearance of ureterocele at cystoscopic examination; the intermittent ballooning and translucence were absent. The etiology is not clear in either case. In one case, the condition was associated with a congenital anomaly of the urinary tract. In both cases, in all probability, the condition had been present for a longer time than the duration of severe symptoms, which in the first case evidently were due to superimposed infection and in the second to obstruction at both ureteral and urethral orifices. Pyuria had been a persistent symptom in both cases. The radical method of treatment was deemed advisable in view of the infected functionless kidneys and the associated pathologic changes in the ureters. In one case, the ureterocele sac was resected transvesically; in the other it was not disturbed.

Changes in Head of Femur After Complete Intracapsular Fracture of Neck.—Fourteen cases form the basis of Santos' study. He says: After complete intracapsular fracture of the neck of the femur, the proximal fragment may either remain alive as a result of nourishment received through the vessels of the ligamentum teres or become necrotic. If efficient reduction and fixation are carried out early and sufficiently long maintained, bony union follows in a high percentage of the cases in which the head remains alive and in a smaller but no inconsiderable percentage of cases in which the head becomes necrotic. If bony union occurs in the presence of necrosis of the proximal fragment, the limb should be protected from weight bearing for many months while creeping substitution of dead head by new bone is taking place. If marked collapse and deformity of the necrotic head should develop, a Whitman reconstruction operation with excision of the head may sometimes be indicated. If nonunion results and the head remains alive, a patient who is a good risk may be operated on by use of an autogenous bone peg or by the Whitman or the Brackett reconstruction method according to the case. In case of nonunion with necrosis of the head, there may be slow invasion of tissue from the round ligament or from adhesions with gradual absorption and partial replacement of the necrotic tissue by living bony elements. However, the proper operative treatment in case of nonunion with necrosis of the proximal fragment appears to be excision of the head and the performance of a Whitman reconstruction operation. By roentgenographic studies, it is usually possible to differentiate between a head that remains alive and one that becomes necrotic because of the difference in density which develops during the period of disuse and because of the difference in internal structure and occasionally in contour which develops during the period of reconstruction.

Manner of Anastomosis of Hepatic and Portal Circulations. J. M. Olds *and E. S. Stafford, Baltimore.—p. 176.*

Prognosis for Epidemic Encephalitis in Children.—A series of sixty-six children was investigated by Howe at periods varying from one to ten years after the onset of epidemic encephalitis. Immediate mortality based on all hospital admissions since 1918 was found to be 11 per cent. Complete incapacity was found in 19 per cent, partial incapacity in 22 per cent, and recovery in 42 per cent. The acute illnesses were divided into three groups: 1. Somatic (56 per cent of the cases), characterized by paralyses or excitation of the somatic or cranial nerves. 2. Meningeal (16 per cent), in which signs of meningeal irritation predominated. 3. Abortive (19 per cent), in which no true acute illness of ordinary encephalitic type occurred but the early and frequently unheralded appearance of characteristic progressive sequelae took place, often accompanied by febrile reaction. The immediate mortality was higher in the somatic group and at early ages; recovery was almost invariable in the meningitic form, and the most dreaded sequel, parkinsonism, ensued most frequently after the abortive form. Sequelae were divided into progressive and nonprogressive, the former including hyperactivity (usually of a bizarre type), sleep inversion, personality changes, hyperpnea and tics, (all excitation phenomena), the latter characterized by residuums of the acute illness in the form of paralyses, choreiform movements, emotional instability and mental retardation. The nonprogressive sequelae most frequently followed the general somatic type of acute illness and, with the exception of mental retardation, offered a good prognosis. Progressive sequelae justified an unfavorable outlook and, when present as initial symptoms, concomitant with the acute illness, almost invariably led to parkinsonism. Parkinsonism was further shown to ensue only after a characteristic type of progressive (excitation) sequelae.

Placenta from Case of Malaria.—The study made by Wislocki of the placenta from a case of malaria affords proof that the chorionic syncytium is incapable of phagocytizing an inert suspension of pigment present in the intervillous spaces or of transmitting such particles from mother to fetus. Malarial parasites are present in the placenta in great abundance within the erythrocytes in the intervillous spaces. Malaria induces the accumulation of large numbers of monocytes and lymphocytes in the placental circulation. Of these cells, the monocytes phagocytize, abundantly, pigment released by the activity of the malarial organisms. These phagocytic monocytes do not penetrate the fetal tissues but do enter the masses of fibrin formed on the villi, which are denuded of syncytium at these sites. Typical clasmatocytes are not encountered in the intervillous spaces. The monocytes and lymphocytes which gather in the placenta are brought there from other parts of the maternal body where they are produced. The villi, including their stroma and covering chorionic syncytium, are anatomically normal and not visibly affected by the malarial organisms or their products. Wislocki suggests that it is unlikely that malarial organisms can enter or penetrate the chorionic syncytium, so that the transmission of malaria from mother to fetus occurs rarely, if at all.

Ascending Infection of Kidney and Kidney Pelvis.—Gruber and Rabinovitch present experimental evidence which favors the theory that ascending ureteral infections are a cause of pyelitis.

Conservative Surgery of Bilateral Hydronephrosis.—A patient with bilateral hydronephrosis, a large part of the left kidney being completely destroyed and the right kidney less extensively, was treated by Scholl by repeated pelvic lavages followed by *freeing* of the kidneys from extensive adhesions, partial decapsulation and nephropexy. Two months elapsed between the operations on the two kidneys. The result of this conservative procedure has been highly satisfactory.

Spinal Anesthesia.—Campbell regards spinal anesthesia as being the ideal anesthetic for operations below the diaphragm and of invaluable usefulness in patients suffering from advanced nephropathy. Since the introduction of ephedrine, hypotension is now only a relative contraindication to the application of spinal anesthesia. As with all anesthetics, there are a few rather definite contraindications; the more robust the patient, the less is the anesthetic risk. Untoward immediate postanesthetic sequelae result from temporary bulbar anemia; later post anesthesia sequelae are negligible. In Campbell's series, the ultimate postoperative mortality was 4.4 per cent less in those patients operated on under spinal anesthesia than in those to whom general anesthesia was administered. Of particular interest has been the reduction of the operative mortality following upper urinary tract surgery and prostatectomy.

Infectious Origin of Pernicious Anemia; Relation of Pyelitis to Achlorhydria and Pernicious Anemia.—Blair concludes his review by stating: It seems evident that the actual anemia of pernicious anemia is not due to erythrocyte hemolysis or excessive destruction in the vascular system but is the result of a deficiency in the formation of erythrocytes and that the deficiency is due to a lack of sufficient stroma material required for the formation of the erythrocytes. In pyelitis there is a constant loss of granular leukocytes from the body and the occurrence of pyelitis in pernicious anemia constitutes an insistent demand for granular leukopoiesis. There are certain common relationships between erythrocytes and granular leukocytes: (*a*) They are formed in the same location, in bone marrow, in the adult; (*b*) both erythrocytes formation and granular leukocyte formation are decreased in the relapse of pernicious anemia; (*c*) they exhibit a simultaneous response to liver therapy. It seems probable that the excessive production of leukocytes over a long period exhausts from the body the substance (the specific x factor of liver) necessary to both granular leukocyte and erythrocyte formation and is thus responsible for the anemia and leukopenia. It seems probable that the achlorhydria present in pernicious anemia is the end-result of a chronic mild stimulation of gastric secretion associated with a mild chronic infection (pyelitis, and producing an exhaustion of the secreting mechanism of the stomach from overuse, coupled with an exhaustion from the stomach tissues themselves of the specific x factor present in normal stomach tissues. It would seem that the presence of pyelitis in pernicious anemia gives adequate explanation for the presence of fever, loss of weight, the tendency to remission and relapse, and other symptoms. The prevention of pernicious anemia is therefore the prevention of focal infection and consequent urinary tract infection, the detection and cure of focal infection and urinary tract infection already established, and the preventive or palliative administration of the specific substance found abundantly in liver.

Diet in Gallbladder Diseases.—The following rules are laid down by Einhorn for all gallbladder patients. 1. Meals should be ingested frequently (at not too long intervals), in order to induce a complete emptying of the gallbladder quite often. 2. Each meal should consist of mixtures containing the three principal groups of nutritive materials (proteins, carbohydrates, fats) in the right proportions. Excesses in the quantity of food, also too luxurious meals, should be carefully avoided. Likewise too much spice, too much meat, too much beer or wine are to be guarded against. Attention should be given to procuring daily a thorough evacuation of the bowels. Outdoor sports should be indulged in, and long walks—but not to a degree of overfatigue—should be practiced. Increase of the intake fluids should be encouraged. In gallbladder cases, without jaundice, practically all kinds of ordinary foods, excepting highly indigestible or strongly spiced substances, are permissible. In gallbladder diseases, with jaundice, special attention must be paid with regard to the selection of an appropriate diet. Fats are poorly utilized and should therefore be used with great moderation. The following may be arranged as a daily quantum of foods: 2½ quarts of skimmed milk, 870 calories; 100 Gm. of wheaten bread, 245 calories; 100 Gm. of oatmeal (flour), 338 calories, and 100 Gm. of sugar, 400 calories, to which can be added some fresh fruit and a green vegetable. A little later one or two eggs are added. In order to increase the digestibility of the nutritive material pancreatic ferments are advantageously administered. It is then feasible to make the bill of fare more varied, with much profit to the patient. Malignant diseases of the gallbladder and biliary ducts will have to be treated dietetically in a similar manner as the benign disorders of these organs. At first the diet as outlined will be employed. When, however, the disease has already made greater inroads and the usual foods cannot be handled by the patient, the diet will have to be selected mostly from liquid and semisolid nutriments. Milk, buttermilk, koumiss, gruels, broths, eggnogs, sweet almond milk, fruit juices, and jellies will play a great part. An attempt must always be made to keep the organism from losing too much, but toward the end it is seldom possible to supply adequate nutrition. Everything in the line of feeding must be selected in such a manner that it will give comfort and pleasure to the patient until life is ended.

Acute Yellow Atrophy Associated with Neoarsphenamine Injections.—A case is reported by Bortin of a patient with tertiary syphilis who during a course of mercury and neoarsphenamine developed jaundice and died, with changes in the liver not unlike those of acute yellow atrophy. The probable immediate cause was the injection of neoarsphenamine. The predisposing cause of acute yellow atrophy was the injections of mercury.

Immediate Treatment of Intracranial Injury in New-Born.—A detailed consideration of the symptoms observed in 117 cases of cranial and intracranial injury in the new-born, together with a brief consideration of the immediate treatment of these conditions, is presented by Munro. A first baby that is hypertonic, apathetic, refuses to nurse and has a tense anterior fontanel, an abnormal cry and some respiratory abnormality is presumably suffering from some form of intracranial injury. If the cerebrospinal fluid pressure is higher than normal, this diagnosis is confirmed. A first baby that is pale and flaccid, refuses to nurse and has a respiratory abnormality immediately after delivery is presumably suffering from surgical shock. If the cerebrospinal fluid pressure is less than normal, this diagnosis is confirmed. In the presence of surgical shock, treatment should be reduced to the absolute minimum. In the presence of hemorrhagic disease of the new-born, complicating cranial and intracranial injury, the bleeding and clotting times should be brought to normal before decompressive treatment is begun. All types of cranial and intracranial injury in the new-born are complicated at some time by an increased intracranial pressure. Treatment of this complication never should be omitted. The diagnosis "intracranial hemorrhage of the new-born" should be expanded to include cerebral edema and fracture of the skull and should be stated as "cranial and intracranial injury in the new-born."

Effects of Obstetric Injuries on Nervous System.—The possible effect of obstetric trauma to the nervous system of the new-born is discussed by Byers. Case histories are briefly given illustrating the results of lesions involving the nervous system from peripheral nerves to cerebral hemispheres. Attention is called to a method of treatment that is effective provided there exists an intact nervous pathway from a functionally active cerebral cortex to the muscles.

Significance of Acidophilic Cells in Thyroid Gland.—Warren and Stoller present a summary of the cases in which excised thyroid tissue showed acidophilic cells. From 1923 to 1929 this change was encountered in seventy-five patients, thirteen of whom developed actual or suspected postoperative myxedema. Since less than 20 per cent of patients whose thyroids showed acidophilic cells became myxedematous, the presence of these cells is not of practical prognostic value, although it is perhaps a more definite sign than any other.

Treatment of Carbuncles by Roentgen Ray.—From a study of fifty cases of carbuncle treated with roentgen ray, Light and Sosman conclude that when benefit occurred it lay usually in a hastened necrosis of the lesion, a softening or liquefaction of a carbuncle in the indurated stage. In a few instances the spreading tendencies of the lesions were checked, and healing occurred by drying up and absorption without any extensive drainage of necrotic products. Roentgen therapy was occasionally employed with success following surgical procedures which failed to halt the spread of the carbuncle, and in these the acidity of the infectious process was diminished and the peripheral spread halted. Relief of pain occurred in some instances of cervical carbuncles and, quite strikingly, in most of those of the face. Of the entire series, thirty-four patients were observed to have been improved by roentgen therapy, and sixteen to have received no benefit from this treatment. Thirteen out of fifteen women patients were improved; three fifths of the men, when the site of predilection was the neck, were helped by irradiation. Eight of the nine carbuncles of the face responded excellently, as did most of those of the extremities. The proportionate success of roentgen therapy diminished somewhat with the increasing size of the lesion; 75 per cent of those under 5 cm. diameter were benefited, whereas but 60 per cent of those larger than 9 cm. diameter improved as a result of roentgen ray. Diabetes seemed to have little bearing on the chances of success from irradiation.

Simple Dietetic System for Use in Metabolic Disorders.—Levy's system is based on a key chart in which similar foods have been grouped so that varying quantities have similar distribution of protein, carbohydrate and fat. From this chart, diets of any caloric value or any desired distribution of foodstuffs may be derived. Specimen diets are given.

Home vs. General Hospital Childbirths.—Home and general hospital childbirths are discussed by Van Auken with reference to proper preparations, obstetric emergencies, infections, nursing services, the physicians' and patients' attitude, and the relative financial cost. It is obvious from this article that, except for the possible greater frequency of infection in the general hospital and the limited ability of the nursing service for patients unable to afford a full time nurse, the general hospital is a more advantageous place for a childbirth. Home childbirths are desirable and successful when there are no complications and when the patient does not want the maximum relief from her pain. As it is impossible always to predict complications, general hospital childbirths insure greater safety.

Acidity and Chloride Content of Gastric Juice.—A comparison of the gastric secretory response to a meal of gruel and to one of cream was made by Rudd. A fractional analysis of the gastric contents was carried out and total and neutral chloride and total acidity were estimated in the samples. The total chloride content of the gastric secretion was found to remain approximately constant, while the total acidity and neutral chloride show wide variations. The theory of the formation of neutral chloride by the neutralization of gastric acid by duodenal fluid does not explain these results. It is concluded that the variations in the composition of the gastric contents are due to changes in the amounts of hydrochloric acid and neutral chloride being secreted by the gastric mucosa. In an estimation of the secretory activity of a stomach, the total chloride is the significant quantity.

Copper Sulphate Tellurite Medium for Isolation of Diphtheria Bacilli.—Allison compared the results obtained in the isolation of *C. diphtheriae*, *C. hofmannii* and diphtheroid bacilli from nasal, throat and ear swabs, using Douglas' medium and copper sulphate tellurite serum agar. The results show a well marked difference in the percentages of organisms isolated on the two mediums, the differences in all cases being in favor of the copper sulphate medium. The better results obtained with the copper sulphate medium are believed to be due to its greater selective action for the diphtheria bacillus and organisms of the diphtheroid group, and to the powerful inhibitory action of the copper sulphate on staphylococci, streptococci and other commensal organisms found in the nose, throat and ears. Inhibition of the spread of *B. proteus*, resulting from the presence of copper sulphate in the medium, facilitated isolation of *C. diphtheriae*, when this had proved impossible with other mediums.

Flicker Hemoglobinometer.—The instrument devised by Jenkins consists of two fixed lights and a Simmance-Abady photometer head in a fixed position between them. The brightness is varied by the depth of a glass plunger in a cup containing a colored solution through which the light from one of the lamps passes. A glass cell is placed between the head and the other light and contains the sample to be examined. With a capillary pipet, 0.1 cc. of blood is added to 4.9 cc. of distilled water in a small bottle or flask. The solution is gassed, centrifugated, and estimated in the apparatus after first checking the balancing point of the standard at 40 mm. The reading obtained is read on the graph in terms of percentage in Haldane's scale or any other scale which the observer chooses to use. If preferred, an actual blood standard of 2 per cent CO-hemoglobin prepared by the makers of the Haldane apparatus can be used instead of the artificial standard of cobalt chloride.

Old-Standing Tuberculous Kidney.—Conybeare reports a case of what probably was an instance of spontaneous cure of a tuberculous kidney by its being transformed into an innocuous calcareous mass. The whole of the organ appears to have become replaced by a tuberculous pyonephrosis of enormous dimensions, and the tuberculous caseous material has become so infiltrated with lime salts as to produce a dense shadow to roentgen rays. The ureter of the affected kidney has never been permanently occluded, as evidenced by the shadows in the roentgen film. Inquiries from the patient elicited the fact that from time to time he experienced a sensation "as if a tap had been turned off in the bladder." This was followed by the passage from the urethra of cretaceous material, which the patient described as like tooth-paste in color and consistency. It would appear, therefore, that from time to time some of the caseous material from the kidney was passed in the urine. No tubercle bacilli could be found, and probably the tuberculous process is completely arrested. The acute symptoms with which the patient started a recent illness were presumably due to an exacerbation of his chronic urinary infection preventing satisfactory functioning of his right kidney. The case tends to show that, even when there is high resistance to tuberculous infection, involvement of the kidney may lead to serious consequences as the result of secondary urinary infection; it emphasizes the importance of nephrectomy whenever the condition of the other kidney warrants this step being taken.

Vitamin A Deficiency and Resistance Against Specific Infection.—Experiments made by Lassen showed clearly a pronounced decrease of resistance in rats with symptoms of vitamin A deficiency. Within four days after subcutaneous inoculation with living Breslau bacilli, eight out of nine animals with dietary xerophthalmia died, while eight animals on an adequate diet lived more than thirty-seven days. Necropsy of the control animals reveals that the infection persists in the lymph glands, especially the regional glands, a long time after the general infection has been overcome.

Serum Treatment of Scarlatina.—Wylie reports the results obtained in the treatment of 116 cases of scarlet fever with a commercial concentrated antitoxin. The patients came from all types of homes and represented all grades in the social scale. The medical treatment was essentially the same in all cases In uncomplicated cases patients were allowed up on the twenty-eighth day and dismissed on the forty-second day from the onset of the illness. Complications of the same type were treated similarly The only variable factor in the treatment was the administration or nonadministration of antitoxin or convalescent serum. Twenty-nine patients did not receive serum of any kind Eighty-four patients were treated with the concentrated antitoxin, of whom seventy received 10 cc. of antitoxin and fourteen received from 20 to 30 cc. of antitoxin.

Convalescent serum in doses of from 6.5 to 8 cc. was given in three cases. *The most striking result of the administration* of the antitoxin in the first few days of illness was the rapid clinical improvement as shown by the disappearance of the toxemic symptoms. Vomiting ceased, the throat became less painful, the cervical glands diminished in size, cyanosis disappeared, the rash faded, and moderate desquamation was followed by fine unobtrusive powdering. With the fading of the rash, usually in from six to twelve hours after the administration of serum, there followed a critical fall of temperature, from hyperpyrexia to a subfebrile level, accompanied by a general improvement in the pulse. The patient emerged from the acute stage of the disease to the security of convalescence. The incidence of complications was greater in mild cases which were not treated with antitoxin than in more severe cases treated with 10 cc. of antitoxin. While there is evidence that scarlet fever streptococcus antitoxin has some definite effect in reducing the occurrence of nonseptic complications, there is no evidence that scarlet fever streptococcus antitoxin (*a*) diminishes the occurrence of septic complications, (*b*) delays the onset either of septic or of nonseptic complications, or (*c*) shortens the duration of septic or nonseptic complications.

Medical Treatment of Cancer.—Todd and his associates have been using a combination of lead with selenium in the treatment of cancer. The preparation is available to all, being a 0.4 per cent solution of lead selenide, a nontoxic colloid. As much as 33 cc. has been given in one dose without adverse effects. The size of the initial dose depends on the nature of the neoplasm. The colloid is injected intravenously at weekly intervals. The size of the later injections depends on the amount of focal and general reaction. It is claimed that the treatment has a favorable action in the majority of the cases; it is estimated that in about one fifth of the patients there is *no appreciable result*, but in the remainder more or less improvement is found to follow. Radiation therapy concurrently with selenide is also employed. There have been results which give *promise of this combination being useful. In view of the known* fact that lead tends to be stored in the bones as a compound lead-calcium phosphate, he considered that the patients ought also to be treated with any substance likely to diminish this storage; otherwise any condition associated with acidosis would occasion a liberation of unknown amounts of ionic lead from the skeleton and cause lead poisoning. The obvious remedy was calcium chloride, which was given to all patients daily. In the hope of increasing the assimilation of calcium, patients are given the fat-soluble vitamins. Large doses of vitamin D appear to be really useful when the amount of oily solvent can be tolerated. A small daily dose of thyroid extract is also given, and finally, to combat the anemia usually present in advanced cancer and the anemia occasioned by prolonged injection of lead compounds, they give the patients liver extract. In conclusion, Todd advises that such cancers be treated as are likely to be influenced with radiation first, and as thoroughly as possible. After irradiation is over and the patient has had time to recover, treatment should be instituted by his method. In inoperable cancer as much as possible should be removed by surgical means and afterward one should attempt to make the remainder regress with selenide. Especially he advises giving the treatment after operations which are regarded as having been complete. Finally, he strongly advises that the whole of the method be used: (1) lead selenide to increase local and general defense mechanisms; (2) calcium chloride to increase ionized calcium by acidosis, to correct alkalosis, and to furnish a depot for calcium assimilation; (3) fat-soluble vitamins in large doses, especially vitamin D, to increase calcium absorption and to combat any infective element; (4) small doses of thyroid extract as a tonic and antiinfective agent; (5) liver extract to combat anemia.

Rheumatism in Childhood.—Sheldon states that unless it *can be shown that tonsillectomy* has a definite influence in the prevention of cardiac disease, there seems small justification for the operation merely on the ground that the child is a rheumatic subject. Of 600 consecutive cases of rheumatism at the rheumatic clinic at Great Ormond Street, tonsillectomy has been performed in no less than 540 (90 per cent). Of these patients, 393 were operated on before their admission to the clinic. In approximately one third of the cases of rheumatic pains, chorea and rheumatic fever commenced these symptoms of rheumatic infection after the tonsils had been removed. In addition, the pains continued after the operation in half of 105 children who *had rheumatic pains in the limbs before* the removal of their tonsils; and of 93 children who had chorea before removal of their tonsils the chorea relapsed after the operation in 27 per cent. *Analysis of 266 children with* rheumatic heart disease showed that in 46 cases (17 per cent) the tonsils had been removed before signs of cardiac disease were discovered. It seems more probable that the value of tonsillectomy in rheumatic children is in proportion to the degree of impairment of the general health attributable to the tonsils. In other words, the tonsils of rheumatic children should not be removed unless there is evidence that they are affecting the general health adversely. Such evidence as a history of repeated sore throat, chronic enlargement of the tonsillar glands in the neck, and the appearance of the tonsils must all be taken into consideration. The size of the tonsils alone is an unreliable guide, small scarred tonsils being often as injurious to the child's health as hypertrophied tonsils.

Triketohydrindenehydrate as Reagent for Albumin, Peptone and Amino-Acids. H. Gardner.—p. 525.

Lung Puncture in Acute Lobar Pneumonia.—In cases of acute lobar pneumonia without sputum, or with very little sputum, where for therapeutic reasons it is desirable to know the type of organism as soon as possible, Stewart advocates lung puncture. Lung puncture was performed in seventeen cases of acute lobar pneumonia. A pneumococcus was isolated from the "lung fluid" in thirteen out of seventeen cases.

Glandular Fever.—One case is cited by Bland in which inoculation of the blood into a rabbit was followed by a disease which is transmissible to other rabbits by the citrated blood. This disease is characterized by fever, anemia, leukopenia and monocytosis, enlargement of the lymph glands, spleen and liver, and the production of focal necroses in them. The relationship of this disease to human glandular fever is discussed. The name "experimental glandular fever" is *suggested for the disease in* rabbits.

Apparatus Designed to Diminish Incidence of Postoperative Thrombosis.—Braithwaite uses a simple form of gymnastic apparatus. There are three pulleys, one (double) at the head and one each (single) at foot and hand. The apparatus is fixed to the head rail of the bed and is used first on one side and then on the other. A light cord is threaded through the pulleys and there is a means of lengthening or shortening the length of the cord. The stirrup and handle are of soft, well padded canvas. It is used for all abdominal operations, beginning as a rule on the fourth day. Some patients will try it earlier and others cannot and will not use it until later; some will not use it at all. At the beginning the patients can exercise for only about two minutes, but the time soon arrives when they are able to work the apparatus for five minutes at each side. In some cases they enjoy the exercise and will ask for it and work it for longer periods. The idea underlying the exercises is to prevent stagnation of blood, especially in the pelvis and lower part of the abdomen. By pushing with the hand the leg is pulled well up to the abdomen and at the same time good exercise is given to the arm. People who have assiduously carried out these daily "jerks" are not only happier for it while in bed but when the time arrives to get up they are much better able to move about.

Purpura Simulating Acute Abdominal Conditions.—In one of Fraser's cases a diagnosis of intussusception was made. Free fluid was found in the peritoneal cavity, and the intestinal wall and mesentery were studded with petechial hemorrhages and ecchymosed patches. Careful examination later revealed many minute small hemorrhagic points which had escaped notice with artificial light. These pinpoint hemorrhages were more marked during the convalescent period. In the other the diagnosis was acute gangrenous appendicitis. At operation a large quantity of nonpurulent blood-stained fluid escaped. The last *two feet of the ileum were brilliant scarlet and showed numerous* small black areas of hemorrhage. The intestinal wall was markedly thickened with the blood contained in the tissues. The hemorrhage stopped more or less abruptly at the ileocecal valve, leaving the cecum almost normal. The appendix was normal in every respect except that it contained a rich supply of threadworms. The rest of the ileum was mottled, the mottling gradually decreasing toward the jejunum. There were several enlarged mesenteric glands, some soft and others calcified. An examination of the abdominal viscera through this limited incision failed to reveal any further pathologic change. For *three or four days after the operation the motions were mixed* with dark blood, and on the third day the urine was heavily tinged with blood. The postanesthetic vomit contained blood and the saline solution returned after operation was tinged. On about the tenth day she had a severe attack of epistaxis, and about the same time a marked purpuric rash appeared, involving both feet and the outer sides of the ankles. This was so severe that the feet were almost blue. There was also considerable swelling of the ankles.

*Zinc Content of Animal Bodies. G. Bertrand and Y. Beauzemont.—p. 247.
Critical Temperature of Serum. P. Lecomte du Nouy.—p. 251.

Bacillus Gangrenae-Cutis.—Nativelle describes *Bacillus gangrenae-cutis*, first studied by Milian, which occurs with great frequency in many primary and secondary disseminated cutaneous gangrenes, in genital gangrenes and in scabs from various sources and in ulcers of the leg. While not usually the sole cause of gangrene, this bacillus is an important secondary germ of infection and often causes simple lesions and ulcers to develop into gangrene. Intravenous injections of arsphenamine counteract the action of the bacillus and have a curative effect on the gangrene itself.

Zinc Content of Animal Bodies: Age Variations: Influence of Milk Diet.—Bertrand and Beauzemont proved through experiments on seventy-one white rats that the proportion of zinc in the bodies of animals decreases from the time of birth to weaning because of the deficiency of zinc in the milk diet. The zinc content then increases throughout the period of rapid growth and remains constant in adults. In old age it again shows an increase.

*Test for Presence of Gonococcal Antigen in Urine. N. M. Ovtchinnikov and E. M. Sémeniako.—p. 577.

Test for Gonococcal Antigen in Urine.—Ovtchinnikov and Séméniako discuss the value of the test for the presence of gonococcal antigen in urine as determined by the complement fixation reaction developed and used by Lissonsky in testing for tuberculous infection. Observation of several hundred cases shows that this reaction is a valuable auxiliary method of diagnosis, especially in determining the moment of disappearance of infection during the course of treatment. A + or a + + reaction obtained only once, however, does not necessarily mean that gonorrhea is present; the reaction is not constant, and two or three tests are necessary for infallible results.

Journal de Chirurgie, Paris

36: 1-160 (July) 1930

*Methods of Restoring a Thumb. R. Gueullette.—p. 1.

Methods of Restoring a Thumb.—Gueullette gives the following classification of standard methods of restoring a thumb: (1) methods that utilize remaining parts of the mutilated hand, either phalangization of the first metacarpal or making the index finger a thumb; (2) methods of digital transplantation, using either a big toe or a finger of the other hand, and (3) methods of reconstruction that include successive cutaneous and osseous grafting (Nicoladini-Pierce method), simultaneous cutaneous and osseous grafting (Neuhauser-Albee method), and simultaneous cutaneous and osseous grafting after *preliminary transplanting of the osseous tissue* ((Schepelmann-Cotte method). The deciding factor in choosing the method to use is the social and economic status of the patient and the way the thumb will be used. For the hand of a workman a solid, strong thumb is important with no particular need for flexibility at the end, especially if the metacarpal is left. The Nicoladini-Pierce method seems best suited for this purpose. However, if the thumb is not to be used for labor and esthetic considerations enter into the decision, the most satisfactory results will be obtained by the grafting of a big toe. This will give a more natural looking and flexible thumb than the Nicoladini-Pierce method, although it will not be as solid.

*Infantile Asthma, Pruriginous Dermatoses and Hepatic Insufficiency: Infantile Arthritism Syndrome. H. Jumon.—p. 1138.
Causes of Onset of Labor. J. Fontes.—p. 1140.

Infantile Asthma, Pruriginous Dermatoses and Hepatic Insufficiency: Infantile Arthritism Syndrome.—Jumon says that asthma, certain pruriginous dermatoses and hepatic disturbances in young children form a homogeneous *clinical* ensemble. Although they never appear simultaneously, two or three often appear successively or even alternately in the same child and have the same pathogenesis, consisting of an alteration of *nutrition, either hereditary or acquired*, which predisposes the organism to factors otherwise harmless. This causes an instability of the body fluids and of the neurosympathetic system which reacts specifically in asthma, dermatoses or hepatic disturbance. These reactions are benign and tend to disappear before the age of 8 or 10 years. General methods of treatment which improve the alimentary system, and attention to diet and climatic conditions, produce the best curative results. The syndrome of this entire group of reactions may be termed the "infantile arthritism syndrome." In general, the successive appearance of two or more of these diseases in the same child is indicative of the source of the condition.

*Ileus Reflex in Course of Renal and Ureteral Lithiasis. D. Denechau and R. Prieur.—p. 1153.
Colorimetric Quantitative Determination of Nitrogen in Blood Serum: micromethod. A. Cassuto.—p. 1155.

Ileus Reflex in Course of Renal and Ureteral Lithiasis.—Denechau and Prieur point out the importance of distinguishing the ileus reflex in the development of renal and ureteral lithiasis from similar disturbances due to appendicitis, peritonitis and other sources. The principal symptoms to be observed are the sudden, violent beginning of the condition with intense pain in the abdomen (usually on the right), vomiting, intestinal retention and dysuric disturbances, and distention of the abdomen. The urine usually contains albumin, crystals of uric and oxalic acid and erythrocytes. The condition is caused by the penetration of a calculus into the ureter, which irritates the perirenal ureteral plexus and by the mesenteric nerves causes a reno-intestinal reflex, sometimes with spasmodic contraction. Relief is felt when gas and feces are expelled from the intestine, together with the calculus itself. The entire evolution of the disturbance rarely exceeds ten or twelve days. The secret of treatment is abstinence from operation, since intervention is always useless and often causes fatal results and the disease is sure to terminate in normal evacuation of the intestine in a few days. Palliative treatments to relieve pain and to stimulate normal intestinal action are recommended.

Internal Version in Cases of Cephalic Presentation with Pelvis Contracted at Inlet. J. Vanverts.—p. 497.
*Death of One Twin in Course of Gemellary Pregnancy. E Aburel.—p. 510.

Death of One Twin in Course of Gemellary Pregnancy.—Aburel says that when some pathologic factor, as the presence of syphilitic or tuberculous infection, causes the death of one fetus, the reduced intensity and slow development of the infection often allows the other fetus to develop normally. The unequal resistance of the two twins is due to an accidental knot or loop in the cord or to malformation. When death takes place shortly before term, the diagnosis of gemellary pregnancy is obvious. When death occurs earlier, however, excessive nausea and vomiting, as well as the fact that the uterus is unusually large at first, seeming to indicate gemellary pregnancy, and then tends to resume normal developments, with diminution of the fetal movements, are important pathognomonic indications. After the rupture of the membranes the amniotic fluid is chocolate colored from the macerated dead fetus. Delivery is usually normal and a little before term. The living twin usually is born first. In case of cesarean section it is necessary to ascertain by touch which is the living twin (the dead fetus is softer). The results of confinement are usually good. The living twin rarely suffers from the infection that killed the other twin and is normal in development.

Revue Neurologique, Paris

2: 1-192 (July) 1930

Subacute Necrotic Myelitis: Anatomic and Clinical Considerations. L. van Bogaert, R. A. Ley and F. Brandes.—p. 1
*Cerebral Tumors as Cause of Epilepsy. E. Moniz.—p. 18.
Opportunity for Suboccipital Drainage in Certain Endocranial Injuries. F. Ody.—p. 28.

Cerebral Tumors as Cause of Epilepsy.—Moniz says that cases of epilepsy that do not yield to ordinary methods of treatment, especially if they are of long duration and show jacksonian characteristics, are often due to cerebral tumors. Four cases are cited. In such cases roentgen examination reveals the presence of calcified tumors. If roentgen examination gives no results, arterial encephalography may be practiced to determine the presence (or absence) of tumors that do not produce opacity to roentgen rays.

Policlinico, Rome

*Symptomatic and Spontaneous Meningeal Hemorrhages. V. Cavalletti.—p. 1129.
"Surgical Abdomen" Due to Impalement: Case. E. Capecchi.—p. 1133.
Introflexed Sutures G. Baggio.—p. 1135.

Symptomatic and Spontaneous Meningeal Hemorrhages.—Cavalletti reports five cases of meningeal hemorrhages and makes certain observations on their symptomatology and pathogenesis. The treatment can be only symptomatic. The prognosis is favorable. Lumbar puncture aids in establishing the diagnosis and is, at the same time, the preferable form of treatment.

37: 309-360 (July 15) 1930. Surgical Section

*Primary Tumors of Liver. M. Ascoli.—p. 309.
*Hypernephroid Tumors of Kidney. G. Cicala.—p. 331.

Primary Tumors of Liver.—Ascoli analyzes the clinical histories of sixteen patients admitted to the Clinica chirurgica of Rome with a diagnosis of primary tumor of the liver. Two cases involved hepatic gummas; four, sarcomas; six, epitheliomas; one, a lymphangio-endothelioma; one, a cavernoma, and in two cases the diagnosis was only clinical. The malignant tumors have a rapid course, characterized by fever, pains, marked enlargement of the liver and ascites. The epitheliomas (chiefly hepatomas) occur in advanced age, while the sarcomas develop nearly always before the age of 40. In the cases of malignant tumors, one found in the history of the patients chronic inflammatory and degenerative lesions of the liver, sometimes also echinococcus cysts. The author discusses also the special diagnosis of gummas and hepatic abscesses.

Hypernephroid Tumors of Kidney.—Cicala points out that large benign tumors of the kidney present the greatest diagnostic difficulties and in most cases are diagnosed only at the operating table. In any case in which the diagnosis appears for various reasons doubtful, recourse should be had to exploratory laparotomy, the patient being prepared and everything being made ready for whatever operative act proves to be necessary. It should always be kept in mind that hypernephroid tumors are of long duration and occur almost always in adults, whereas sarcomas are more frequent in young persons, and mixed tumors more frequent in children. The prognosis in hypernephromas is exceedingly grave. Nephrectomy gives rarely good remote results. Recurrences are not infrequent. Only early interventions furnish hope of a radical recovery: yet early treatment is only rarely applicable. Patients often refuse to submit to an operation because of fear and because their symptoms undergo a temporary attenuation and they hope for a recovery without operation. Sometimes their medical advisers confine themselves to prescribing useless direct symptomatic remedies to combat the most alarming symptom—hematuria, which, as is well known, by reason of its periodic nature, reappears at long intervals, during which the patient enjoys perfect well being. All this causes a grave postponement of surgical intervention and makes the prognosis still more unfavorable. If a hypernephroma is diagnosed, nephrectomy should be done soon, for a good outcome, and especially the remote results, depend on an early operation. The contraindications result solely from the inevitable complications of cases tardily diagnosed (massive adhesions; paravertebral, axillary, inguinal or bone metastases). Cachectic or anemic appearance, varicocele or the large volume of the tumor does not, however, constitute a contraindication. The author prefers the extraperitoneal method of nephrectomy. He advises against routine removal of the suprarenals in all cases, as advocated by Grégoire—he recommends removal only when they are invaded by the tumor. The chief causes of death after the intervention are shock, hemorrhage, pulmonary embolism and reflex anuria. Recurrences develop (if at all) usually during the first year after the operation—either in the crater itself or in adjacent tissues. There may be metastases in distant organs, especially in cases coming late to operation.

Diaphragmatic Hernia. A. D'Istria.—p. 1037.
Algias and Their Treatment. F. Negro.—p. 1046.

Uricacidemia in Diabetes Mellitus.—De Candia states that hyperuricacidemia in diabetes mellitus signifies a disturbance of purine metabolism, although some authors, when it is not accompanied by true gouty symptoms, regard it as sometimes a simple functional and not always a pathologic alteration of the mechanism of the production and elimination of uric acid. Likewise, the low values of the uric acid in the blood circulation observed in some of his patients with grave diabetes must be interpreted as an alteration of purine metabolism, caused probably by a functional paralysis of the organ cells and by the retardation of the intra-organ oxidative processes, especially the liver. His results agree with those of Giorgi regarding the diminished elimination of uric acid in the urine in grave diabetes.

46: 1069-1108 (July 7) 1930

*Polypeptidorrhachia. N. Fiessinger.—p. 1071.
Organic and Functional Forms of Spasms and Tics. G. Colucci.—p. 1073.
Autochthonous Leprosy and Leprosy Contagion. A. de Amicis.—p. 1081.

Polypeptidorrhachia.—From his research, Fiessinger concludes, in harmony with Léon Michaux and Maurice Herbain, that polypeptides may be found in the cerebrospinal fluid. These large molecules are of local origin or are from the blood. The passage of fluid between the blood and the spinal fluid does not occur in accordance with any constant laws of diffusion. Polypeptidorrhachia may accompany cerebral symptoms, bulbar symptoms or meningeal symptoms. These toxic syndromes are more accentuated, the greater the increase in polypeptides with respect to the total nonprotein nitrogen. The syndromes affect hepatic and renal insufficiency, which directly or indirectly produce the insufficiency of cleavage of the polypeptides. The influence of polypeptides on meningitis of toxic origin may henceforth be admitted. The meningeal reaction should not be considered the absolute and constant result of the polypeptidorrhachia, but in certain conditions it appears to the author as the dominant disturbance and the expression of the preponderant intoxication. The author regards his brief considerations on polypeptidorrhachia merely as a preliminary study.

*Toxicity of Viosterol. R. Garelly.—p. 321
Treatment of Rickets with Viosterol: Roentgen Changes. J. L. Morales.—p. 336.
Climatotherapy in Bronchopulmonary Processes in Children. C. Sainz de los Terreros.—p. 372.

Toxicity of Viosterol Used in Rickets in Infants.—Garelly has obtained good results with the administration of viosterol in the treatment of rickets. The degree of toxicity of viosterol, however, is not yet well determined and hence the advisibility of great care in the dose and administration of the drug. In cases in which it is necessary to administer the drug for a long time, the calcium and phosphate contents of the blood should be frequently determined as an index for the continuance or the stopping of the treatment. The author has never observed toxic phenomena caused by the administration of the drug. He has observed lack of appetite and dyspeptic disturbances as a result of the treatment. As soon as the disturbances appeared, the dose of the drug was temporarily diminished and then slowly increased, without the reappearance of the deleterious effects. The method that has given the author the best results is the following: The treatment is started with a dose smaller than that which is generally advised, and slowly increased (in accordance with the general condition of the infant and with the particular condition of his intestine), until reaching the proper dose (either prophylactic or curative dose).

Carbuncle in Diabetic Persons.—Rodríquez Villegas says that carbuncles in diabetic persons should be removed early. Excision should include not only the necrotic area but also the area of subcutaneous cellulitis. Carbuncles in diabetic persons should be divided into two large groups thus: (1) benign or small lesions, similar to a union of furuncles, in which pain and edema are not intense and which as a rule develop in patients with benign diabetes, and (2) carbuncles of rapid development with intense pain and marked edema, which present a wide area of central necrosis and cause serious general disturbances, and which as a rule develop in patients with grave diabetes, who are generally obese and more than 50 years of age. In patients of the first group, treatment including cauterization with the actual cautery, passive hyperemia, phenolated fomentations, vaccinotherapy and roentgen rays may be sufficient. At the same time the progress of the diabetes should be determined frequently. If the patient does not improve under the treatment, excision should be resorted to. In grave cases of the second group, immediate and wide resection of the pathologic area, including the limits of the pyogenic infiltration of the cellular tissues, should be made. The author reports two cases: one of benign diabetes and acidosis due to the carbuncle and one of stationary diabetes reactivated by the development of the carbuncle. In both cases after an insufficient resection of the affected area a diffuse cellulitis dominated the clinical picture and necessitated a second intervention. Recovery ensued in both cases.

Exsiccated Alum for Dressings for Fractures and Diseases of Joints.—Benatuil prepared a mixture of 1,000 Gm. of exsiccated alum and 500 cc. of water to be used instead of plaster of paris, in making permanent dressing for fractures, dislocations and diseases of the joints. The substance transmits roentgen rays and solidifies twenty minutes after its application. After the dressing has been applied and before solidification of the mixture takes place, a roentgenogram may be made to determine whether the bones are in the proper position: if they are not, the dressing (which is still wet) may be removed and another attempt at reduction may be made.

Psychiatric Legislation for Care of Persons with Psychoses. J. M. Sacristan, G. R. Lafora and J. Escalas Real.—p. 32.

Specificity of Streptococcus in Scarlet Fever, Erysipelas and Puerperal Fever.—Salazar says that the toxins of erysipelas and of puerperal fever cause a local skin reaction similar to that caused by the Dick test in scarlet fever. With the toxins of erysipelas or of puerperal fever, antitoxic serums, highly specific against the given infection, may be prepared. These serums cause the agglutination of the respective streptococcus. The discovery of the specificity of the toxins of scarlet fever, of erysipelas and of puerperal fever has resulted in a definite advance in the diagnosis and therapy of these serious infections. By means of dermic reactions, susceptibility to the infections may be discovered and by the proper use of the suitable specific serums the diagnosis, the prophylaxis and the cure of these streptococcal infections may be obtained. The efficacy of specific serums is surprising and their superiority over polyvalent serums has been demonstrated. Each one of the three infections should be treated with the specific corresponding serum to obtain the exclusive action of the serum against its homologous toxin.

*Treatment of Anemia in Children. H. Rau.- p. 1217.

Treatment of Meningitis During Epidemic in Shanghai.—During the meningitis epidemic in Shanghai, the intraspinal injection of polyvalent antimeningococcus serum brought favorable therapeutic results. In severe cases, lumbar puncture was at first done every day. Immediately after the puncture the serum was injected in a quantity somewhat smaller than the quantity of cerebrospinal fluid withdrawn. The serum injection never exceeded 25 cc. During the beginning stage this method of treatment was repeated every day. Later it was repeated after intervals of from two to three days, according to the severity of the case. In some patients the total amount of serum injected intraspinally reached 220 cc. On the days on which the spinal injections were omitted, the serum was injected intramuscularly. Virnich asserts that the administration of large quantities of serum did not lead to complications. He thinks that the low mortality rate was the result of the serum therapy. When the supplies of serum ran short, intravenous injections of methenamine were administered but this form of treatment was less effective than the serum therapy.

Treatment of Anemia in Children.—Rau states that among children the secondary anemias are more frequent than the primary forms. According to their etiology he classifies the forms of secondary anemia into alimentary, infectious, postinfectious, constitutional and helminthic. In discussing the therapy he stresses the value of a correct diet, administration of iron preparations, liver diet and blood transfusions. In many instances diet alone will counteract the anemia. Inorganic iron preparations are likewise effective in many instances. When liver therapy becomes necessary the liver should be given in the form of extracts, because in this form it is most easily taken by children. Blood transfusion is the most effective method, but even this is not helpful in all instances. In most cases it is difficult to decide which treatment will bring the best results. Accordingly, the author recommends that liver extracts and iron preparations be given simultaneously and in severe cases blood transfusion should also be employed. This combination therapy gives better results than if each method is employed alone.

*Treatment of Suppurative Meningitis. W. Mann.—p. 1306.
Serious Complications Caused by Intra-Uterine Pessaries. K. Tietze. —p. 1307.

Treatment of Suppurative Meningitis.—Mann points out that the prognosis in suppurative meningitis is still unfavorable. Numerous therapeutic methods have been employed; namely, lumbar puncture, administration of serum, protein therapy, serotherapy, and treatment with a solution of methenamine. The latter method, however, may cause complications in the central nervous system. Another treatment that has been employed successfully by several authors is the irrigation of the subarachnoid space following lumbar puncture, by means of physiologic solution of sodium chloride or Ringer's solution. Irrigations after suboccipital puncture have also been recommended. In some cases irrigations through the lumbar puncture might prove sufficient. However, in severe cases irrigations through the suboccipital puncture are necessary. The latter procedure permits a closer approach to the focus of suppuration, which is usually at the base of the brain, and it also prevents or counteracts adhesions. But because suboccipital puncture is more dangerous than lumbar puncture, it should be employed only if absolutely necessary. In most cases the irrigation has to be repeated every day or every second day. The author reports the results of irrigation treatment in three severe cases of suppurative meningitis. In all instances the cerebrospinal fluid became clear. In two instances the irrigation by means of lumbar puncture did not prove sufficient, and adhesions developed on the foramen magnum. In one of the cases the adhesions were overcome by irrigations through a suboccipital puncture. In the other case, in which suboccipital puncture had not been resorted to, the adhesion led to a fatal outcome. It was also found that the cerebrospinal fluid that was obtained by suboccipital puncture showed greater pathologic changes than the fluid that was obtained by lumbar puncture. Specimens of cerebrospinal fluid that had been obtained during the period of recovery always showed a spider-web coagulation from two to four hours after extraction. This proves that the sign is not pathognomonic for tuberculous meningitis.

Treatment of Anemia in Children by Means of Bone Marrow Preparation.—On the basis of his experiences with red marrow from the ribs, which proved effective in experimental secondary anemia (*Deutsche med. Wchnschr.* **56:**521 [March 28] 1930; abstr. The Journal, June 14, 1930, p. 1962), Borchardt employed a bone marrow preparation, containing not only the hematopoietic factor but also the entire calcium of the bone, in the treatment of thirty-five anemic children, who were inmates of an orphan home. The hemoglobin content and the number of erythrocytes was low and some of the children were underdeveloped, had swellings of the cervical lymph nodes, had blepharitis and were pale. Their ages varied between 3 and 14 years. These anemic children were given a teaspoonful of the bone marrow preparation three times daily. The treatment was continued from December until March. The hemoglobin content, the number of erythrocytes and the body weight were determined weekly and a considerable improvement was noted. In several other inmates of the orphan home, who likewise were anemic and in poor health but who had not received the bone marrow preparation, improvement was hardly noticeable.

Attempt at Roentgen Treatment in Chronic Encephalitis.—Because irradiation with roentgen rays has been effective in many inflammatory processes, Trautmann and Pansdorf employed it in six cases of chronic encephalitis. The rays were applied on three fields, two temporal and one occipital. The distance was 40 cm. and the quantity was 10 per cent of a unit skin dose. A 0.5 mm. copper filter was used. The intervals between the irradiations were usually four days. The authors give the case histories of the six patients who were treated in this manner. In none of the cases was improvement noted.

Accordingly the authors conclude that in cases of chronic encephalitis roentgen treatment is not effective. This indicates that inflammatory processes in the brain differ from inflammations in other organs. The authors assume that the efficacy of roentgen rays in inflammations outside the central nervous system are due to their mobilizing effect on the function of the supporting tissue; their inefficacy in inflammations of the brain is due to the fact that the glia cells do not react to the roentgen rays like other supporting tissues.

Complications Following Treatment of Hernia with Alcohol Injections.—Goldhahn describes three cases of hernia in which alcohol injections caused serious complications, such as sepsis, fecal fistulas and injury of the vas deferens. Other authors observed ileus and gangrene of the testes following alcohol injections. Occasionally it might be possible to close a small hernial opening by the injection treatment. However, the results are doubtful and, in view of the serious complications that might result, alcohol injections should no longer be employed for treatment of hernia. Because some physicians still employ this "nonsurgical" method, the author considers it necessary that the medical press should warn against it.

Relation Between Diseases of Blood and Diseases of Mucous Membrane of Mouth.—Lindemann directs attention to the correlation between diseases of the blood and diseases of the mucous membrane of the mouth. He mentions the soreness of the tongue in pernicious anemia. Then he reports the clinical histories of three patients who showed such symptoms as sore throat, soreness of the tongue and soreness of the gums. Careful examination of the blood revealed abnormal conditions. In the conclusion the author stresses that a blood count is advisable whenever inflammations in the pharyngeal region show some unusual aspects.

Modification of Basal Metabolism by Thymus and Spleen Extracts.—In the first part of the article, Schneider and Nitschke review the observations of various authors on splenectomized and on thymectomized animals. They further report that Nitschke succeeded in extracting from the thymus two substances, of which the one effected a decrease in the calcium content of the blood of rabbits and the other reduced the inorganic phosphorus content. The substances were detected also in the spleen and in the lymph nodes; that is, in the entire lymphopoietic system. In other organs, however, they could not be found. In order to determine whether extracts from the spleen and thymus influence the basal metabolism, the authors made tests on guinea-pigs. Experiments with the substance that reduces the calcium content of the blood proved that it has no influence on the basal metabolism. However, the extract that reduces the phosphorus content, and which is extracted from the spleen and thymus by means of acetic acid-alcohol and ether, decreased the basal metabolism not only in normal animals but also in those in which the basal metabolism had been increased by means of thyroxine. The average reduction was 22.9 per cent. The thymus and spleen extracts used for the experiments contained neither proteins nor fats. The injections were given subcutaneously. Control experiments were made with liver and muscle extracts, hypertonic solutions of sodium chloride and other extracts. However, an influence on the basal metabolism was not observed.

Pulmonary Foci in Lymphogranulomatosis.—Saupe maintains that the pulmonary foci in lymphogranulomatosis are not as rare as is assumed by many authors. As proof he cites his observations on ten patients and reports by other authors. However, he admits, and by that confirms the statements of other authorities, that pulmonary foci of lymphogranulomatosis are only rarely diagnosed roentgenologically because other pathologic processes show similar roentgenograms. Cancer of the hilus of the lung with large mediastinal metastases gives almost the same roentgenogram as pulmonary lymphogranulomatosis. However, the bilateral broadening of the mediastinum speaks more for lymphogranulomatosis, the unilateral broadening more for cancer of the hilus. Lymphogranulomatosis of the lung is often accompanied by pleuritic exudates or transudates and by bronchopneumonic processes, and these conditions mask the lymphogranulomatosis and it is not recognized in the roentgenogram. The author also discusses the relation between pulmonary tuberculosis and lymphogranulomatosis. In one case reported by him there existed a disseminated pulmonary tuberculosis and the mediastinal lymph nodes were affected with lymphogranulomatosis. However, there were no granulomas in the lungs. Regarding the therapy of lymphogranulomatosis, the author states that roentgen irradiation often brings improvement. However, it is usually only temporary. Postmortem examinations proved the frequency of bone involvement in lymphogranulomatosis.

Irradiation of Body Cavities by Means of Ultraviolet Rays Produced Therein.—Westmann points out that attempts have been made to irradiate the body cavities with ultraviolet rays. In order to introduce the rays, quartz mirrors were used; but, as this method proved unsuccessful, an instrument was perfected that would produce the ultraviolet rays within the body cavity. The apparatus consists of a bipolar spark-gap that is enclosed in a quartz tube. Quartz is likewise used for insulation of the conducting wires. The author gives illustrations and a detailed description of the instrument. The efficacy of the instrument was tested on animals. In the conclusion the author mentions conditions in which the instrument might prove of therapeutic value.

Pathogenesis and Therapy of Tuberculous Hemoptysis.—Edel discusses two forms of hemoptysis. To the first group belong the minor hemorrhages that usually continue for longer times and in which the blood does not escape from ruptured vessels but rather by diapedesis. To the second group belong the fulminant hemoptyses, which result from the rupture of aneurysmal pulmonary vessels. The first group may be due to various factors, to an increased permeability of the capillary walls, to toxic injuries, to sympathetic or incretory disorders, to inflammatory hyperemia and to meteorological conditions. In the diapedesis hemorrhages there generally exist serious pneumonic or productive, nonshrinking processes. The profuse fulminant hemorrhages usually occur when large parts of the lung contract as the result of chronic processes. The vessels become constricted by compact connective tissue indurations. Emphysematous conditions in the other parts of the lung and cardiac decompensation promote the stasis in the stenosed vessels. Then varicosis develops and the thin, dilated wall of the vessel ruptures from the slightest irritation, such as an attack of coughing. Between these two main forms stand the hemorrhages from the scars at the apex of the lung and the initial hemoptysis in early infiltrates. Both of these are arrosion hemorrhages and are of minor intensity. The fact that the same pathologic conditions in some persons lead to hemoptysis and in others do not, shows that certain constitutional factors must be involved, as diathesis, toxic injury of the walls of the vessels, and coagulation anomalies. In discussing the therapy of hemoptysis the author states that the first aim should be to increase the coagulability of the blood. He points out that the mechanism of coagulation is as yet not entirely understood. Some consider it a chemicosynthetic process and others a colloidochemical process. The pharmacodynamic mechanism of most hemostatics is not clear and, according to the author's experiences, most of them fail in severe hemorrhages because they supply only one factor involved in the process of coagulation. The author further mentions several hemostatics and shows their shortcomings. Then he discusses the methods that he has found helpful. Minor hemorrhages, even if they continue for some time, do not endanger the life of the patient and do not necessitate therapeutic intervention. The patient should be kept quiet, coughing should be counteracted, and care should be taken that the patient has regular bowel movements. A thorough clinical examination should not be made until two days after the bleeding has ceased. The author asserts that the use of hemostatics never caused an earlier cessation of the hemorrhage than in cases in which a hemostatic was not used. On the contrary, he noted an increase in the hemorrhage following intravenous injection of calcium preparations. Profuse hemoptysis, which endangers the life of the patient, requires prompt therapeutic action. Most hemostatics, with the exception of protein injections, were failures in these conditions. Collapse of the bleeding lung by means of pneumothorax is advisable only if it is known which side of the lung is affected. As the best method the author recommends blood transfusion. He employed it successfully in eighteen cases of tuberculous hemoptysis. The usual amount transfused was from 80 to 100 cc.

Treatment in Collapse Caused by Arsphenamine Injection.—Wirz states that the collapse conditions that sometimes develop after injection of arsphenamine occasionally have a fatal outcome. He describes the clinical aspects of arsphenamine collapse and then discusses its pathogenesis. Postmortem examination of a patient who had died in an arsphenamine collapse proved that the heart and the peripheral vessels were almost empty. The arteries are strongly contracted during the collapse and the administration of circulatory stimulants is frequently ineffective. Therefore the author recommends that the vascular tonus be improved by the application of heat. He gives two case reports in which he employed this method. The patient was placed immediately in a hot bath. Already after half a minute the sallow, greenish-blue skin became reddish, the pulsation was again perceptible and consciousness returned. The patient remained in the bath for five minutes. Then he was wrapped in blankets and camphor was administered. After several hours he had recovered sufficiently so that he was permitted to go home. Similar favorable results with the hot bath were obtained in a woman who had suffered an arsphenamine collapse. In the conclusion the author points out that the hot bath might also prove helpful in other forms of collapse.

Increase in Cancer in Bavaria.—Mertens discusses various shortcomings in medical statistics and especially in statistics regarding cancer. Official reports indicate that cancer is on the increase in Bavaria. The author points out that many authorities believe that this increase is only apparent and not real. Two factors are usually cited as being responsible for the apparent increase, namely, the fact that modern diagnostic methods detect a larger number of cancer cases and also that a larger number of persons reach the higher age groups, and cancer is mainly a disease of the aged. However, careful analysis of the statistics convinced the author that these statements are not entirely correct and that there is a real increase in the number of fatalities from cancer.

Influence of Muscle Extract on Heart.—Bagdassarjanz and Turkeltaub direct attention to Schwarzmann's investigations on the efficacy of muscle extract in the treatment of angina pectoris. They name several other authors who successfully employed the extract (from striated muscles of calves) in various cardiac disorders. The authors themselves gave subcutaneous injections of the muscle extract in fifty-four cases, and they tested the efficacy of the treatment by means of the electrocardiograph. They give the case histories of nine patients. Their observations are summed up as follows: 1. Under the influence of the extract the frequency as well as the intensity of the pains become reduced. 2. In patients with hypertension the blood pressure decreases, in those with hypotension it increases, and in normal persons the pressure either decreases slightly or remains unchanged. 3. Following the injection the cardiac rhythm becomes slower. 4. This retardation can be demonstrated with the electrocardiograph in the tenth minute after injection. 5. The retardation of the rhythm lasts longest in patients with tachycardia. In patients with bradycardia the rhythm becomes somewhat accelerated from forty to sixty minutes later.

Adenoma of Mammary Gland During Pregnancy.—A woman, aged 18, in the fourth month of her first pregnancy, had always been healthy. Three weeks previously, however, she had noticed a small nodule in her right breast, which grew rapidly. Examination revealed a firm nodule in the upper external quadrant of the right breast. It was diagnosed as a fibro-adenoma. The tumor was extirpated. It showed no connection with the parenchyma of the gland. Microscopic examination revealed that it was an encapsulated epithelial formation, in which connective tissue occurred only in the form of small septums that divided the lobes. The lobes showed the structure of a mammary gland. In reviewing the literature, Kreibig found reports of two similar cases. Both of the patients were young, aged 20 and 21, respectively, and in both the growth became noticeable during pregnancy. The author comes to the conclusion that these adenomas have a certain relation to pregnancy and that they might be considered as adenomas that hypertrophied as a result of pregnancy. These adenomas are the tubular form. They are noteworthy not only because they are comparatively rare but also because they show to what extent an abnormal growth may adapt itself to the surrounding tissues, and they also prove that a tumor of the breast with rapid development during pregnancy is not necessarily a malignant growth.

Resection of Duodenal Ulcer.—In the first part of the article, Mandl mentions the various surgical methods that are employed for the treatment of peptic ulcers. In the second part he gives a statistical report on cases of duodenal ulcer. Cases in which gastro-enterostomy was done are not discussed, but the author reports eighty-one cases in which resection was performed. In thirty instances Finsterer's modification of the Billroth II operation was employed, and in fifty-one cases his resection for exclusion was done. In the latter method, unilateral exclusion of the pylorus is combined with an extensive resection of the stomach. The aim of the method is sure exclusion of the ulcer and a healing of it, and the object of the extensive resection of the stomach is to do away with hyperacidity and thus prevent an ulcer in the jejunum. Of the thirty patients in whom resection was done twenty were entirely free from pain, six were improved, two died and two were not improved. Of the fifty-one patients in whom resection for exclusion was done thirty-four were cured, eight showed improvement, two died, and seven were not improved. The statistical report is followed by a critical evaluation of surgical methods that are employed in the treatment of peptic ulcers. In the conclusion the author states that, if definite signs of an ulcer are absent, surgical intervention is not indicated. Whenever an ulcer exists, resection is probably the best method because, if the ulcer is removed, hemorrhage and perforation are prevented. However, resection cannot always prevent a jejunal ulcer. Considering the physiology and the chemism of the stomach, it seems advisable that in all resections of an ulcer, the antrum and the pylorus should also be resected. Although the resection for exclusion improves the chances for a healing of the ulcer, it does not guarantee the cure. The operation does not prevent later hemorrhages or a jejunal ulcer. It is inferior to resection and whether it is better than gastro-enterostomy cannot be decided as yet.

Surgical Diathermy in Treatment of Wounds.—Spitzmüller describes a method for the treatment of primary accidental wounds. It is a disinfection by means of surgical diathermy. The author reports his observations in 100 cases. He asserts that infection was prevented in all instances. He therefore recommends that disinfection by means of surgical diathermy be tried in other cases, and he thinks that it will prove to be superior to disinfection by excision with the surgical knife.

New Instrument for Endovesical Electrocoagulation. E. Bors.—p. 1988.

Continuous Evacuation of Stomach in Treatment of Postoperative Ileus.—Jancke feels that this procedure has not received the recognition it deserves. Passing the tube through the nares has distinct advantages over swallowing the tube. A favorable effect is noted within a few hours. If not, the tube may be left in place for twelve hours at a time, when it should be removed to obviate the occurrence of ulcers in the esophagus. If after forty-eight or sixty hours the ileus has not disappeared, enterostomy is indicated. He has never performed a gastrostomy. The tube meets every expectation that a gastrostomy would and is much better for the patient. Five cases are cited.

Treatment of Actinomycosis with Lymph Node Preparations.—Having noted that actinomycosis develops only in tissues free from lymph nodes, Trauner concluded that it probably would be advantageous to add to the usual treatment of this condition an injection of lymph node juice, or an extract, alcoholic or aqueous. He used mostly the cervical lymph nodes of cattle but also took some from horses. The amount was 1 or 2 Gm. of gland substance in 1 cc. of fluid. This was embodied in the dressings, instilled into the abscesses or fistulous tracts and finally was injected into the cicatricial tissue. The effect of this treatment was apparent after a few days.

Operation for Ectopic Bladder.—Roloff reports two cases in which he performed Maydl's operation for this condition. One patient was a woman who had been operated on eighteen years previously. She married recently and became pregnant. Because of an increasing tetany of the uterus which could not be controlled medically, a cesarean section was performed. Both mother and baby died. The cause of death was not determined. The point is that the patient had been well for eighteen years and that she went through the pregnancy without any disturbance that could be charged to the operation. The second patient was a boy, aged 15, operated on five years ago. He was in splendid condition at the time of reporting.

Plastic Operation for Repair of Diastasis of the Abdominal Rectus.—Abrashanow uses strips of fascia lata which are passed completely around the muscles, but only in cases in which the separation is greater than 10 cm. The anterior sheath of the muscle is then closed in the usual manner. This preserves the state of the muscle both anatomically and functionally.

Menstrual Cycle of Human Vagina. K. Dierks.—p. 1882.

Interruption of Pregnancy in Congenital Hereditary Cataract or in Tumor of Brain.—Fleischmann reports the case of a woman with congenital cataract of both eyes who was in the fifth month of pregnancy. The anamnesis revealed that cataract and amblyopia were hereditary in this family. In four generations, fifteen of thirty-four members had had these disturbances. From the eugenic point of view it seemed advisable, therefore, to perform an abortion. However, because an abortion in the fifth month is not without danger for the mother, it was decided that this time the pregnancy should be allowed to go to term. The woman gave birth to a healthy girl but five months after parturition she consented to be sterilized. The author regrets that in the present day laws regarding abortion eugenics are not taken into consideration. In the second part of the article he discusses the case of a gravida with a tumor of the brain. The pregnancy was not interrupted and the woman gave birth to a macerated male fetus. The mother died several weeks later. The author states that the concurrence of tumor of the brain and pregnancy is rare but he thinks that, if such a case occurs, a committee of medical authorities should decide whether an abortion is advisable.

Rupture of Aorta During Puerperium.—Böhm reports a case in which rupture of the aorta caused the death of a woman, aged 31, on the sixth day after parturition. Examination before the beginning of labor revealed that the heart was enlarged in both directions, especially on the left side. An abnormal systolic sound could be heard and the second aortic sound was accentuated. The birth was spontaneous. On account of the cardiac disorder, the heart action of the mother was carefully observed, but complications did not develop. The postpartum period was normal up to the fifth day, when the patient felt a sudden sensation of pressure behind the sternum. She died eighteen hours later. At first it was thought that death was caused by thrombosis, by embolism or by heart failure, but the necropsy revealed a rupture of the aorta. The author further discusses the various conditions that may lead to rupture of the aorta. He mentions congenital weakness of the aorta, syphilis, pregnancy and the puerperium. One of these factors or several combined and an abnormally high blood pressure led to the rupture of the aorta. The case shows that, if an insufficiency of the aorta is detected during the early stage of pregnancy, interruption of pregnancy might be advisable.

Contraindicated Ecbolics.—Puppel is of the opinion that the potent ecbolics are employed more often than is advisable and that they may lead to rupture of the uterus. He discusses several ecbolics and states when they should be used and when they are not advisable. Ecbolics are indicated in cases of abortion especially when the patient is feverish. During parturition, ecbolics are indicated only during the period of expulsion when the head is on the floor of the pelvis and is nearly visible. At this point the gravida often loses her strength. During the placental stage the intravenous administration of an ecbolic is advisable if hemorrhages set in and when the expulsion of the placenta is retarded. In a cesarean operation an ecbolic should be administered after the extraction of the child. However, in cases of primary weakness of the labor pains during the period of dilatation, ecbolics are contraindicated. Their use is also not advisable when during the period of expulsion the labor pains become weak as a result of exhaustion. Ecbolics are likewise contraindicated when the uterine contractions are strong enough but extremely painful, for in these instances there exists a danger of rupture of the uterus. In all instances in which the physician thinks an injection necessary, he should observe the patient for some time before he gives it. Midwives should not be permitted to give injections.

Care of Umbilical Stump.—Karp points out that the opinions of authorities differ as to whether it is more advantageous to sever the umbilical cord close to the skin margin of the umbilicus or farther away. Some advise a close division to make the asepsis less difficult, and this method is practiced in the majority of obstetric clinics. However, the disadvantage of the procedure lies in the fact that, if an infection develops, the way to the peritoneum is short and the danger of peritonitis is greater. The difficulties of a possible secondary hemorrhage in case of a close division should likewise not be underestimated. *To eliminate such difficulties the author adopted Scherbak's* method. The umbilical cord is severed from 12 to 15 cm. away from the umbilicus. Following ligation of the stump about 2 cm. from the margin of the umbilicus the bandage is applied. Differing from Scherbak, the author applies to the umbilical stump a gauze compress, saturated with alcohol. He advises against ointment bandages. He has employed this method since 1925. Among 2,000 confinements, a subsequent cauterization of the umbilical stump was necessary in only six instances. In these cases a Paquelin cautery was employed.

Experimental Researches on Etiology of Scarlet Fever, Dairen, 1929. H. D. Boer.—p. 111.

Anemia with Icterus: Case in Child.—Peljak describes the peculiar case of a girl, aged 10. Up to the age of 5½, the patient was a healthy child and had a good color. She suddenly became ill with pain in the abdomen, squeamishness and high fever. She awoke the next morning with a yellow color of the skin, over her whole body. The urine was dark brown, and the stool had an unusual appearance. After ten days, the yellow tint had disappeared and the child was well again. At the same time a brother, one and one-half years older, presented precisely the same *symptoms*. He also had been well up to this time and had always had a good color. The mother doesn't remember whether either child was yellow the first few days after birth. The three following years after this morbid process, the girl again became yellow in the same month (August) as before. At the same time, she was languid and had no appetite. When 6½ years of age the child had a mild exanthematic disorder, at which time she was yellow, and had sore throat. At 10 she was still more or less yellow and was languid and apathetic; also the brother became paler and had several attacks of yellowishness of the skin, but, except for the slight icterus (especially of the sclerae), he was not ill. No other member of the family had ever had icterus. In the feces of the girl, a few oxyurids were found. Oil of chenopodium was administered and a large quantity of oxyurids were eliminated, as a result. The erythrocyte count was 3,030,000, and the leukocyte count was 10,000. Conspicuous in the blood was the large number of small chromocytes, which were dark red. These contrasted strangely with the usually larger and pale type. Hemolysis began in a 0.62 per cent solution of sodium chloride. In a 0.4 per cent solution about half of the erythrocytes were dissolved, and in a 0.3 per cent solution nearly all were dissolved. Normally dissolution begins with from 0.38 to 0.42 per cent solution, and total dissolution occurs with a 0.3 per cent solution. The child was given a diet with large quantities of milk, poor in fats but rich in raw fruit and green vegetables. To improve her appetite, she was given, three times a week, an ounce of liver, also syrup of ferrous iodide. Several days' rest in bed, at the start, was prescribed. She was left in the care of the family physician. When the author saw her five weeks later, the fatigued appearance had disappeared. She looked much better and had slightly pink cheeks, was not so yellow and had a good appetite. The blood picture, however, did not show much improvement. Roentgen irradiation of the spleen was tried for four weeks (five 2/10 erythema doses). The spleen was possibly slightly reduced in size but the irradiation had no influence on the blood picture. The author thinks that, in spite of the improved condition of the child, only extirpation of the spleen will effect a permanent improvement in this case of hemolytic icterus. He is not prepared to say whether it is a question of congenital familial hemolytic icterus or whether the same noxa produced similar conditions in brother and sister, at the same time.

Diet Treatment in Tuberculosis. F. G. Dahll.—p. 854.
*Subphrenic Abscesses. B. Dahl.—p. 860.
Biologic Significance and Therapeutic Application of Magnesium. B. Dahl.—p. 877.

Recurrent Vomiting and Acetonemia in Children.—Salomonsen says that this disturbance is due to an exhaustion of the nervous system or certain parts of it, and treatment should be along psychic lines.

Unusual Complication in Regular Enucleation.—In Gjessing's case of advanced glaucoma, with excellent results after antiglaucomatous iridencleises with meridional iridotomy *according to Holth in the better, right eye six years earlier,* enucleation of the left eye under local anesthesia according to Seidel was followed by temporary complete amaurosis and continued defect in the field of vision. As the anterior chamber was half filled with blood and profuse hemorrhage was feared, twice the usual amount of solution of epinephrine hydrochloride was added to the anesthetic, i. e., 2 drops per cubic centimeter, or 10 drops, half of the maximal dose for subcutaneous application (Poulsson). The injury is believed due to the effect of the epinephrine on the already weakened eye.

Acute Intoxication Due to External Use of Resorcinol.—Klem's case shows that even 20 Gm. of 50 per cent resorcinol paste, applied to an intact skin, may be dangerous.

Tuberculosis Among Medical Students.—Heimbeck et al. state that, among 183 medical students with known cutireaction prior to their hospital service, seven cases of tuberculosis were established during the hospital term, one among the eighty-eight with positive cutireaction, six among the fifty-one with negative reaction, and none among the forty-four with negative reaction, vaccinated with B C G.

Subphrenic Abscesses: Diagnosis and Treatment.—On the basis of his thirty-two cases, Dahl discusses the clinical development of subphrenic abscesses and their anatomic orientation, different types, diagnostic adjuvants and treatment.

CANCER OF THE BREAST

USE OF RADIUM AND ROENTGEN THERAPY IN CONJUNCTION WITH THE RADICAL OPERATION *

HUGH H. TROUT, M.D.

AND

C. H. PETERSON, M.D.

ROANOKE, VA.

It is well known that some English surgeons have recently abandoned surgery and are now advocating only the employment of irradiation in the treatment of carcinoma of the breast. In America also some well known radiologists are advocating irradiation to the absolute exclusion of surgery in this disease. On the other hand, there are surgeons in this country who believe irradiation actually stimulates cancer cell growth, and others who believe it lowers the surrounding tissue resistance so that cancer can develop more readily.

Certainly the report of the Committee on the Treatment of Malignant Diseases with Radium and X-Rays of the American College of Surgeons does not lead any one to hope for a cure to be derived from the exclusive [1] use of irradiation in the treatment of carcinoma of the breast.

Harrington [2] reviewed 1,859 cases from the Mayo Clinic and, after analyzing them, concluded that postoperative irradiation was of only little, if any, benefit.

Where such marked conflicts exist between honest and earnest men, the truth will probably be found somewhere between these two extremes.

In order to try to clarify our own mental uncertainty on this subject, we have reviewed as carefully as possible, with the incomplete and insufficient data at our disposal, the records of all cases of carcinoma of the breast in which operation was performed at the Jefferson Hospital, Roanoke, Va., between 1909 and 1930. Of course, there have been a number of inoperable cases seen during this period, which are not included in this series.

It was soon seen that no definite conclusions could be drawn from such a study of our limited experience, so we concluded to ascertain what was the general attitude and practice of other surgeons and radiologists as regards irradiation in association with surgery. With this in view, we sent a questionnaire to various surgeons and radiologists in this country and in Canada.

In other words, we have approached this question from three different angles: (1) our own clinical experience; (2) a review of the opinions of other surgeons, and (3) a review of the opinions of other radiologists.

CLINICAL EXPERIENCE

Our own clinical experience consists in analyzing as accurately as possible 341 cases of histologically proved carcinoma of the breast, all having had a Halsted radical operation. This series covers a period of about twenty years and is divided into three groups as follows:

1. From 1909 to 1920 there were 152 cases, and in this series only the radical operation, as advocated by the late Dr. Halsted, was done. At the end of five years, 32, or 22 per cent, of the patients were alive and apparently free from recurrences or metastases. In this group of 152 cases there were 8 patients whom we were unable to trace, and we assumed that these patients had died of cancer.
2. Starting in 1920, we began the placing of tubes containing radium in the field of operation and under the skin after the radical removal of the breast. We continued this method until 1924, and during this period there were 80 cases. Twenty-four, or 30 per cent, of these patients were alive and without recurrences after five years. In this group of 80 cases there were 5 patients whom we were unable to trace, and we assumed that these patients had died of cancer.
3. In 1924 we started the practice of adding high voltage roentgen exposures to the radical operation with the implantation of radium as previously mentioned. In this group there were 109 cases, only 18 of which have had their operations longer than five years. Ten, or 55 per cent, of these patients are alive and as yet without recurrences. Of course, this is far too small a number from which to draw any definite conclusions. In the remaining 81 cases in this group the time has been too short to be of any value, though, as far as we have been able to study them, there is apparently a marked decrease in the number of local recurrences and metastases.

In studying these cases, there are many factors other than operation and irradiation that have to be considered when attempting to estimate the relative value of any method. Chief among these undetermined factors are to be found the benefits resulting from the education of the public on matters pertaining to the necessity of early diagnosis and treatment of cancer. All surgeons are impressed with the fact that cases of carcinoma of the breast are being seen earlier, and therefore the results should be better.

It is possible that with increasing experience we are doing more thorough and complete operations as the years go by, but an honest effort has always been made to carry the dissection just as completely as the patient's condition permits in each case, and we do not believe this factor accounts for any marked improvement in our results.

No "typing" or grading has been done for a sufficient number of years to be of any comparative value. It has been known for many years that the histologic study of malignant growths was of great prognostic value. It is hoped that the classifications of Broders[3] and others, as well as the abstract cards of the American College of Surgeons, will be more universally employed. If this is done, surgeons will be able to make comparisons of methods which will be of some value. Any comparison of two series of cases without some such standard is of but little value, for, without this aid, reliance will be placed on possibly inaccurate impressions, and dependence on facts will be neglected in arriving at conclusions. The review of our own cases illustrates only too well this situation.

For a number of years we have felt that one large gland in the axilla, not associated with numerous small ones, gave a more favorable prognosis than numerous small glands in the axilla. In a recent communication from Dr. James Ewing, he states that "cancer localized in one large lymphatic gland is less malignant than one which rapidly spreads from one node to another. The very fact that it remains in one node shows that it is less active, or else that the filter is more effective."

We recall a number of cases in which *one large* gland in the axilla was removed during a radical operation, and these cases have done far better as regards both metastasis and recurrences than those in which there were numerous small glands. Perhaps this type of gland should be considered in estimating relative prognosis in different groups along with whatever histologic grouping is employed.

In our series there has not been one patient having a palpable supraclavicular gland who has lived as long as one year after such a gland was discovered, regardless of what was done.

It has been our custom to make histologic sections of glands removed from the axilla. We regret to state that our reports are not sufficiently accurate to give the relative percentage of malignancy found in such glands examined. However, we have been impressed with the fact that palpable glands in the axilla associated with a malignant growth of the breast does not necessarily mean that the axillary glands will show malignant invasion. Of course, in the vast majority of such cases these axillary glands are malignant.

We have also found the clinical index of Lee and Stubenbord[4] to be of much prognostic value. Our experience coincides with that of other surgeons relative to the poor prognosis in carcinoma in the young.

In 1922, one of us[5] called attention to the effects of pregnancy on the remaining breast after removal of the other breast for carcinoma.

Kilgore,[6] in 1921, pointed out the incidence of cancer in the second breast, showing that if a patient survives five years she is "from three to four times more likely to develop cancer in the second breast than a normal woman of the same age in either of her two breasts."

When we first started using radium in 1920, we placed most of the tubes containing the radium as close to the axillary vessels as we considered safe. We then placed the remainder of the radium around in different localities under the skin flaps.

Since the publication of Handley's oration, read before the Clinical Congress of the American College of Surgeons at Montreal in 1926, we have been trying to follow the suggestions he gave relative to the placing of these tubes. He places these so that they are near the course of the lymphatic trunk which accompanies the internal mammary artery, and also so that they lie close to the glands which are contiguous to this artery. Handley placed his tubes in these regions, since these were the points at which he noticed the recurrences.

Some years ago, Dr. Halsted attached considerable prognostic importance to the finding of a gland under the falciform fascia. This observation coincides with the experience of Handley. Handley[7] reported a most instructive case in which a nodule appeared in the second intercostal space five years after operation. Two years later, another nodule came in the third space. The fourth and fifth spaces were invaded at about four months' intervals. All of these nodules appeared along the line usually occupied by the internal mammary glands. Twelve years after operation, this patient died. Handley feels that, had radium been employed in conjunction with surgery at the first operation, this patient would not have died of cancer.

Handley classified his cases into three groups:

1. Cases in which the internal mammary glands are not infected at the time of operation.
2. Cases in which these glands are so infected.
3. Cases in which the glands are infected, and in addition, the disease has already spread beyond them to the other glands within the thorax.

He advocated the postoperative use of radium in group 2 but considers it superfluous in group 1 and ineffective in group 3.

We use radium with the operation as a routine, because we do not feel that we are able to classify our cases definitely, and, in addition to this, radium so employed certainly does not do any harm. As far as we are able to estimate, there has been no interference with the healing of the wounds.

The radium is screened with 0.5 mm. of silver and 1.5 mm. of brass. These tubes are then placed in the long pure gum rubber tube, which is kept in position by a ligature about the rubber tube above and below the enclosed radium tube. The amount used is either 50 or 100 mg. of radium in the form of two 25 mg. tubes, and four 12.5 mg. tubes. This distributes the radium over a distance of some 6 inches, and our method has been to leave orders for the tube to be pulled down 2 inches every two hours until removed. It will be seen that this varies the dose, depending on the height to which the tube is placed. Roughly speaking, the tube is entirely removed at the end of twelve hours, which would obviously give a dosage of 1,200 mg. hours when the larger amount of radium is used.

We have not employed preoperative irradiation largely because we have not been able to control our patients. In the few instances in which we tried it, the patients have either received some benefit or thought they had, and then delayed operation until there was definite glandular involvement. We have never practiced the method of giving one large massive dose before operation because in our hands such a dose produces too much nausea to permit an operation for several days, and this nausea starts a few hours after exposure to the high voltage therapy. Then, too, most of our patients with cancer of the breast are so apprehensive concerning the outcome of the operation that delay works a mental hardship.

[7] Handley, W. S.: Parasternal Invasion of the Thorax in Breast Cancer and Its Suppression by the Use of Radium Tube as an Operative Precaution, Surg. Gynec. Obst. **45**: 721 (Dec.) 1927.

There is apparently no doubt that irradiation heals the majority of surface epitheliomas and improves (if it does not cure) carcinoma of the cervix. In addition to these observations, some recurrences following radical operations for carcinoma of the breast disappear following irradiation. Occasionally one sees metastases decrease in size and in bone metastases the pain relieved, but we have never seen such a case "cured" by any type of irradiation.

Carnett and Howell,[8] in analyzing bone metastases in cancer of the breast, make the following statement:

> *The complete modern breast operation, especially along the* lines laid down by Handley, supplemented by irradiation, is seldom followed by external recurrence. In these days, patients exhibit skin nodules far less frequently than bone metastases.

If these observations are correct, it is reasonable to assume that sufficient and well directed postoperative irradiation will "kill" or retard the growth of any cancer cells that may inadvertently have been allowed to escape into the field of operation or any nearby extension which is impossible to remove with the complete operation. It is perfectly possible that insufficient dosage of irradiation will "fix" the tissues and make them "radioresistant."

Dr. James Ewing[9] stresses the importance of adequate doses:

> When one sees under the microscope the extensive changes, sometimes amounting to complete destruction of the mammary cancer by external radiation, one cannot escape the conclusion that preoperative irradiation of mammary cancer must be of value. Yet the doses delivered by the average radiologist or surgeon in these cases are ridiculously small. To produce definite results, one must deliver to the tumor at least two or three erythema doses, and this is very seldom accomplished. These tumors are resistant, and usually the best method is interstitial irradiation. After interstitial irradiation, we are now getting many breasts in which it is difficult to find any traces of carcinoma. Grounds for postoperative irradiation seem to me less clear and, again, the doses required must be considered. Assuming that small groups of cells remain beyond the operative field, full irradiation must inevitably damage such cells, but I fear that the doses ordinarily given are inadequate to accomplish much good. Yet, definite postoperative recurrences, visible and palpable, are often controlled by the ordinary radiologic treatment.

Many roentgenologists share the belief of this danger with him; hence it is important to be certain that sufficient dosage is given.

In visiting various hospitals and talking to different surgeons and radiologists, we find that the calibrating of x-ray machines is not as frequently done as physicists and x-ray manufacturers think necessary. Some years ago our attention was called to this possible error, and when we had a well known physicist calibrate our machine we were much shocked to find we had not known what dosages were being delivered.

The technic employed at the Jefferson Hospital in the postoperative roentgen irradiation is, briefly, as follows:

The intensity output is estimated annually by a competent physicist, the calibration being made in terms of r units. The erythema value of 970 r units is obtained with 360 milliampere minutes at 200 peak kilovolts, 50 cm. distance, and 5 milliamperes. The filters used are 0.5 mm. of copper and 1 mm. of aluminum.

Therapy is started in from seven to ten days after operation. The portals for the chest wall are 20 by 20 cm., but smaller portals are used in the axilla and supraclavicular region. Each area is treated daily with small doses, which usually cause little or no roentgen sickness. A daily radiation loss of 7 per cent is allowed for and the treatments are continued until the 970 r is given. The total time taken for this series is from fifteen to twenty days. The treatment series is not repeated. The initial and subsequent dosage may vary with the individual, but treatment is always carried to the skin saturation point.

We have tried the cautery excision of the breast but have had too few cases to draw any conclusion further than the fact that in our hands the healing was not as good as when the incision and dissection were done with the knife. From experimental work done by others, apparently, there is no doubt that actual heat kills cancer cells at a slightly lower temperature than it destroys most normal cells. Certainly in Dr. A. C. Scott's hands excellent healing is obtained, and were we able to obtain as good, we would add the cautery to our armamentarium.

To summarize our impressions from a study of our own cases, we feel that there are many factors which have produced improvements in our results, and that, while postoperative irradiation may be one of these factors, there are many others which have helped, chief among which is cancer education. We have seen no harm—mental, physical or financial—resulting from postoperative irradiation, and expect to continue its use until we obtain something better.

QUESTIONNAIRE SENT TO SURGEONS

We sent a questionnaire to 149 surgeons and received 138 replies. At the bottom of this sheet a space was left for voluntary remarks. One hundred and twenty-nine, or 94.5 per cent, had remarks to make, which shows that the question of irradiation in connection with radical surgery is a live subject with the vast majority of surgeons.

The following is a brief résumé of the various answers to the questionnaire sent to these surgeons, all of whom have membership in either the American Surgical Association or the Southern Surgical Association:

Question 1. Do you employ preoperative irradiation?

(*a*) Twenty-six employ preoperative irradiation as a routine.

(*b*) Eight employ preoperative irradiation occasionally; usually in advanced cases.

(*c*) One hundred and four never employ preoperative irradiation.

(*d*) Of the thirty-four who employ preoperative irradiation, all use postoperative irradiation also.

Question 2. Do you employ postoperative irradiation?

(*a*) Eighty-three use postoperative irradiation as a routine. Three use it not because of any faith they have in it but to prevent criticism, especially from the public, and have not seen ill effects from its use. One feels that he obtains marked benefit in 10 per cent of cases because such cases happen to be radiosensitive. He does not suggest any method of ascertaining which cases are radiosensitive and which ones are not. Concerning the remainder, there are too many widely divergent opinions for tabulation.

---

[8] Carnett, J. B., and Howell, J. C.: Bone Metastases in Breast Cases, Ann. Surg. **91**: 811 (June) 1930.

[9] Ewing, James: Personal communication to the authors.

(*b*) Fifteen never employ postoperative irradiation. Two because of bad mental effect on the patient. Three discarded use of irradiation before the advent of high voltage therapy. One feels that irradiation stimulates cancer growth. Two feel that it tends to make surgeons do less extensive operation. One has never used irradiation and claims that he does not feel that he knows anything about it. One discontinued its use following a report of the American College of Surgeons. The remaining five offered no explanation as to their reason for not using postoperative irradiation.

(*c*) Forty use it occasionally. Twelve use it only after recurrences have actually occurred. Twenty-three employ it when they think there are apt to be recurrences; e. g., glands in the axilla and adherence of growth to the chest wall. Three use it only when the family physician insists on its use. One uses it only after incomplete palliative operations in the aged. One uses it only in patients under 36 years of age.

Question 3. If so, x-rays, radium or both?

Of 123 using postoperative irradiation, 90 employ x-rays, one employs radium alone, and 32 use both x-rays and radium in the same patient. One surgeon calls attention to the possibility of insufficient dosage making the tissues become "roentgen fixed."

QUESTIONNAIRE SENT TO RADIOLOGISTS

We sent a questionnaire to 199 radiologists and received 130 replies. At the bottom of this sheet was left a space for voluntary remarks. Ninety-three, or 71 per cent, had remarks to make, which indicated that radiologists also are interested in the question of irradiation in association with surgery.

The following is a brief résumé of the various answers to the questionnaire which was sent to these radiologists, all of whom have membership in either the American Roentgen Ray Society or the Radiological Society of North America.

Question 1. Do you believe in fairly early and routine postoperative irradiation following radical removal of the breast for carcinoma?

(*a*) One hundred and nineteen answered in the affirmative.

(*b*) Eleven answered in the negative.

Of the 119 who answered in the affirmative, there were too many remarks made to be tabulated. Of the 11 who do not believe in postoperative irradiation as a routine, 7 employ x-rays for recurrences. One does not believe that surgery has any place in the treatment of carcinoma of the breast. One employs it when so desired by the physician. One stated that it was of no proved benefit and therefore never given. One had no remarks to make.

Question 2. If so, x-rays, radium or both?

Ninety-three used x-rays, 2 radium, and 24 both. Of course, this is explained by the fact that very few localities have sufficient amounts of radium to permit the giving of proper dosage.

Question 3. What dosage do you employ?

Ten employ from 100 to 124 kilovolt peak; thirty-one, from 125 to 149; twenty, from 150 to 179; forty-nine, more than 180. Massive, 33; repeated smaller doses, 75.

Question 4. Have you noticed any ill effects from irradiation, such as:

(*a*) Breaking down of incision? No, 112; yes, 7. From the various remarks made, it would seem that the general opinion is that such is due to improper dosage.

(*b*) Lung fibrosis? Eighty have not seen this; forty-six have seen it.

While the expression "lung fibrosis" was employed in the questionnaire, we are now convinced that this term was an unfortunate selection. Probably the expression "pluropulmonary reaction," as has been suggested, is a far more accurate description, as "lung fibrosis" implies permanent fibrotic changes. From the remarks that accompanied the replies, we are led to conclude that the large majority of men replying in the affirmative to this question really referred to a transient pleuropulmonary reaction. However, this is a dangerous sequela against which every known precaution should be employed.

(*c*) Nausea? All except nineteen have noted its presence.

Question 5. Have you ever seen irradiation stimulate cancer growth?

Fifteen thought that they had observed this phenomena. Five had seen it with sarcoma. Six had seen it with epithelioma. Four had seen it with recurrences after breast operations. The majority had seen this only with insufficient doses.

Question 6. Have you found "typing" based on histology of value in estimating "radiosensitivity"? Yes, 42; no, 52; no experience, 32.

It is a significant fact, as ascertained from these replies, that when the surgeons are opposed to postoperative irradiation, so also are the radiologists.

SUMMARY

From a follow up of our own cases, we find that our results have improved since the employment of postoperative irradiation, but we do not feel that such improvement is entirely due to the irradiation but rather to cancer education. However, we feel that postoperative irradiation is of distinct value and should be employed as a routine. We have seen no ill effects from postoperative irradiation, though we realize that unless a surgeon is careful he may relax in the thoroughness with which he does a radical excision, hoping that such irradiation will perhaps compensate for his dereliction.

We believe that the placing of tubes of radium *under the skin at operation followed* by sufficient and properly directed roentgen treatment is the best manner of giving postoperative irradiation.

Not enough time has elapsed to estimate the results of the newer roentgen treatment, but there are many indications that with the methods now in vogue the beneficial results of postoperative irradiation will be more definite.

It has never been proved that properly given postoperative irradiation is harmful; it is generally believed that irradiation is helpful in other parts of the body, and 89 per cent of the surgeons and 91 per cent of the radiologists who replied to a questionnaire assume that postoperative irradiation is beneficial as the adjunct to surgical treatment of carcinoma of the breast. Therefore we believe that the patient should be given the benefit of postoperative irradiation as a routine.

Jefferson Hospital.

The Importance of General Practice.—In the trend toward specialism the pendulum is swinging too far, and it is the duty of medical educators and leaders to indicate to their students the importance of general practice and the high profession attainments that are necessary for success in it. But this alone will not suffice. In the last analysis it is the attitude of the public which will determine the careers of many of our future medical men. If the public will but realize that it can have no greater asset than a close and continued personal relationship with a wise, sound, general adviser, it may rest assured that there will always be an adequate response to the call for service. In order to get the best type of medical men to turn to general practice, however, it is necessary for the public to understand that the qualifications for general practice are at least as high as those which are requisite for specialism, and to appreciate that the general practitioner is worthy of its respect and confidence.—Peabody, F. W.: Doctor and Patient, New York, Macmillan Company, 1930.

PROBLEM OF TUMORS OF BREAST FROM STANDPOINT OF GENERAL PRACTITIONER AND SURGEON

DIAGNOSIS, TREATMENT, PATHOLOGY AND PROGNOSIS *

ARTHUR DEAN BEVAN, M.D.
CHICAGO

I will discuss the problem of tumors of the breast from the practical clinical standpoint and give the conclusions which I have arrived at from my experience in my own clinic and in my laboratory. Tumors of the breast are very common. They occur in about three women in a hundred. They are comparatively rare in men. They occur about fifty to a hundred times as often in women as in men. For clinical purposes tumors of the breast can be classified in a very simple way.

In a surgical clinic in which during the year 300 women present themselves with the problem of tumor of the breast, 100 will not have a tumor at all, 100 will have a benign tumor, and 100 will have a malignant tumor.

Those who have no tumor at all form a most important group. They must be carefully studied, as they are an essential part of this problem. These patients fall into several groups:

1. Women who are alarmed about their having a breast tumor and come direct to the clinic; often they are in the fear of cancer because some relative or friend has had cancer. An examination shows no tumor.

2. Women who have consulted a general practitioner about their breast and have been told that they have a tumor and have been referred to the clinic for operation. Examination shows no tumor. The explanation here is simple. The woman herself thinks she has a tumor and the physician examines the breast and thinks that he can make out a tumor as he palpates a certain part of the breast. This often occurs when the woman has a normal but lobulated breast; palpating one of these lobules gives one the impression of a tumor, but with a little more experience with these cases the physician would learn that if he picked up the periphery of this breast at almost any point between the thumb and the finger it would give him the sensation of a tumor.

3. The woman in fear of a breast tumor who consults her family physician, who thinks she may have a breast tumor and refers her to a surgeon, who tells her that she has a tumor and needs an operation. Often the statement is made that an immediate operation should be done. Badly frightened, the woman or her husband desires another opinion and comes to the clinic. An examination at the clinic fails to find a tumor of the breast and it is evident that no operation is required. Here the explanation is more difficult. One can easily understand the woman's being unnecessarily alarmed and mistaken, and the family physician who has had a limited experience with tumors of the breast; but what about the man who poses as a surgical expert who has strongly advised an operation for breast tumor when none exists? The explanation must be ignorance, bad judgment or lack of sound ethics. I have seen repeatedly examples of all three. Some men pose as expert surgeons who are not in fact expert surgeons, and such a one can easily and honestly be mistaken. Again lacking good judgment, a consulting surgeon may advise the removal of a breast when no tumor exists, controlled by the thought that, although he cannot demonstrate a definite tangible tumor, one may exist and the operation is justifiable. The logic here is simple and clear. Tumors of the breast are definite, tangible and palpable lumps like a bean, an English walnut, an egg or an apple, and one should not strain his imagination or the eyesight at the end of the palpation finger and force the diagnosis of a tumor where none exists. Diffuse carcinoma of the breast may exist without a palpable tumor, but the other evidences are definite. A surgeon who lacks sound ethics performs an operation for the removal of the breast in a case in which the woman comes to him in the fear of cancer when no cancer and no tumor exist. One's first reaction to such a statement is that such a thing must be impossible; but I have seen so many cases and have investigated so many with care in which operations for the removal of the breast have been advised, when the most careful examination showed no tumor and when repeated examinations over a period of months and years disclosed no tumor, that I am forced to the conclusion that too many amputations of the breast are made on insufficient indications.

It is a fact that no one is infallible, that every one, even with the best intentions, makes mistakes; but certainly with the present knowledge of tumors of the breast there is little excuse today to remove a breast for tumor when none exists. In a case in which the surgeon is uncertain, an exploratory incision and the removal of a section for examination can be done easily and safely, and an unnecessary operation avoided.

Of the 300 women coming to the clinic, 100 have no tumor and require no operation. These women are, of course, grateful and most of them are satisfied with the simple assurance that they have no tumor and do not require an operation. A few of them who are in great fear of cancer come back repeatedly and need repeated and positive assurance that they have no cancer before they are finally convinced.

The other 200 women who are examined have a breast tumor. About half of these have benign tumors or benign conditions of the breast, and about one half have cancer. The essential benign tumors of the breast are fibro-adenomas and fibrocystic disease, the so-called chronic cystic mastitis of the breast. The malignant tumors of the breast are carcinomas in all but 1 or 2 per cent of cases and these are sarcomas.

The usual problem that must be solved in a woman who has a lump in the breast is: Is it a cancer, a fibro-adenoma or fibrocystic disease of the breast, or is it a granuloma such as tuberculosis? The correct clinical diagnosis can be made in more than nine tenths of the cases from the history and clinical examination.

How is the diagnosis made? The most satisfactory method of examining the breast is to have the woman in the erect or sitting position. The finding of a tumor with the woman in the recumbent position is more difficult. I have had a number of women tell me that they can feel the lump when they are standing up but not when they are lying down, and I have demonstrated this many times in examining for a breast tumor. The breast should first be examined with the flat of the hand by very gentle pressure and, if a lump is felt, the breast should be fixed with the left hand and the lump picked up with the thumb and forefinger of the right hand. Fixing the breast firmly with the left hand, one should

---

* Read before the Section on Surgery, General and Abdominal, at the Eighty-First Annual Session of the American Medical Association, Detroit, June 27, 1930.

now move the lump between the thumb and the forefinger of the right hand in the breast tissue as freely as possible to see whether it is freely movable or fixed and frozen into the breast tissue. This is the most important single piece of evidence that one can obtain in making an examination of breast tumors. The benign tumors are freely movable in the breast tissue. The malignant tumors are fixed and frozen into the breast tissue. On trying to move a carcinoma, one finds that it is so fixed in the breast tissue that the mammary gland moves with the tumor.

What is the explanation of this fact? The ancients called malignant tumors cancer—the crab—because like a crab it had legs extending into the tissues about it, and in fact this is true of cancer; for, extending for some distance beyond the gross primary lesion which one can see with the naked eye, processes permeate far out into the surrounding breast tissue which can be demonstrated with the microscope and these processes fix the cancer so that it is so frozen into the breast that when the lump is moved the breast tissue moves with it.

Far different conditions are found in examining a benign tumor of the breast. In examining an encapsulated fibro-adenoma one will find the tumor freely movable in the breast, often surprisingly movable, so that it can be moved an inch or two without any perceptible movement of the breast tissue, and usually, but to a more limited extent, the same free movement is found in examining a cyst of the breast and in cystic disease of the breast where the lump is not encapsulated. Although they are not encapsulated, they are not frozen into the breast by processes extending out from them as in a cancer; and because of that fact fairly free movement of the cyst in the breast can be obtained.

In making an early diagnosis of cancer of the breast when the lesion is still limited to the breast, the problem is solved by determining whether it is fixed and frozen into the breast or movable. The same fundamental facts that produce fixation in a cancer produce two other clinical facts of great value in making the diagnosis of cancer of the breast: dimpling of the skin over the lump and retraction of the nipple. Women often come to me for examination of the breast saying that they have discovered a dimple in the breast which they have never seen before; this almost invariably means cancer.

The cases of cancer of the breast which can be cured by operation are those in which the lesion is still limited to the block of tissue which can be removed at the operation, and in these cases the only pieces of evidence that can be obtained are the existence of a lump fixed in the breast tissue. The old textbook symptoms of cancer of the breast, pain, enlarged glands in the axilla, fixation of the breast to the thorax, evidences of carcinomatous cachexia and enlarged glands above the clavicle, tell all too plainly the story of an advanced process which may be palliated but not cured.

In making a differential diagnosis between fibro-adenoma and fibrocystic disease of the breast, one may find much difficulty. I am often uncertain, especially in the case of a single lump, whether I have a solid or a cystic tumor to deal with.

One of the most interesting and common conditions of the breast is still a pathologic problem. I refer to the chronic cystic mastitis of Koenig, the maladie cystique of Reclus, the cystadenoma mammae of Schimmelbusch and the fibromatosis of Fragenheim and Dietrich. This condition furnishes, next to carcinoma, the greatest number of breast cases. Koenig believed that it was due to chronic inflammation of the breast with resulting cyst formation; Reclus believed it was a cystic disease of the breast and not neoplastic; Schimmelbusch regarded it as neoplastic, and the process is often spoken of as Schimmelbusch tumors; Fragenheim and Dietrich regard the process as a senile or presenile involution change due to hormones from the ovary. This last conception seems very plausible.

From the standpoint of the clinical surgeon I believe that it must be discussed with breast tumors and I have described it under the head of fibrocystic disease of the breast. The process includes the large solitary cyst, the multiple cysts in one or both breasts and a wide variety of conditions between these extremes. It must also be made to include a chronic fibromatosis of the breast with little evidence of cyst formation.

From the pathologic standpoint the term fibrocystic disease of the breast probably describes better than any other term the true nature of the process.

For clinical purposes the best classification of tumors of the breast is into benign and malignant, as in the accompanying tabulation.

Classification of Tumors of the Breast

Benign	1. Fibro-adenomas, which consist of	Pericanalicular and intracanalicular, with the special cauliflower type called cystosarcoma phyllodes; intraductal fibro-adenoma
	2. Papillomatous cysts: true tumor of the breast resembling true ovarian tumors	[illegible] rare in the author's clinic
	3. Fibrocystic disease of the breast or chronic cystic mastitis	Single blue dome cyst; multiple cystic disease; chronic fibromatosis of breast
Malignant	1. Sarcoma, probably forming less than 2 per cent of malignant tumors	Spindle cell and round cell, very few giant cell; many sarcomas are more or less cystic
	2. Carcinoma, forming more than 98 per cent of malignant tumors	1. Simple carcinoma 2. Diffuse carcinoma 3. Medullary carcinoma 4. Colloid carcinoma 5. Adenocarcinoma 6. Carcinomatous cysts 7. Paget's disease

BENIGN TUMORS

The fibro-adenomas are easily recognized. They are encapsulated, freely movable and hard on palpation. One cannot differentiate clinically the pericanalicular from the intracanalicular; in fact, in some tumors both pericanalicular and intracanalicular tissue can be seen in the same field. The special and unusual clinical picture is the cauliflower type, the improperly called cystosarcoma phyllodes, which is not a sarcoma at all but a benign tumor of the intracanalicular type, which grows rapidly like a cauliflower and by pressure necrosis sometimes produces an ulceration of the overlying skin permitting the tumor to grow out as an ulcerating necrotic mass, producing the impression of a fungating malignant tumor. The term cystosarcoma phyllodes should be dropped. The better term would be cystofibroma phyllodes or fungating intracanalicular fibro-adenoma. These cases are not especially common. The safe way to handle them is to make an exploratory incision under a general anesthetic and have a frozen section examined at once to determine the diagnosis. The condition demands simply the thorough removal of the tumor and not a radical amputation of the breast.

Papillomatous Cysts; Cystadenoma of the Breast.—These are true tumors and are to be distinguished from retention cysts and the cysts that are so common in chronic cystic mastitis, just as multiple follicular cysts of the ovary are to be distinguished from true ovarian tumors. Many of these have papillomatous ingrowths projecting into the cyst cavity. These may produce bleeding from the nipple. These papillomatous cysts may be malignant or may begin as benign and become malignant later. These true cystic tumors of the breast are not common. One will see more than ten cysts of the breast due to chronic cystic mastitis to one true cystic tumor of the breast.

One form that is of especial interest is a papillomatous tumor or a fibro-adenoma in a milk duct which gives rise to a bleeding nipple and which can often be located with the tip of the finger and either felt or located by producing bleeding from the nipple by pressure over the tumor.

The most common form of benign lump in the breast is produced by the process called chronic cystic mastitis, fibrocystic disease of the breast, fibromatosis of the breast. This, as I have already stated, is not inflammatory or neoplastic but probably an involution change in which fibrous tissue and retention cysts are produced. There may be but a single large blue dome cyst, surrounded by a few satellite cysts; there may be an extensive cystic disease involving a large part of the breast or there may be a general fibrosis of the breast with small cysts sparsely placed in the tissue. This process is probably initiated by hormones from the ovary; the hormones that produce the changes in the breast in menstruation and pregnancy. The process is a senile or presenile involution change. It has been my practice to operate on these benign tumors and remove them by a local resection which I shall describe more in detail, especially for the purpose of making a definite diagnosis.

MALIGNANT TUMORS

Sarcoma can be dismissed with a few words. Sarcoma is so rare that even in a busy clinic it is seldom seen. Probably less than 2 per cent of malignant tumors of the breast are sarcomas. The old statistics of Billroth and Gross on breast tumors cannot be accepted today. They thought that more than 80 per cent were carcinomas, about 9 per cent sarcomas and about 9 per cent benign. Statistics today are that more than half of breast tumors are benign, less than half malignant and only about 1 or 2 per cent sarcomas.

Most of the sarcomas are spindle-cell, some round and a few giant-cell; about one half of the sarcomas are more or less cystic. They should be handled by the same radical operation as carcinomas. In their early development they may be difficult to differentiate from benign tumors. A definite diagnosis can be made only by the microscopic section.

Clinically, the most important tumor of the breast is carcinoma. One must be able to recognize several clinical forms:

First, simple carcinoma with a definite single palpable frozen-in tumor.

Second, diffuse carcinoma involving the breast widely, often so diffuse that no palpable tumor can be made out. The skin is edematous from lymphatic obstruction producing a lymphedema and looks like a pig-skin saddle. The mammary gland is larger than normal and often looks as though inflamed, and it is often mistaken for an inflammatory lesion.

After one has seen a number of such breasts the site of a diffused carcinoma, the diagnosis is not difficult; the prognosis is bad. The cancer of the breast in which there is a definite palpable single tumor may be either hard or soft or cystic or an adenocarcinoma or be the site of mucoid degeneration. These differences are not of great interest or importance clinically and are usually determined on microscopic examination which must, of course, always be made.

Another form that must be recognized clinically is the condition called Paget's disease of the breast. This is not uncommon. It has a distinct clinical picture which can be easily recognized after it is seen a few times. There is usually no palpable tumor in the breast, but in advanced cases there may be one. The nipple is the site of an eczematous skin lesion; the nipple is retracted and covered with a red weeping integument which bleeds easily. It is to be differentiated from simple eczema, which is not as a rule of as long standing and which should disappear under proper treatment. It has given rise to much controversy since it was first described by Paget in 1874. Its pathology is now thoroughly understood. It is a carcinoma beginning in the milk ducts and extending to the skin around the nipple, and the eczema is secondary to the carcinoma. The carcinoma is not secondary to the eczema. No mistake should be made in the handling of this condition. It should not be handled medically or with roentgen treatment but should be treated as any other cancer of the breast by radical amputation.

The operative technic for tumors of the breast has become standardized. The benign tumors should be removed by local excision, the malignant by the radical breast operation. One cannot always be sure in a given case, however, whether one has a benign or a malignant tumor to deal with and this fact must, of course, be first determined. One must always be prepared in a given case to do either a local or a radical operation.

The patient is told before the operation that the diagnosis cannot be determined with absolute certainty except by a microscopic examination.

The patient is prepared for operation. I prefer ethylene as the anesthetic. Ethylene should never be used, however, unless the operating room has been properly grounded to prevent static. With this proper grounding, ethylene is just as safe as the use of gasoline in one's automobile. More than nine times out of ten the clinical diagnosis is sufficiently clear to warrant the surgeon in proceeding at once to do either a local excision or a radical operation. In possibly one case out of ten the experienced surgeon is uncertain and an exploratory incision down on the tumor is necessary. In almost all of these cases—say in 95 per cent—the character of the tumor can be determined from its gross appearance on section. In a case in which there is doubt, a frozen section is made at once and a microscopic examination obtained. With such a scheme of procedure the surgeon can safely decide on either a local or a radical operation on the basis of the evidence obtained.

In operating on benign tumors I almost always employ Warren's incision made in the fold under and to the outer side of the breast, turn the breast upside down, expose the tumor from beneath, remove the tumor by clean-cut sharp dissection, removing an elliptic mass containing the tumor, sew the incision in the breast together with catgut, close the superficial fascia with catgut, and close the skin incision with a fine catgut subcuticular stitch. This makes a fine closure and a barely visible scar. These cases should all be drained with soft collapsible rubber tubes for about three days, as there may be some bleeding and a considerable amount of primary wound secretion. Occasionally a benign tumor is better removed by an incision directly through the skin over the tumor. Here the incision should radiate from the nipple. The same incision should be employed in the doubtful case in which there is uncertainty as to diagnosis.

In doing the radical operation for cancer of the breast there are certain definite surgical principles that must be followed. The entire breast must be removed, the overlying skin widely, the underlying pectoralis major, and if necessary the minor, and the axillary space of the fat and lymphatic glands cleaned out. No fixed set incision should be adopted, but the incision must be planned so that as near as possible the primary lesion will be in the center of the block of tissue removed.

The incision should be planned and can be planned so that in almost all cases a skin closure can be made without tension, making skin grafting seldom necessary. Patients should be sitting up the day after operation and leave the hospital in from ten to twelve days. The mortality is very low. It should not exceed 1 per cent.

PROGNOSIS

What is the prognosis in operations for tumor of the breast? In benign cases there should be no mortality and no recurrence. To be sure, other fibroadenomas may form in that breast or in the other breast, and there may also be a recurrence or a continuation of the same process when a cystic tumor in chronic cystic mastitis has been removed. One seldom sees, however, a carcinoma develop in a breast from which a tumor proved to be benign has been removed. I believe that there is little likelihood of a benign tumor degenerating into a carcinoma. There is one form of tumor, the papillomatous cyst, which is like the papillomatous cyst of the ovary and which, if it is early removed and completely removed, seldom returns, but which may, if it is allowed to remain, develop into a malignant papilloma.

What is the prognosis in cancer of the breast today? In the cases in which the cancerous disease is limited to the breast and the block of tissue removed at operation and the axillary glands are not involved, the prognosis is excellent, probably 75 per cent of cures. In those, on the other hand, in which the axillary glands are involved, it at once sinks to less than 10 per cent of cures; and in the cases in which the glands above the clavicle are involved, it sinks almost to zero. As the patients come to the clinic, in most of them at operation the axillary glands are found to be already involved, and these cases reduce markedly the percentage of permanent cures.

What about roentgen treatment? I believe in a thorough course of roentgen treatment after the operation; not in massive doses but in very moderate doses continued for some time. I have seen great injury done by massive doses—fibrosis of the lungs and extensive burns.

Cancer of the breast can be cured. It can be permanently cured in the cases which are recognized early and in which operation is performed early. I am thoroughly converted to the position that the campaign of education that is being carried on by the Society for the Control of Cancer and by the profession as a whole is leading to earlier diagnosis and more cures, and should receive the support of the entire profession.

122 South Michigan Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. TROUT AND PETERSON AND DR. BEVAN

Dr. Dallas B. Phemister, Chicago: I believe that the indications for radical removal of carcinoma of the breast and *neighboring metastases should* be pushed to the extreme. The operation is neither a dangerous nor a particularly discomforting one. Occasionally it will result in a cure and usually it will prolong life. Also, the conditions for irradiation are more favorable. I want to emphasize what Dr. Bevan said about chronic cystic mastitis. The condition is not a neoplasm and should not be treated by operation. Single lesions may be operated on because of uncertainty of diagnosis, but once the diagnosis is established the subsequent recurrences should be left alone.

Dr. Martin Tinker, Ithaca, N. Y.: A recent paper by Forssell of Stockholm gives a report of the results of the efforts of a nation to combat cancer. He called attention to the fact that certain forms of malignancy are best treated by surgery alone, others by surgery in combination with irradiation, and still others by radium or x-rays alone. It is gratifying, I think, to see that Drs. Bevan, Trout and Peterson, and Phemister all believe that these measures have value, that the chances of cure are being increased by use of radiation in connection with surgery. No one questions, I think, that, in dealing with breast cancer, radical operation is the first thing to consider. If, however, the chances of permanent cure can be added to considerably by the use of radiation, it surely should be considered. For fifteen years I have been combining surgery with radium, more particularly; not that I use radium myself; I think the use of radium or radiology belongs to a group of men who devote their entire time to that line of work; but if radiologic work is turned over to men who are expert, I believe thoroughly that it gives the patient a better chance. Forssell emphasizes this point in his paper that in the institute at Stockholm the best results have been obtained by men who have had experience over considerable periods of time in using radium and x-rays in the treatment of these conditions. A second point is that in many instances a large amount of radium is necessary to produce the best results. Another point that has not been mentioned, but in which many are interested, is the question of electrosurgery. I have been experimenting with electrosurgery for fifteen months, and it seems that sealing lymphatics and blood vessels does add somewhat to the prospect of permanent cure in these cases.

Dr. Jacob H. Vastine, Philadelphia: Recently Pfahler and Parry reviewed 977 cases that had been treated in the office. In the postoperative group, in which radiation therapy was instituted within three weeks after the operation, 62 per cent were alive after three years, and 55.5 per cent were alive after five years. This includes all postoperative cases, both those with and those without glandular involvement at operation. Of the patients who had only the primary lesion and no evidence of metastases in the axilla, supraclavicular glands or elsewhere, there were 96 per cent alive after three years and 87 per cent alive after five years. These are microscopically proved cases and the patients are alive. There is no opportunity for the personal equation to creep in. I feel that these results are gratifying. Dr. Bevan has quoted 75 per cent surgical cures. My five-year cures are 87 per cent. This would indicate that 12 per cent has been added by postoperative irradiation, and I think that that justifies the employment of irradiation as a routine postoperative measure. Dr. Bevan has said that 10 per cent of the cases with axillary metastases can be cured surgically. In my group, those in which axillary metastases were microscopically present in the axilla, with the breast and axilla removed surgically, followed immediately by postoperative irradiation, 63 per cent were alive after three years and 55 per cent were alive after five years. This also would seem to me to indicate that a patient's chances are enhanced by postoperative irradiation. These results cannot be duplicated by a standardized technic and with treatments given in a perfunctory manner by a technician. Each case must be studied carefully, intelligently and individually. The rays must be properly directed and the dosage properly calibrated so that the maximum therapeutic effect is obtained without harm to skin or lung.

DR. F. F. LAWRENCE, Columbus, Ohio: Cancer is no respecter of persons. Cancer of the breast occurs in both male and female. It is no respecter of age. The fallacy of teaching that only people past 35 develop cancer should be emphasized. Cancer in the beginning is painless. Hence a painless lump in the breast should be given careful and thorough attention to make sure that it is not cancer. Metastases are aided by, if not caused by, rubbing or manipulation. Hence, a breast with a lump in it should never be rubbed, massaged or otherwise manipulated. Consequently, the lotion, ointment or other application applied to a breast with the hope of causing absorption should be tabu. Enlargement of the lymphatics is a positive evidence of metastasis. Hence, to wait for a diagnosis of cancer of the breast until there is axillary enlargement is to wait too long. There is no such thing as a cancer cure, that is, a positive cure for cancer, at the present time. The public should be educated to the fakery and dishonesty of all claims of cancer cures. It is to be hoped that research work may soon be effective. What is known about cancer is that it is not a germ disease, that it is not infectious, that it is not hereditary, and that it develops after long continued irritation. Hence, all forms or sources of irritation should be guarded against. It is not known why irritation produces proliferation of epithelial cells in one case, carcinoma and a reversion to embryonic cells in the other, and sarcoma, but it is known that it does. Being painless in the early stages, it has caused many patients to go beyond the operative stage. Hence, it is a safe position to take that every lump of the breast, no matter how small, should be removed and examined. If found benign, well and good. If found suspicious, the breast should be removed. If found positively carcinoma, the radical operation is indicated.

DR. ARTHUR DEAN BEVAN, Chicago: In regard to the anesthetic, I believe that ethylene is an ideal anesthetic for a breast amputation. I like it better than nitrous oxide, because a larger amount of oxygen can be used, and I like it much better than ether. The patient can be kept anesthetized with 20 per cent of oxygen. Ethylene can be used with just as much safety in the operating room as gasoline can be used in the automobile. There are these things, however, that must be recognized and observed: that there must not be any naked flame or cautery in the room, and that static must be done away with. Eight explosions occurred during a period of years when I was beginning to use ethylene, five from ethylene, two from nitrous oxide and one from ether; fortunately, none of these were serious and no patient was injured. In the last two or three years since static has been eliminated, more than 10,000 ethylene anesthesias have been employed without any trouble whatever, and there has been no further trouble with explosions from nitrous oxide and oxygen and ether in the machine. The method is simple. It costs about $35 to equip an operating room. The surgeon operates on a steel mat measuring about 10 by 12, made of rustless steel. This is tied up to the plumbing, a chain from the operating table to the steel mat and from the anesthetizing machine to the steel mat. Then special precautions are taken in regard to the anesthetizing machine itself so as to eliminate static charge from the rubber tubing—steel inside and outside of the tube, and a thin coat of mail around the bag. One thing done in almost all cases unless the evidence is very conclusive is that the woman is brought to the operating room with the knowledge that she is to be operated on for tumor of the breast. The patient is told that the exact character of the tumor cannot be determined until after the operation. It is true that with a little careful study the surgeon who is familiar with gross pathology can probably tell in 95 or, as Francis Carter Wood says, in 98 per cent of the cases the difference between a malignant and a benign tumor on gross section. As a matter of fact, the gross section is much more determining, as a rule, than a frozen section. However, I always use a frozen section whenever there is any indication for it. But carcinoma is typical: there is the same difference between a carcinoma and a fibroadenoma that there is between a turnip and a tomato, and there is no difficulty in ordinary cases in making the differentiation.

DR. HUGH H. TROUT, Roanoke, Va.: The one factor that has contributed most to cancer results is cancer education. The percentages that Dr. Peterson and I gave include all the cases, regardless of whether the axillary glands were involved or not. Speaking of the axillary glands, we failed to mention something that is interesting to us, and somewhat important. For many years we have made serial sections of all the axillary glands in association with cancer of the breast. We have found that about 10 per cent of those which we were able to palpate do not show malignancy in serial section; 90 per cent of them do. It is rather interesting that some of these palpable glands in the axilla are not malignant. Dr. Vastine brought out an important point, one which was mentioned in the paper, and that is the absolute necessity, in order to have irradiation done properly, whether preoperatively or postoperatively, of having it done by a competent radiologist.

SURGERY IN DERMATOLOGIC PRACTICE *

AND
MERLIN J. STONE, M.D.
NEW YORK

Dermatology has evolved from a morphologic study of skin diseases and abnormalities, distinct from medicine and surgery, to the modern conception of cutaneous medicine in which the skin is considered as one of the important organs of the body in intimate physiologic relation with the general economy. This evolution has been accompanied by radical changes in diagnostic and therapeutic methods. The recognition of the relation of many morbid conditions in the skin to underlying disease processes necessitates the application and adaptation to dermatology of many of the modern diagnostic and therapeutic procedures developed in the fields of medicine and surgery during the dramatic scientific progress of the past few decades. It is therefore evident that the dermatologist of today should have a broad training in general medicine and surgery as a foundation for his special training.

From the standpoint of therapy of many cutaneous conditions, surgery in its various forms has long been and still is one of the most useful and effective procedures. Drainage of abscesses by incision and the destruction of skin lesions by cautery are described in the earliest medical literature. Failure to utilize, develop and adapt to the specialty of dermatology the spectacular scientific progress in surgery would seem to be as detrimental as to neglect any of the other valuable therapeutic agents, such as radiation therapy or chemotherapy.

Inquiry indicates that dermatopathology forms a rather meager portion of the surgeon's study of surgical pathology. In fact, dermatopathology is so slighted by the general pathologist that dermatologists have been obliged to develop this field for themselves. With few exceptions, the only authoritative experts on dermatopathology in this country are practicing dermatologists who have made a special study of this phase of pathology. A comprehensive knowledge of the pathology of the conditions treated is just as important to the physician who does cutaneous surgery as to one who operates in other fields.

---

* The fields of plastic surgery and cosmetic surgery are not considered in this paper.

* From the Department of Dermatology and Syphilology of the New York Post-Graduate Medical School and Hospital.

* Read before the Section on Dermatology and Syphilology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

Some dermatologists do not desire to do cutaneous surgery and have not acquired training for it; but even they should be sufficiently grounded in surgery to recognize its indications and what may be accomplished by it. Not all otologists or ophthalmologists do the surgery called for in their respective special fields, but many of them do and these men are usually better trained and experienced in this work than general surgeons.

As a matter of fact, all physicians who limit their practice to dermatology and syphilology have always used some forms of surgery regularly in their practice in the office and in the clinics and will continue to do so. In textbooks on dermatology the surgical procedures of drainage of pyogenic infections, curettage, and the destruction of neoplasms and other tissue by cautery, by surgical diathermy, by electrolysis, by refrigeration and by escharotics, are not listed as surgery although the surgeon utilizes many of these procedures. Many dermatologists use the scalpel for minor operations in the office. Most of the surgery required in dermatologic practice is minor surgery which can be well performed in the office under local anesthesia provided a properly equipped surgical room is available and the dermatologist possesses surgical training and experience.

In view of the fact that surgery is and always has been an integral part of therapy in the practice of dermatology, more than casual attention should be given to it in the presentation of dermatology in medical schools and during the period of postgraduate special training. It is not uncommon to encounter physicians who have entered the specialty of dermatology with little interest and no experience even in minor surgery. Usually these men have planned early on entering the specialty and have not done any general practice. They have not had it brought to their attention that minor surgery in its various forms is used in the everyday practice of the dermatologist. Owing to lack of interest, some of these men have avoided surgical experience. As emphasized by their advisers, they have served internships in services limited to internal medicine. This is excellent preparation, as far as it goes, for the practice of dermatology, but these men now feel the lack of surgical training and experience. If not more than two years is to be spent in hospital training, it *would seem that a rotating* internship would form the better foundation for dermatologic specialization. This rotating service should include laboratory, medicine and surgery. Additional experience in internal medicine is naturally desirable and valuable, as is also some training in other specialties, such as pediatrics, gynecology and obstetrics. In order to be a capable guide for his patients, the specialist in any field should be familiar with the scope of the other specialties. With such broad training, his opinion in consultations is more likely to be sound. Of course, a period of general practice gives valuable practical experience which cannot be obtained in any other way.

The department of dermatology and syphilology of a clinic which makes a point of research and postgraduate teaching should have a well equipped surgical unit. By close cooperation of the surgical unit with the unit of dermatopathology aided by photographic records and follow up of the cases, valuable research may be accomplished. Gross and histologic study of excised neoplasms and other lesions, together with photographs and careful clinical studies of the patients, offers an admirable means of bringing order out of chaos in the understanding of many confusing dermatoses. Such a unit furnishes a means of increasing the knowledge of cutaneous surgery and also an opportunity for the postgraduate student to gain experience in this field. Lectures and demonstrations covering this subject should be conducted by the teaching staff and should include consideration of surgical dermatopathology, indications, technic, postoperative care of wounds, and prognosis. The postgraduate student should be given an opportunity to operate under supervision. All forms of surgery performed in the dermatologic department, such as cautery, refrigeration, electrolysis, surgical diathermy, use of escharotics, injection of varicose veins and scalpel surgery, should be performed in the surgical unit under capable supervision. Surgical procedures utilizing physical agents for the destruction or removal of tissue are probably more functions of the surgical unit than of the unit of physical therapy.

The operations indicated in dermatologic conditions come usually under the arbitrary classification of minor surgery, but this in no way lessens the responsibility of the operator. Even minor operations occasionally result in the tragedy of undesirable or serious complications, or even in the death of the patient. It follows that surgical operations should not be attempted by the dermatologist or by any other physician unless the operator possesses surgical experience and unless proper facilities are available for safe and scientific performance of the operation. The operator should be able to judge the ability of the patient to withstand the shock of the operation. He should know how to minimize shock and how to deal with the various types and degrees of circulatory disturbance, should any of these occur during the operation. This applies to operations by surgical diathermy as well as to operations performed with the scalpel.

A thorough familiarity with the use of local anesthesia together with facility in its administration is essential and is obtainable only by practice and experience. If gas anesthesia or any other general anesthesia is used in the office, it should be administered by a trained anesthetist. General anesthesia is occasionally necessary in minor operations on children and even on adults.

Maintenance of asepsis is almost as important in *minor surgery as in major surgery.* It is therefore mandatory that dermatosurgery in the office or clinic should be done in a properly equipped room and that sterilized supplies and instruments be available. Competent assistance is desirable for maintaining asepsis during the operation. Careful preparation of the skin and protection of the operative field by sterile sheets and towels should not be neglected.

Scalpel surgery has some advantages over other methods of dealing with certain cutaneous lesions which should logically make it the method of choice. It should always be considered when the removal or destruction of a lesion is indicated. The wounds heal more rapidly and the cosmetic result is usually better. These are important considerations, especially to the patient who deplores the time consumed and the expense necessary for numerous office treatments and dressings. The excised tissue may be studied microscopically to prove or disprove the diagnosis and to check up on the complete or incomplete removal of the lesion. Sometimes lesions that are apparently benign prove to be malignant.

We believe there is a tendency to use surgical diathermy too much as a matter of routine in the destruction of cutaneous lesions. Too often the destruction is not thorough enough or, on the other hand, there is excessive destruction of normal tissue with unnecessary scarring and prolongation of the period of healing. Often, in potentially malignant lesions, the tissue destroyed or removed is not checked microscopically for diagnosis or is so damaged by the high frequency current as to render a histologic diagnosis impossible.

In the following list are some of the many cutaneous lesions for which scalpel surgery should be considered as a method of removal even though it may not be the method of choice:

- Biopsies to prove or establish diagnosis.
- Benign neoplasms:
  - Adenoma.
  - Fibro-adenoma.
  - Fibroma.
  - Lipoma (circumscribed).
  - Neuroma.
  - Neurofibroma.
  - Nevi of various types.
  - Xanthoma—xanthelasma.
  - Fibro-xanthoma.
- Cysts of various types:
  - Sebaceous cysts.
  - Dermoid cysts (subcutaneous).
  - Mucous retention cysts.
  - Synovial cysts.
- Malignant neoplasms:
  - Sarcoma of various types.
  - Epithelioma.
  - Melanoma.
- Granulomas occupying small areas:
  - Lupus vulgaris.
  - Tuberculosis verrucosa cutis.
  - Blastomycosis.
  - Actinomycosis.
- Sequelae of irradiation:
  - Ulcers.
  - Atrophic or sclerotic tissue.
  - Keratoses.
  - Epithelioma.
- Verruca plantaris and other verrucae.
- Chronic ulcers.
- Diseased or deformed toenails and fingernails.
- Scars—unsightly and interfering with function.
- Tattoo—small.

In addition, small plastic operations and skin grafts, especially Thiersch grafts, may be performed in the office under local anesthesia if the operator is experienced in these procedures. Keloids (large, old and thick) may be excised or pared down and recurrence prevented by subsequent roentgen or radium therapy.

The dermatologist should be experienced with all surgical methods, physical and scalpel, and with all conventional methods of treatment. In this way he will be able to select the method that offers, in his judgment, the best result in the individual case, rather than always using the one method with which he has had experience. Such choice of method will eventually lead to improved statistics. A broad training of this kind makes dermatology more comprehensive.

We believe that the surgically trained dermatologist can obtain better results in some cutaneous conditions than does the general surgeon—i. e., keloid, moles, and the like—because in order to obtain superior results in such conditions it is necessary to know clinical dermatology, dermatopathology and surgery. We predict that the dermatologist of the future will possess adequate surgical ability. It is to be hoped that the dermatologist will not make the mistake in surgery that has been made in radium therapy. He now knows that he should not attempt to treat a really malignant neoplasm with an inadequate amount of radium and with inadequate experience and equipment. Of course, major surgery will never be a part of dermatology any more than is major high voltage roentgen therapy.

200 West Fifty-Ninth Street.

ABSTRACT OF DISCUSSION

Dr. Fred Wise, New York: The various points brought out by Drs. MacKee and Stone are so clear-cut and obvious that only an elaboration of their views is indicated in a discussion of the subject. To keep pace with the rapid advances in the practice of dermatology, the successful dermatologist of today must evidently be "on his toes" from dawn to midnight. It must be borne in mind that a great many of the routine therapeutic procedures in offices and clinics are pure surgical operations which have become commonplace only through familiarity and constant repetition. I am thinking particularly of intravenous and intramuscular injections, curettage, electrolysis, monopolar desiccation, and the like. These are all relatively simple operations, but they all require knowledge and skill of a high order. The removal of tissue for microscopic examination, especially from the mouth and the genital regions, and from the vicinity of the eye, must never be relegated to the inexperienced youngster with an excess of confidence in his skill. This refers especially to work in clinics, where younger men should be on probation until they acquire a sufficient amount of experience in minor surgical technic. We have established a rule at our clinic, calling for experience on the cadaver, in the technic of cisternal puncture, before permitting this operation to be carried out on our patients, and I think it is a wise rule and that it should apply as well to spinal puncture technic. The injection treatment of varicose veins is being taken up more and more by dermatologists, chiefly because of our frequent contact with varicose eczemas, ulcers, and chronic lichenification of the legs. I need not emphasize the fact that this type of work should never be undertaken by any one who is not possessed of considerable skill in minor surgery, as unskilled work may result in grave consequences. The surgical treatment of malignant lesions especially of the face, and particularly near the eye and the lips, calls for a well grounded and thorough knowledge of minor surgical technic. If undertaken by the unskilled, ectropion of the eyelids and distortion of the mouth may often result. With regard to the surgical treatment of melanotic lesions, I believe that the responsibility should always be shared with one or more surgeons of recognized ability and sound judgment. These lesions belong on the borderline between minor and major surgery.

Dr. Joseph R. Grindon, St. Louis: Some of our members whose brains extend to the tips of their fingers can probably do surgical work effectively in dermatologic cases. Most of us, however, who are not using the strict surgical precautions every day, and who have not the opportunity to keep in training, should let these things alone. I believe this is a very good rule.

Dr. Everett S. Lain, Oklahoma City: The authors are to be complimented for calling attention to the fact that the successful dermatologist should be trained in minor surgery. In recent years he has made great progress in radiotherapy, which has brought him in touch with superficial malignant growths. The dermatologist has realized that many of these lesions need both irradiation and surgery. Drs. MacKee and Stone have well called attention to those cases in which surgery is indicated. I wish merely to emphasize the work that dermatologists are now doing with the late models of the endotherm machines or bipolar diathermy. This technic is considered applicable to many of those lesions needing both radiotherapy and surgery. The machines are convenient and rapid in operation and as a rule their use results in an almost bloodless field. This technic is being used only after proper irradiation with radium or roentgen ray. I would further emphasize the precautions mentioned by Dr. Wise regarding melanomas. I consider that this type of tumor should always be treated surgically. I favor some form of coagulative treatment, either the surgical diathermy or bipolar coagulation. The principal disadvantage of such treatment is the slowness of healing. In some instances the sutures do not hold because of the extensive devitalization of tissue that results in retraction and delayed healing. Experience has shown that, through the use of nonabsorbable sutures placed far back from the border, satisfactory healing can be obtained. This difficulty, I understand, is now being overcome by a machine that does not devitalize the tissues for more than 1 mm. from the incision.

Dr. F. J. Eichenlaub, Washington, D. C.: Some of the rectal anesthetics are very satisfactory to use for some of the operations about the mouth, particularly carcinoma of the tongue. They displace chloroform and ether and gas, which does not give relaxation, and good work can be done with such an anesthetic.

Dr. Walter J. Highman, New York: I hope that dermatologists will become the kind of surgeons Drs. MacKee and Stone pointed out, but I should hate to see surgeons become dermatologists. Surgery of the skin began modestly in the boudoir with a lady, an acne pustule and a needle. Today dermatology is largely a matter of relieving skin disturbances by any methods we can master. One of the methods is minor surgery in all its ramifications, including elaborate machinery and modest escharotics in the chemical group. Obviously, it is necessary to master this type of therapy, just as much as I believe a chauffeur should understand the method of getting his car going on the road when there is no sign of a service station. I agree with the authors that the dermatologist of the future should be as capable a surgeon as he must be a chemist and a pathologist. In spite of my fulmination against the mechanistic era I still concede that machinery has virtue, as much as endocrinology, for example, and I wish enthusiastically to endorse what Drs. MacKee and Stone pointed out, that the time is over when a fountain pen, a prescription pad and Latin terminology are sufficient for the entire dermatologic approach to patients suffering from skin diseases. I am entirely in accord with the surgical point of view that has been advocated by the authors.

Dr. George M. MacKee, New York: I agree with Dr. Wise as to the advisability of a consultation before treating melanoma, but only because of medicolegal protection—division of responsibility—as in many other diseases and branches of medicine. I think that the dermatologist should be, and eventually will be, just as capable, if not more so, of removing a melanoma by scalpel surgery or surgical diathermy as is the general surgeon. A great deal is heard about the necessity for enormously extensive excisions in the case of malignant and potentially dangerous lesions. I have seen lesions the size of split peas removed by excising an area the size of an adult hand. Accurate judgment is called for here—judgment based on a knowledge of cutaneous pathology, clinical dermatology and the principles of surgery. Of perhaps greater importance is the depth of the excision. The pathologic cells often, even in a clinically superficial lesion, extend downward and outward along nerves and vessels to the muscle; therefore, the excised tissue should be roughly triangular, with the blunt apex of the triangle upward. Another reason why we believe that adequately trained dermatologists are better able to handle the many dermatosurgical conditions is illustrated by keloid and hypertrophic scars. Few surgeons know how to treat these conditions. Most surgeons believe that hypertrophic scars are due to tension. Many of them are due to this cause and some of them will disappear spontaneously regardless of the cause. However, many hypertrophic scars will not improve without proper treatment. Such lesions can be greatly improved and keloids can be prevented by using radium or the roentgen ray at the proper time. Very thick keloids often cannot be eliminated with an amount of radiation that can be judiciously administered. The properly trained dermatologist will excise the lesion with scalpel surgery if it is of suitable size and location. If the lesion is extensive and thick, he will pare it down with a scalpel or with surgical diathermy. Finally, he will employ radium or the roentgen ray at the proper time and in the proper manner to avoid recurrence. It should be emphasized that those not surgically trained should not attempt scalpel surgery. I predict that in the future most if not all surgery that can be called dermatosurgery will be performed by dermatologists.

ROENTGENOLOGY OF THE UPPER RESPIRATORY TRACT

WITH ESPECIAL REFERENCE TO THE LARYNX AND ADJACENT STRUCTURES *

HENRY K. PANCOAST, M.D.
PHILADELPHIA

The upper respiratory tract, from the nasopharynx to the carina, has recently become a very important field for roentgenologic diagnosis. The most important factor in diagnosis is a careful study of the soft structures during an examination of the neck. This includes fluoroscopic observations of the movements or changes in lumen of the various portions of the tract during respiration, speech and swallowing, and the making of roentgenograms for records. In all instances the chest should be included, and especially in infants and young children.

It seems strange that, following Scheier's studies of speech mechanism in 1909[1] and of the swallowing act in 1911,[2] the publication of Thost's beautiful atlas[3] recording his observations on the normal and pathologic larynx in 1913 and Iglauer's[4] pioneer work in this country in 1914, the subject of diagnosis of diseases of the upper respiratory tract by roentgen methods should have lain almost dormant for several years, at least in America. Sporadic articles have appeared more recently on different phases of roentgenology of the upper respiratory tract or the neck, as by Pfahler[5] on the thyroid, Iglauer and Ransohoff[6] and Tucker[7] on retropharyngeal abscess, Manges[8] on nonopaque foreign bodies in the trachea, Barclay[9] on phonation, and more recently by Hickey[10] and Brown and Reineke[11] on the general examination of the cervical portion of the respiratory tract. The first collective studies of the entire upper air passages and the soft tissues of the neck seem to have been made by Hay[12] from the normal and pathologic material in our department. Since the beginning of Hay's work, the members of our staff have realized that the only way of determining accurately the potential dangers of the thymus in infancy is through a study of its effects on the upper respiratory tract and not by an estimation of its dimensions.[13]

In all examinations of the neck, fluoroscopy is the first procedure. The eyes should be accommodated first until it is possible to see the ventricles of the larynx. After a general survey of the region with the head in the midposition, the patient is directed to pronounce certain vowel sounds, and the changes in the appearance of the ventricles are noted. The air-containing, zeppelin-shaped cavity of the ventricles should be shown clearly if the larynx is normal. Seeing it without deformity practically excludes any severe inflammatory condition in the larynx and any growth in the region of the cords. If it is not visible, one is justified in assuming the presence of a growth, inflammatory process or paralysis of the vocal cord.

The next observation should be made of the arytenoid cartilages, which move with speech and change their relations with swallowing. They are seen easily in the normal subject because they are well surrounded by air. Being under control of practically the entire musculature of the larynx, and subject to lateral and sagittal movements, they will vary considerably in appearance and position in roentgenograms; hence fluoroscopic observations of their movability and configuration are necessary in the final interpretation. They may appear thick or thin and clean cut under different circumstances.

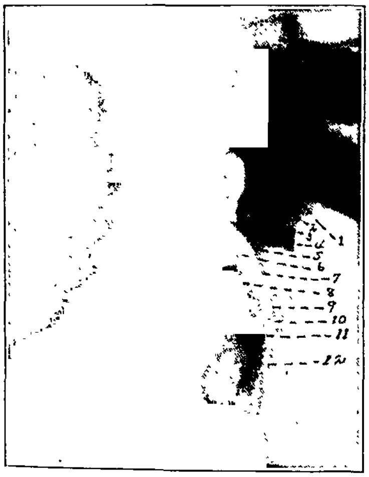

Fig. 1.—Normal neck of a woman, aged 29: 1, soft palate and uvula; 2, posterior border of tongue and pharynx; 3, epiglottic vallecula; 4, hyoid bone; 5, epiglottis; 6, aryepiglottic folds, with pyriform sinuses behind and below; 7, vestibule of the larynx; 8, arytenoids; 9, ventricular bands; 10, ventricles; 11, vocal cords, partly overshadowed by the cricoid; 12, trachea.

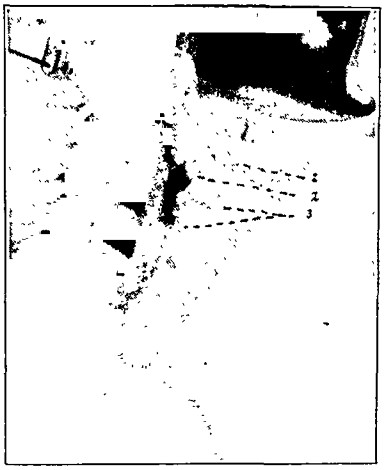

of a woman, aged ossification of the thyroid cartilage; [illegible] articulation of one with the cricoid; 3, cricoid, wide posteriorly, and partly covered by lower border and lower cornu of thyroid.

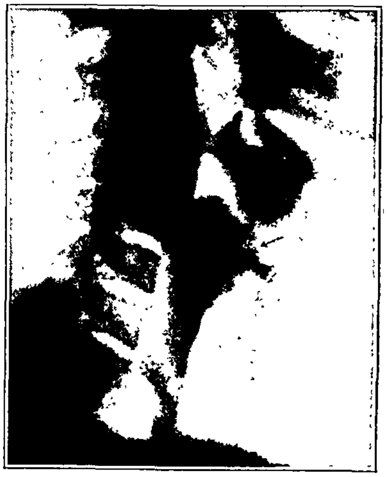

Fig. 3.—Early carcinoma of vocal cord, junction of anterior and middle third, projecting upward into the ventricular space. (Could be seen by fluoroscope.) The outlines of the ventricles are hazy. Confirmed by endoscopy and removed. Biopsy, early carcinoma. Chief complaint, hoarseness for eight months. (Referred by Dr. Tucker.)

The lumens of the pharynx, pyriform sinuses, vestibule of the larynx and the trachea should be carefully noted. All of the structures so far mentioned are seen easily if the eyes are properly accommodated. They are always recorded in the final roentgenogram (fig. 1).

The next procedure is a study of the swallowing mechanism, for the determination of the integrity of the motor mechanism of the pharynx, larynx and upper esophagus; the movability of the epiglottis, arytenoids and the entire larynx; the outlining of growths on the tongue, in and around the epiglottis, the pyriform sinuses and the upper esophagus, and, finally, the patulousness of the food passage. Before studying the swallowing act, one should note particularly the relations between the arytenoids and the epiglottis, the position of the latter and the level of the larynx. Ossification is a great aid in making the larynx visible, and in persons as young as 17 or 18 years, the beginning centers in the posterior ring of the cricoid may be seen.

On the basis of the observations of my colleagues and myself we have divided the swallowing act into five stages, as follows:

1. Preparation for the act. The mouth is seen filled with the opaque liquid mixture. The base of the tongue moves back toward the postpharyngeal wall.

2. As the opaque mixture begins to enter the pharynx, the base of the tongue moves back farther and pushes the epiglottis back slightly. Coincidentally, the larynx rises and the arytenoids come in contact with the under surface of the edge of the epiglottis. We have concluded that the tongue and not the food bolus causes the slight backward tilt of the epiglottis.

3. The peak of the act. As the pharynx becomes filled, the oropharynx is completely obliterated, the larynx is elevated still farther and the arytenoids and epiglottis cannot be differentiated. The hyoid bone is considerably raised.

4. The food has passed into the esophagus and the pharynx and pyriform sinuses are empty. The larynx has descended slightly and the arytenoids have separated from the epiglottis, which has raised to its normal position. The hyoid bone has descended.

5. The swallowing act is completed and all of the structures have returned to their normal relations.

We have observed the foregoing phenomena fluoroscopically and have been able to record the stages by roentgenograms. The opaque mixture used has been a thin suspension of bismuth, just thick enough to cast a perceptible shadow and not to obscure the various structures that should be studied. The soft, pliable wafer employed by Scheier[2] has not been tried, but its use is contemplated in order to observe any possible differences in details of the mechanism that may depend on boluses of different consistencies. Sometimes it is advantageous to use a bismuth capsule in order to study abnormalities of the swallowing act.

After the fluoroscopic study has been completed, a lateral roentgenogram of the neck is made, and the exposure is timed to occur during phonation of a vowel sound. I had always used the vowel E until Dr.

Hickey[14] convinced me that the ventricles could be shown to better advantage during the phonation of A. If any abnormalities of the swallowing act or any evidences of an extrinsic lesion or an advanced intrinsic laryngeal lesion have been noted or suspected fluoroscopically, another lateral roentgenogram is made after the swallowing of a small amount of opaque liquid or a bismuth capsule, according to the special indications. The roentgenograms are interpreted in conjunction with the recorded fluoroscopic observations.

After one has become thoroughly familiar with normal fluoroscopic and roentgenographic appearances it is possible to apply this knowledge to the detection of a large number of pathologic conditions involving the upper respiratory tract, the esophagus and the soft tissues of the neck. There are so many conditions that can be detected that this presentation must be limited to the larynx.

THE NORMAL LARYNX

In the roentgenograms of the normal neck (fig. 1) the following structures should be recognized readily: the soft palate, posterior border of the tongue, epiglottis and vallecula, pharynx, pyriform sinuses and the retropharyngeal, retrolaryngeal and retrotracheal soft tissue spaces. In connection with the larynx directly, one should see the vestibule, arytenoids, aryepiglottic folds, ventricular bands and the ventricles. All paired structures are superimposed. The upper border of the shadow of the vocal cords should be visible, but their lower portions are usually obscured by the cricoid cartilage. The thyroid and cricoid cartilages often can be differentiated without ossification, but its presence aids considerably. Ossification was first studied extensively by roentgenographic means by Fraenkel,[15] in 1908. It is readily shown at the earliest stages and there is no reason why present textbook anatomic knowledge of this subject should not be checked up by extensive roentgen examinations of a large number of living subjects. The trachea is always easily seen.

Tumors of the Larynx.—There are five appearances by which laryngeal neoplasms may be recognized. These may be summarized as follows:

1. Direct evidence of a localized nodule encroaching on the air space of the vestibule, ventricles or subglottic region (figs. 3 and 4). Benign tumors are usually clean cut in outline and distinctly localized, whereas malignant growths are hazy and fade off gradually into the surrounding structures, which also are hazy, as the result of infiltration, edema or inflammatory reaction.

2. Obliteration of the ventricles. Inability to demonstrate the ventricles implies either a growth, inflammatory condition or paralysis of a vocal cord and calls for a laryngoscopic examination (fig. 5).

3. Irregularity, haziness or change in direction of the normally clean cut horizontal line at the lower border of the larynx (figs. 1 and 5). A change in the direction of the line must not be confused with the slant of a visible lower border of the cricoid cartilage.

4. Complex changes in appearance due to extensive growths. These may be various encroachments on the air spaces, thickening of structures, defects due to destruction of tissue, distortions and displacements (figure 6).

5. Infiltration of cartilage. This cannot be determined unless there is extensive ossification, which, however, is usually irregular and deceptive. One is never justified in interpreting erosion unless the adjacent soft tissues are swollen and hazy. We have rarely felt justified in interpreting it.

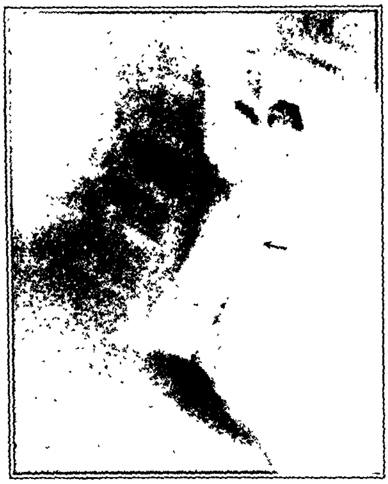

Fig. 4.—Pedunculated benign tumor of vocal cord, encroaching on the lumen of the trachea. Confirmed by endoscopy and removed. Biopsy, benign tumor. Chief complaint, hoarseness for two years. (Referred by Dr. Jackson.)

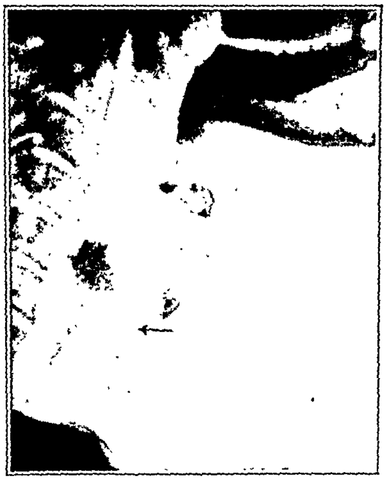

Fig. 5.—Carcinoma of vocal cord. Encroachment on air space below the larynx and absence of ventricles. Endoscopy, extensive infiltration and ulceration involving right cord. Biopsy, squamous carcinoma. Hoarseness one year, weight loss and recent dyspnea. (Referred by Dr. Jackson.)

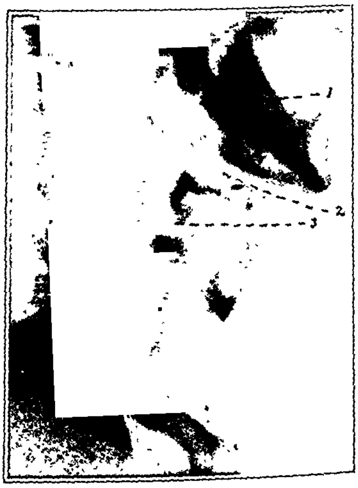

Fig. 6.—Extensive carcinoma involving the soft palate, 1; base of tongue, vallecula and epiglottis, 2; postpharyngeal wall on one side, pyriform sinus, 3; arytenoids, extending down farther into larynx, with obliteration of ventricles. This diagnosis was made before the extent of the lesion was known clinically. Biopsy, squamous carcinoma. Patient consulted physician because of swelling in neck. (Referred by Dr. Muller.)

Paralysis of the Vocal Cords.—In every case with paralysis of the vocal cord examined in our clinic with a view of making a diagnosis of a laryngeal condition there has been observed some deviation from the normal in the appearance of the ventricles (fig. 7). The following different appearances have been noted:

1. Half zeppelin shape, the lower half being obliterated. A similar appearance is sometimes noted in normal individuals in whom the cricoid is dense, but the half space is wider than in paralysis of the cord.

[15] Fraenkel, E.: Ueber die Verknöckerung des menslichen Kehlkoffs, Fortschr. a. d. Geb. d. Röntgenstrahlen 12: 152-168, 1908.

2. The zeppelin shape can be made out, but the posterior half of the space is closed on one side by a contraction upward of the lower part of the posterior portion. In both of these types the borders of the space are clean cut, and not hazy as when the deformity is due to growth.

3. Complete obliteration of the space. In such cases the appearance cannot be distinguished from an inflammatory condition or a growth.

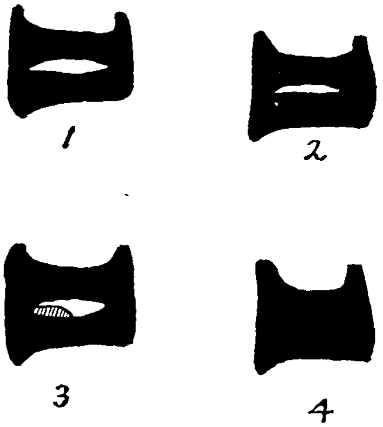

Fig. 7.—Various appearances of the ventricles in vocal cord paralysis: 1, the zeppelin shaped normal ventricles; 2, the half zeppelin shape noted in some cases; 3, contraction of the lower part of the posterior portion on one side; 4, complete obliteration.

Cases of bulbar paralysis present interesting phenomena which will usually lead one to suspect the condition after a study of the movements of phonation and swallowing. There is not found any local evidence of disease or neoplasm, so that the diagnosis is to be made by exclusion. In connection with paralysis of the cord, it has not been possible to identify any of the appearances found with any particular form of involvement of the nerves. The arytenoids do not seem to show any characteristic appearance, location or disturbance in movements.

Inflammatory Conditions.—These include acute laryngitis, streptococcic laryngitis, acute laryngeal diphtheria, postdiphtheritic stenosis, posttyphoidal perichondritis, syphilis and tuberculosis.

In severe acute laryngitis, the outlines of the air spaces are hazy and the ventricles may be obliterated.

In one case of streptococcic laryngitis there was obliteration of the ventricles, haziness of the arytenoids and a general blurring of the outlines of the vestibule.

A single case of acute laryngeal diphtheria showed swollen arytenoids, retrolaryngeal swelling, obliteration of the ventricles and narrowing of the upper end of the trachea. The differentiation between the three conditions just mentioned is not clean cut, and the best one can do in children is to render a diagnosis of an inflammatory condition requiring direct laryngoscopy.

The presence and extent of postdiphtheritic stenosis is always well demonstrated by fluoroscopy and roentgenograms. There is obliteration of the ventricles and narrowing of the vestibule of the larynx. The characteristic feature is the narrowing or complete obliteration of the lumen of the upper trachea, which becomes either the shape of an inverted funnel, narrowed down almost to a point or entirely shut off for some distance below the larynx. The loose tissue in the conus elasticus from the cords to the first tracheal ring is the seat of the most intense inflammatory reaction and subsequent contraction, and there may be a perichondritis of the cricoid; hence the seat and appearance of the stenosis (fig. 8).

In one case of posttyphoidal stenosis of the larynx there was an absence of the ventricles and disturbed motility of the arytenoids with general blurring of the outlines. Endoscopy showed perichondritis of the larynx and fixation of the left arytenoid. This case did not have the typical appearance of the upper trachea seen in postdiphtheritic stenosis, and there was nothing really characteristic of the condition.

In the many cases of tuberculous and syphilitic laryngitis studied nothing was found that could be regarded as characteristic of the disease or differing from the appearances of many malignant growths. Roentgenologic evidence of pulmonary tuberculosis will have an important bearing on the diagnosis.

SPEECH MECHANISM FOLLOWING LARYNGECTOMY

Through the courtesy of Dr. Fielding O. Lewis, the speech mechanism of two cases following some time after laryngectomy for carcinoma was studied in our clinic. The following mechanism in the first patient was observed fluoroscopically and recorded roentgenographically, as previously reported in detail:[12]

First stage, filling of the pharyngeo-esophageal reservoir with air.

Second stage, fixation of the muscles of the pharynx and upper esophagus. The cricopharyngeus appeared as a distinct band at the lower end of the space and separated the upper cavity from the esophagus.

Third stage, firm contraction of the cricopharyngeus at the beginning of speech, which consisted in counting from one to eight, and a decrease in size of the reservoir.

Fourth stage, complete collapse of the reservoir at the count of eight and exhaustion of all available air.

The second case presented essentially similar phenomena, although the procedure differed somewhat in minor details. He did not fill the reservoir so full of air, but could keep up a continuous supply and was able to talk continuously by taking air in through his nose. He did not, therefore, present the definite stages of the first case. There were, in addition, certain psychologic elements in the technic of more importance to the individual than of scientific interest or, perhaps, of necessity.

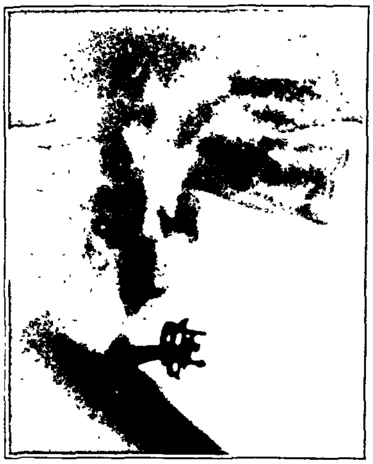

Fig. 8.—Complete postdiphtheritic stenosis of larynx and upper trachea.

CONCLUSIONS

The portion of the upper respiratory tract in the neck has been a neglected field for roentgenologic study.

Practically all of the pathologic conditions presented by the larynx and neuromuscular disturbances show some recognizable phenomena or abnormal appearances, many of which are characteristic.

The examination must be both fluoroscopic, for studying moving parts, and roentgenographic, for purposes of record and finer details.

The study of phonation and the swallowing act is essential in all cases. Both of these functions are described.

3400 Spruce Street.

THE DIAGNOSIS OF LARYNGEAL DISEASE

LARYNGOSCOPIC APPEARANCES CORRELATED WITH ROENTGENOLOGIC OBSERVATIONS *

CHEVALIER LAWRENCE JACKSON, M.D.
PHILADELPHIA

Hoarseness, the most common symptom of laryngeal disease, always calls for careful diagnostic study. Too often patients with this complaint are sent away with a casual diagnosis of "laryngitis." As a result, the patient with early and easily operable cancer, or incipient tuberculosis, is allowed to go on for months without an accurate diagnosis and appropriate treatment.

The complaint of hoarseness calls for the following diagnostic studies:

1. A complete history.
2. Mirror laryngoscopy.
3. Roentgenographic study of the neck and chest, and in most cases also of the sinuses.
4. Complete general physical examination with particular attention to the chest.
5. Blood Wassermann test.
6. Sputum analysis.
7. Direct laryngoscopy (if indicated).
8. Biopsy (if indicated).

After the taking of the history, the first step in the diagnosis of laryngeal disease is to look at the larynx. This can be accomplished by the indirect method in almost all adults and older children. If the mirror view is satisfactory, it may or may not be necessary to do a direct laryngoscopy in addition. A satisfactory mirror view will usually justify a tentative diagnosis. Laryngoscopic appearances may be quite characteristic in such conditions as cancer, tuberculosis, benign neoplasms, vocal nodules, or recurrent paralysis. In almost all cases, however, this diagnosis must be regarded as only a tentative one, and further studies carried out.

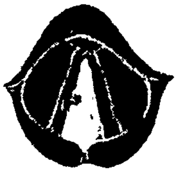

Fig. 1 (case 1).—Small growth on right vocal cord.

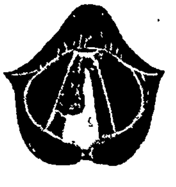

Fig. 2 (case 2).—Growth attached to anterior half of right cord.

Of these, one of the most helpful is the roentgenographic examination. The roentgen ray has for a long time been of the greatest help in laryngeal diagnosis, by showing the presence or absence of tuberculous disease in the chest, and, in cases of laryngeal paralysis, by showing an aneurysm, subternal goiter, mediastinal neoplasm, or other lesion involving or pressing on the recurrent laryngeal nerve. The recent work of Pancoast and Pendergrass has developed the roentgenology of the neck to such a degree that the fluoroscopic and roentgenographic study of the larynx itself is of the greatest importance in diagnosis.

REPORT OF CASES

The cases discussed in this paper were selected from a series studied in consultation with Dr. Pancoast. The laryngoscopic appearances illustrated are those seen on indirect examination. In a number of the cases direct laryngoscopies were subsequently done, for biopsy or for treatment. I am indebted to Dr. Gabriel Tucker for access to some of the clinical material.

BENIGN NEOPLASMS

Case 1.—D. P., a woman, aged 32, complained of hoarseness of two months' duration. Mirror laryngoscopy showed a small growth on the right vocal cord. Roentgenographic examination showed the shape of the ventricle of the larynx to be abnormal, "suggesting a monolateral laryngeal lesion." The blood Wassermann reaction was negative. Direct laryngoscopy was done for the removal of the growth, which on histologic examination was proved to be benign in character.

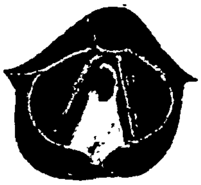

Fig. 3 (case 3). — Irregular growth in anterior commissure, attached to right cord.

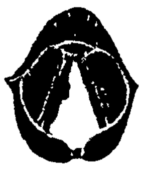

Fig. 4 (case 4).—Irregularity of surfaces of right cord, with mass attached to free margin of right cord at junction of anterior and middle thirds.

Case 2.—W. M., a man, aged 36, complained of hoarseness of ten years' duration. Mirror examination showed a growth attached to the anterior half of the right cord. Roentgenographic study showed obliteration of the ventricle. The blood Wassermann reaction was negative. This growth was removed by direct laryngoscopy and microscopic examination showed it to be a soft fibroma.

Case 3.—C. S., a woman, aged 27, complained of hoarseness of about eight months' duration, and some loss of weight. Mirror laryngoscopy showed an irregular pinkish growth in the anterior commissure, apparently attached to the right cord. The growth was removed by direct laryngoscopy, and the pathologist reported it to be an angiomatous polyp.

Case 4.—K. C., a man, aged 62, dated symptoms from a "heavy cold," eight months before. There was a previous diagnosis of papilloma, and several unsuccessful efforts had been made to remove it. Mirror laryngoscopy showed considerable irregularity of the surfaces of the right cord. An irregular mass the size of a coffee-bean was attached to the free margin of the right cord at the junction of its anterior and middle thirds. Roentgenographic examination of the larynx showed a small growth on the vocal cord at the junction of its anterior and middle thirds, as indicated by encroachment of a mass of soft tissue on the lumen of the ventricle. General physical examination by Dr. Kern showed nothing abnormal except for slight generalized adenopathy. The blood Wassermann reaction was negative. Direct laryngoscopy was done and a specimen taken for histologic examination. There was some suspicion of early malignant changes, and the patient was asked to return in one month. He did so and another specimen was taken, which showed only inflammatory reaction. The appearance of the lesion had greatly improved. The patient was instructed to keep his larynx under the close observation of his physician and to avoid all forms of vocal abuse.

CANCER

Case 5.—C. G., a man, aged 41, dated hoarseness back about one year. There was a complaint also of "dull pain in the throat." The patient thought his trouble followed a "cold." Huskiness of voice persisted in spite of medication. Mirror examination showed a small irregular tumor mass just under

---

* Read before the Section on Laryngology, Otology and Rhinology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

the edge of the left vocal cord. Roentgenographic study of the neck showed an inflammatory or neoplastic process in the region of the larynx. The ventricles of the larynx were not visible. The diagnosis of cancer was subsequently confirmed by biopsy, and a laryngofissure performed.

CASE 6.—M. H., a man, aged 64, complained of hoarseness for the past two months and a slight feeling of soreness in the throat. Mirror examination showed a lesion involving the entire left cord. It was rather pale and showed an irregular ulcerated surface. The motility of the left cord seemed slightly impaired. Roentgenographic study of the neck showed absence of the ventricle, suggesting infiltration from a growth in that region. On physical examination, Dr. Perry Pepper found the patient in excellent general condition. The blood Wasserman reaction was negative. Direct laryngoscopy showed the lesion to extend well back to the posterior commissure, and slightly subglottic. A specimen was removed for biopsy, and the pathologist's report was squamous epithelioma. Laryngectomy was performed, as the lesion was too extensive for laryngofissure.

CASE 7.—E. E., a man, aged 45, complained of hoarseness of three years' duration. Operation had been advised a number of times, but the patient had refused. He now became alarmingly short of breath. Mirror examination showed a large irregular mass beneath the epiglottis, extending entirely across its base and overhanging the glottis. The mucosa covering the mass was ulcerated and bleeding. There was no impairment of the motility of the arytenoids. Palpation of the neck showed the contour of the larynx to be irregular, and there was a soft bulging over the cricothyroid membrane. Roentgenography of the neck showed swelling of the soft tissues in front of the thyroid cartilage. There was obliteration of the ventricle, and an irregularity in the density of the thyroid cartilage, suggesting infiltration from a growth or inflammatory process. The blood Wassermann reaction was negative. Direct laryngoscopy was done and ample specimens were removed for biopsy. The pathologist reported squamous epithelioma.

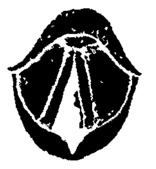

Fig. 5 (case 5).—Small tumor mass just under edge of left vocal cord.

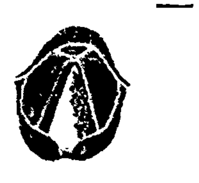

Fig. 6 (case 6).—Lesion involving entire left cord.

TUBERCULOSIS

CASE 8.—J. R., a man, aged 51, complained of difficulty in swallowing, and pain in the throat. Mirror laryngoscopy showed an ulcerative lesion on the internal surface of the tip of the left arytenoid, about half the size of the little finger nail, with an infiltrative base. The surface was pale and granular. Roentgenographic examination of the chest showed extensive infiltration, with some cavitation in both upper lobes. The trachea was retracted to the right. Roentgenographic study of the neck showed abnormality in the region of the larynx also, and a diagnosis of pulmonary and laryngeal tuberculosis was made. The blood Wassermann reaction was negative. In the absence of positive sputum it was thought advisable to remove a specimen for biopsy. This was done by direct laryngoscopy, and the pathologist reported chronic inflammatory tissue with tubercles containing giant cells, though special staining of the tissue for tubercle bacilli gave negative results.

CASE 9.—J. M., a man, aged 33, developed pulmonary tuberculosis, with positive sputum, about two years before I first saw him. He had had hoarseness for about ten months. Mirror laryngoscopy showed an ulcerative lesion involving the posterior commissure and extending forward on both cords, for approximately their posterior thirds. There seemed to be no impairment of motion of the arytenoids. The local appearances had the characteristics of a tuberculous lesion. Roentgenographic examination showed an infiltrative inflammatory process in the region of the larynx, and a diffuse infiltration through both lungs, especially the upper lobes. The diagnosis was pulmonary tuberculosis with secondary involvement of the larynx.

SYPHILIS

CASE 10.—B. C., a woman, aged 44, was severely dyspneic when admitted to the hospital. This attack was only of two days' duration, but there had been previous attacks. Mirror laryngoscopy showed the left cord to be almost motionless, and in the subglottic region, just below the left cord, there was a red swelling. The airway was markedly reduced. Roentgenography showed a definite narrowing of the airway just below the ventricle of the larynx, as well as increased width of the upper portion of the post-tracheal space. The blood Wassermann reaction was strongly positive and the diagnosis was syphilitic perichondritis. Tracheotomy was performed for the relief of dyspnea and antisyphilitic treatment begun. The patient was subsequently decannulated.

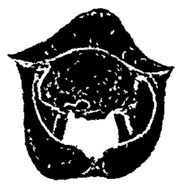

Fig. 7 (case 7).—Mass beneath epiglottis, overhanging the glottis.

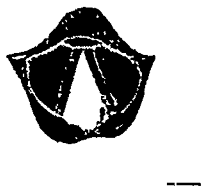

Fig. 8 (case 8).—Lesion on internal surface of tip of left arytenoid.

PARALYSES

CASE 11.—A. G., a man, aged 57, had been annoyed for fifteen months by a sensation of "lump in the throat." The onset was very vague. At times he had pain on swallowing. Mirror laryngoscopy when the patient was first seen was negative. On fluoroscopic study, slight hesitation of the opaque capsule was noted at the level of the suprasternal notch. Physical examination by Dr. George M. Piersol showed the patient to be in quite good general condition. The blood Wassermann reaction was negative. Mirror examination a short time later showed posticus (abductor) paralysis of the right vocal cord (fig. 11 *A*), and direct examination of the hypopharynx and esophagus was advised. At direct examination the larynx was lifted forward with an adolescent laryngoscope, and an ulcerating, fungating mass was found on the posterior esophageal wall, just back of the cricoid cartilage. A specimen of tissue was removed for microscopic examination and the pathologist reported squamous epithelioma. Roentgenography showed an increased retrotracheal space. The patient finally developed a bilateral cord paralysis, requiring tracheotomy. The drawing (fig. 11 *B*) shows that the right cord has become cadaveric, while a posticus (abductor) paralysis of the left cord has developed in addition. (Both *A* and *B* show the glottis on full inspiration.)

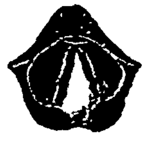

Fig. 9. (case 9).—Lesion involving posterior commissure and extending forward on both cords.

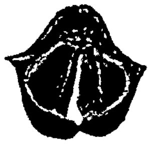

Fig. 10 (case 10).—Left cord almost motionless; in subglottic region, just below the left cord, a red swelling.

Case 12.—M. R., a man, aged 59, had been having some difficulty in swallowing solids for about six months and had lost some weight. Mirror laryngoscopy at this time was negative, and no abnormality was found on palpation of the neck, except tenderness on pressure over the trachea just below the cricoid cartilage. Fluoroscopic study showed lodgment of the opaque capsule just below the level of the suprasternal notch, and the capsule was not dislodged until after many swallows of water. The thick paste was moderately obstructed in passing the suprasternal notch, but the liquid mixture passed readily. There was slight dilatation of the esophagus above the obstruction. There was also distinct retrotracheal swelling, and a moderate compression stenosis of the trachea at the level of the suprasternal notch. There was an "eccentric constricted channeling of the esophagus" for a distance of 6 cm. in its upper third. On esophagoscopy a bleeding mass was found obstructing the lumen of the esophagus just below the cricopharyngeal pinchcock. A specimen of tissue was removed, and the pathologist confirmed the diagnosis of squamous carcinoma.

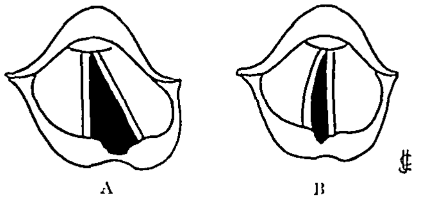

Fig. 11 (case 11).—Glottis on full inspiration: *A*, posticus (abductor) paralysis of right vocal cord; *B*, right cord cadaveric, with posticus (abductor) paralysis of left cord.

The patient was discharged, high voltage roentgen therapy being advised. The patient did not have this carried out, but two months later he returned with a left recurrent paralysis, and increased difficulty in swallowing.

Case 13.—J. C., a man, aged 61, complained chiefly of dysphagia of about one year's duration, but he complained also of strangling attacks and difficulties of speech. The family physician had suggested the diagnoses of small aneurysm of the descending aorta, thyroid neoplasm, or mediastinal growth. Mirror laryngoscopy showed marked impairment of motion of the left cord, which seemed slightly crescentic. The right cord was also somewhat sluggish, and its movements seemed incoordinate. Roentgenography showed slight dilatation of the aortic arch. A blurring of the ventricles of the larynx was noted of such character as would be explained by a paralysis of the vocal cords. The blood Wassermann reaction was negative. Neurologic examination by Dr. Spiller led to a diagnosis of progressive spinal muscular atrophy developing into bulbar palsy. Esophagoscopy showed no organic lesion in the esophagus and no esophageal compression.

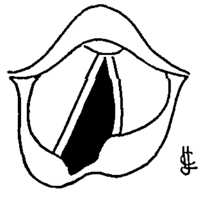

Fig. 12.—Left recurrent paralysis (glottis shown on full inspiration).

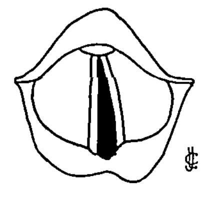

Fig. 13 (case 13). — Impairment of motion of left cord; right cord sluggish, its movements seeming incoordinate.

CONCLUSION

This series of cases demonstrates the value of fluoroscopic and roentgenographic study of the neck in the diagnosis of laryngeal lesions. The roentgenologist can now detect inflammatory and neoplastic processes in their incipience, when they are causing only the mildest symptoms.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. PANCOAST AND JACKSON

Dr. Samuel Iglauer, Cincinnati: I think Drs. Pancoast and Jackson are to be congratulated on the thoroughness with which they investigated the subject, and especially on the fluoroscopic studies. Dr. Pancoast has brought out not only the anatomy of some of the lesions but also the physiology of these parts. The question of ossification in the larynx is important because the roentgenologist who is not familiar with the subject will often state that there is a foreign body behind the larynx when what is really shown is ossification of the cartilage. According to the studies of Scheier, ossification follows a definite course. Ossification first appears in the thyroid cartilage at the age of 18; later the cricoid begins to ossify; the tracheal cartilages are the last to ossify. A study of ossification is also important if one is going to perform laryngofissure, since one knows in advance whether one is going to cut through bone. The x-rays are of value in studying laryngotracheal stenosis, usually revealing a narrowed air column in the obstructed portion of the larynx or upper part of the trachea. The narrowing of the lumen can sometimes be delineated to better advantage by the injection of iodized oil into the larynx. When the patient wears a tracheal cannula, the stenosis may also be demonstrated by pulling a rubber sausage containing an opaque medium into the larynx above the cannula. The x-rays are of value also in showing the position of intubation tubes or permanent rubber dilators introduced for treatment and also in the instruction of students in the use of intralaryngeal instrumentation. In a case of congenital laryngocele I was able to demonstrate the distended air sac in the neck when the patient made forced expiratory efforts. Swellings encroaching on the lumen of the larynx or trachea, such as retropharyngeal abscess, are readily demonstrated by the x-rays and are of considerable importance in the diagnosis and control of treatment of these conditions. A sign of great value in perforation of the esophagus or pharynx is the presence of clear spaces in the swollen area. These air bubbles can often be demonstrated by the x-rays without the presence of any palpable emphysematous crackling at the root of the neck. While it may be impossible to diagnosticate by x-rays a particular disease such as tuberculosis of the larynx, nevertheless the x-ray film will usually show more involvement of the underlying perichondrium and cartilage than one would expect from the ordinary laryngeal examination.

Dr. William V. Mullin, Cleveland: The cases that are most troublesome to me are those in which I am unable to arrive at a correct diagnosis at the first examination. Many patients come from a distance and sometimes fail to return for subsequent study, so that a prompt diagnosis is urgently needed. At one time I believed that laryngeal tuberculosis could be diagnosed by the x-rays. Dr. Pancoast says that it is not possible to demonstrate this condition roentgenographically, and doubtless he is correct. In an army hospital for tuberculosis we had roentgenograms made in several hundred cases. Our idea at that time was that tuberculous infiltration starts at the bottom of the laryngeal tissue next to the cartilage and travels to the surface, and we believed we could see these densities and infiltrations coming to the surface. We were not able, however, to confirm our observations by postmortem or pathologic examinations. Dr. Pancoast says that chondritis cannot be demonstrated by x-rays, which explains the results in a recent case. A boy, aged 16 years, was very hoarse and had a discharging fistula in front of the thyroid cartilage. Two months previously, two teeth on the left side had been extracted under local anesthesia. After this, sore throat developed and then apparently a peritonsillar abscess on the left. The abscess was incised, and a swelling appeared in the neck in front of the thyroid cartilage. This also was incised, to be followed by a lung abscess which evidently evacuated spontaneously. At the time I saw the patient the appearance of his larynx was almost that of tuberculosis, both false cords being infiltrated to such an extent that they made an approximation before the true cords, producing the hoarseness. Examinations by smear and guinea-pig inoculation were negative for tuberculosis. Complete roentgen study of the larynx showed nothing; yet at operation complete necrosis of the thyroid cartilage on the right side was found, necessitating the removal of almost the entire right wing. It would seem that such a condition should be evident roentgenographically, but it was not demonstrable in this case.

Dr. Eugene P. Pendergrass, Philadelphia: The fluoroscopic and roentgenographic study of the neck and upper respiratory tract is one of the most valuable supplementary examinations the laryngologists, bronchoscopists and esophagoscopists have at their disposal. The roentgen examination offers a permanent record of the location and extent of the disease or growth, just as the microscopic slide becomes a permanent record of the pathologic process. I do not believe that it is possible for one to say a given case is tuberculosis because of increased calcification of the cartilage, or syphilis because of an associated enchondritis. I do feel, however, that the variation from the normal can be discovered and recorded. The roentgen examination is only a part of the study of the larynx, and it is only after correlation of the laryngoscopic observations, the various laboratory reports, and the roentgen observations that the complete study has been made. The roentgen examination is a most satisfactory method for recording the progress of the treatment of laryngeal and tracheal stenosis. One can see the exact position of any apparatus that is used. Encroachment on the lumen of the larynx and displacement of the trachea from outside pressure are distinctly visible. Such information as this should be of diagnostic importance in assisting one to plan any surgical procedure. The roentgen examination of the neck and upper respiratory tract should be as valuable to the rhinologist and laryngologist as is the sinus examination. Excellent roentgenograms demonstrating soft tissue detail are desirable, but a careful fluoroscopic examination with well accommodated eyes, the observations detailed by Dr. Pancoast being considered, is essential.

Dr. Gabriel Tucker, Philadelphia: It has been my good fortune to be associated with Dr. Pancoast in this work and I consider the roentgenologic aid that he gives invaluable in the diagnosis and treatment of these cases. In laryngeal disease every obtainable aid is necessary in order to make a correct differential diagnosis, for in disease of the larynx early correct diagnosis may mean saving the patient's larynx and, in many instances, his life as well. Mirror examination alone will seldom give sufficient information for a correct opinion. A routine study should be made that includes a careful history, a complete general examination by a competent internist, serologic studies to exclude syphilis, roentgen examination of the neck and chest, and sputum examinations to exclude tuberculosis, as well as repeated mirror examinations of the larynx. Direct examination with the removal of tissue for biopsy is the final step.

Dr. Henry K. Pancoast, Philadelphia: Dr. Iglauer has called attention to the word "cooperation," which is the foundation of the work I have just shown. Without cooperation, roentgenology can create little that is new. The institutions in our part of the country are largely judged by the ability of their roentgenologic departments and the ability of the roentgenologist is largely a measure of the spirit of cooperation in the staff of an institution. Cooperation has been the greatest feature of the work with Dr. Jackson, and more recently with Dr. Tucker, and without that cooperation I would have been absolutely unable to show what I have today. I have had to limit my remarks absolutely to the larynx because if I discussed the entire upper respiratory tract it would take a long time to talk about all the conditions that could be diagnosed. There was an excellent excuse for offering the observations from the roentgenologic standpoint. These cases did not all come from the bronchoscopist. There are many conditions, not only in the larynx but in other portions of the upper respiratory tract, that are never suspected by the clinician, and many of these cases came from clinicians. There is no necessity for any controversy as to whether syphilis and tuberculosis can be diagnosed or differentiated by roentgenologic means. These conditions cannot always be diagnosed or differentiated by direct visualization. The frequency with which cancer exists in conjunction with syphilis is well known. It certainly exists in the mouth and I imagine it does in the larynx, and a biopsy is absolutely necessary. Dr. Tucker has called attention to a case in which tuberculosis and carcinoma exists in the same case, and strange to say microscopically the lesions existed side by side. I think, however, that pulmonary tuberculosis was found in this case at the examination, but biopsy was the final test.

INTERNAL DRAINAGE

ITS APPLICATION IN PULMONARY SUPPURATION *

WILLIAM B. FAULKNER, Jr., M.D.
SAN FRANCISCO

In the study of pulmonary suppuration, intrabronchial drainage [1] has not had the attention that it deserves. This drainage is of two types: "external" and "internal." By external drainage I mean the ability of a bronchus to empty itself by cough and expectoration. Internal drainage, on the other hand, is the inability of a bronchus to empty itself adequately, the pus spilling about from place to place within the lung. This spilling, or internal drainage, is a definite entity in pulmonary suppurations, and an understanding of it is important in the diagnosis and treatment of these conditions.

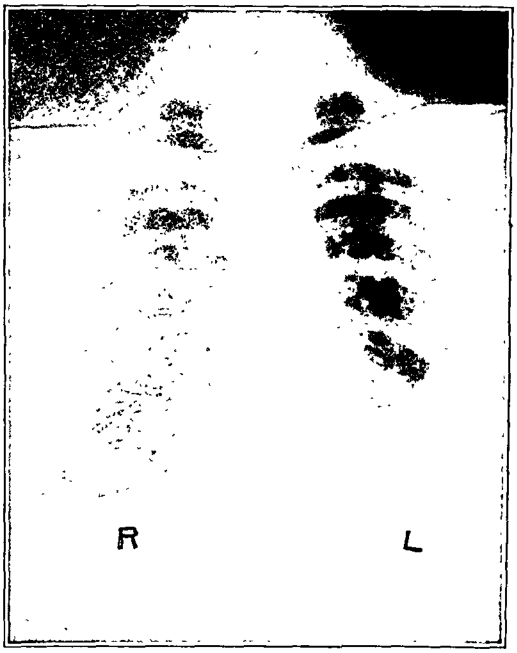

Fig. 1.—Iodized oil injection, illustrating the principle of internal drainage. The oil was introduced through the mouth without any type of anesthesia; consequently the cough reflex was not abolished. The patient was in the erect position during the injection. The oil flowed downward and the bronchi of the right lower lobe were visualized. There is no oil in the remaining portions of either lung. (Iodized oil injection done by Dr. Maurice Lubin.)

The occurrence of internal drainage has been substantiated by iodized oil studies and bronchoscopic examinations. The injection of oil has permitted a study of the accessibility of either lung to intrabronchial secretions from the opposite side and has shown that internal drainage can occur even in the unanesthetized patient in whom the cough reflex has not been abolished. The influence of posture on this drainage is demonstrated in figures 1, 2 and 3.

[1] Brunn, Harold, and Faulkner, W. B., Jr. Intrabronchial Drainage, Its Importance in the Diagnosis and Treatment of Pulmonary Suppurations, Surg. Gynec. Obst. **51**: 115-124 (July) 1930

Bronchoscopic examinations under light ether anesthesia on patients with a left-sided pulmonary abscess have shown pus spilling across from the diseased side into the bronchi of the opposite lung (figs. 4 and 5).

Physical examinations, plain roentgenograms, operative studies, and autopsy observations further support the theory of internal drainage. I have recently seen a patient with a right-sided basal pulmonary abscess in whom practically all the abnormal physical observations were elicited on the left side. On bronchoscopic examination the main bronchi of the left lung were filled with pus. The conception that this intrabronchial secretion must have spilled over from the diseased right side into the left lung while the patient was lying on the left side is supported by the fact that almost all the abnormal physical observations disappeared following bronchoscopic treatment and removal of the pus from the left major bronchi.

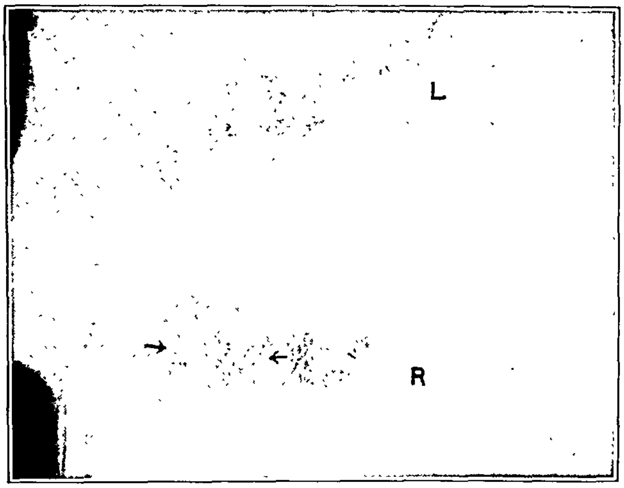

Fig. 2.—Iodized oil injection (internal drainage): Same patient as in figure 1. No further oil was introduced following the taking of figure 1, but the patient had been lying on her right side for fifteen minutes and the iodized oil had spilled from its original position in the lower lobe so as to visualize the right upper lobe bronchi. Note the absence of oil in the left lung. The patient was next turned on her left side. See figure 3.

A second patient, who had been expectorating a pint of pus daily, complained of pain over the right base. Physical examination showed impaired resonance, along with diminished breath sounds and voice sounds, as well as râles over the right lower lobe. The plain roentgenogram showed increased markings at the right base and was interpreted as a possible basal bronchiectasis. The right upper lobe seemed uninvolved on both physical examination and the plain roentgen plates. Iodized oil injection was suggested, and this demonstrated normal bronchi at the base but a very definite enlargement of the bronchi of the upper lobe that had previously appeared normal. Bronchoscopic examination and exploratory thoracotomy confirmed the presence of an upper lobe bronchiectasis. Therefore, the abnormal lower lobe physical observations and x-ray shadows in this case must have resulted from the collections of pus which had spilled by internal drainage from the diseased upper lobe into the lower lobe bronchi (fig. 6).

A young woman who was operated on by means of cautery pneumonectomy for the relief of a right-sided basal pulmonary abscess had an uneventful course for the first few days after operation. She then had a slight hemorrhage from the wound, but this seemed to have been controlled by packing. A few hours later, however, a peculiar air hunger developed and the patient died suddenly. Clinically a pulmonary or cerebral embolus seemed to account for the death. Autopsy disclosed a marble-sized clot of blood in the left main bronchus even though there was no ulceration or abrasion on the left side. Death was, therefore, due to the aspiration, or spilling over, of this clot from the operated right side into the left main bronchus. If I had appreciated the problems of internal drainage at that time, the patient might have been saved by an immediate bronchoscopic treatment and removal of the clot.

In other instances of one-sided pulmonary abscess associated with large amounts of expectoration, similar sudden deaths have occurred shortly after a first-stage pulmonary abscess operation. Postmortem examination in each case showed the bronchi of both lungs completely filled with pus even though the abscess was situated on only one side. This pus must have spilled over from the diseased side into the good lung during and immediately following the operation. Prompt bronchoscopic treatment and removal of the pus would have cleared the passageway and probably would have saved these patients (figs. 7 and 8).

THE MECHANISM OF INTERNAL DRAINAGE

The spilling of intrabronchial secretion is dependent on the following factors: the patency of the bronchial opening; the amount and viscosity of the intrabronchial secretions; the anatomic position of the various bronchial openings; the direction of the bronchial trunks; the site of the primary lung lesion, and the posture of the patient.

If the bronchus is open and the pus is sufficiently thin and in large quantities, the material will spill from the higher to the dependent areas. No spilling will take place if the bronchus is occluded by edema, granulations or thick inspissated pus. Spilling will also be limited in amount when the pus is unusually viscid or in small quantities (fig. 9).

The high position of the right main bronchus, directly opposite the bifurcation, makes this a common site for the collection of secretion when the patient is lying flat on his right side (fig. 10). In this right-sided position, material will spill not only from the right base but also from the left lower lobe into the right upper lobe (fig. 11). The close proximity of the right middle and lower lobe bronchial openings facilitates drainage from one to the other and leaves both liable to spilling from a diseased upper lobe bronchus. This right upper lobe opening is situated about an inch and a half above the middle and lower lobe openings (fig. 12).

Since the middle lobe bronchus runs anteriorly while the lower passes posteriorly, secretions flow from the middle into the lower lobe when the patient is flat on his back, and vice versa when a flat position on the abdomen is assumed (fig. 13). This flow of secretions can be studied by repeated physical examinations. Abnormal physical conditions appear at the areas to which pus spills, and these conditions migrate with changes in posture, as has already been noted in connection with the iodized oil roentgenograms. The areas at which these abnormal signs occur are identical with the sites to which the iodized oil flows, and the physical signs are the same irrespective of whether the intrabronchial secretion is pus or iodized oil.

In the erect position, secretion in the right or left upper lobe migrates to the bases, but material will flow from the right upper across into the left main bronchus when the left side is lowermost (figs. 7 and 8). These observations have been confirmed on numerous occasions. Bronchoscopically, pus has been found in the left lung even when the primary disease was on the right side.

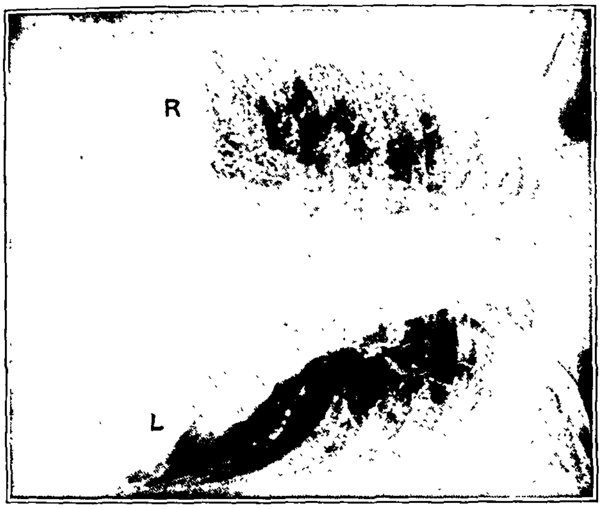

Fig. 3.—Iodized oil injection (internal drainage): Same patient as in figures 1 and 2. No further oil was introduced after figure 1 was taken. The change in the position of the oil resulted from "internal drainage" and was influenced by the posture of the patient. The iodized oil began to spill across into the left lung after the patient lay on her left side. Figures 1, 2 and 3 demonstrate the possibilities for the internal drainage of intrabronchial secretion in the unanesthetized patient in whom the cough reflex has not been abolished. The oil flows to predetermined areas.

By keeping these factors in mind, the possibilities of spilling will be appreciated and postures can be employed to empty the bronchi, or at least to prevent spilling into the opposite lung.

PRACTICAL APPLICATION OF INTERNAL DRAINAGE

Since abnormal physical observations and roentgen shadows appear in the areas to which the pus spills, a diagnosis is to be made only after repeated examinations in various postures. As has been demonstrated, abnormal physical conditions may appear at regions that are quite distant from the source of the trouble, and possibly no clue will be found on either physical examination or a study of the roentgenograms as to the site of the primary lesion. Even bronchoscopic examination may be misleading, because the constant spilling of pus from one area to another will set up transient secondary inflammatory changes at the regions to which the spilling takes place. These secondary changes must not be mistaken for the main source of the trouble. Because of the difficulty of diagnosis, all the available aids should be employed before making a decision as to the site of the abscess.

In view of the dangers of internal drainage, a careful choice of anesthetic is demanded so that the patient will awaken shortly after operation before the pus has spilled from the bad side and completely drowned the bronchi of the opposite lung. Twilight anesthesia and other prolonged anesthetic agents are contraindicated. Nitrous oxide and oxygen seem most desirable, since the patient awakens shortly after the operation.

If there is a history of large amounts of expectoration, a bronchoscopic examination must be done immediately before the chest operation so as to empty the bronchi and to prevent spilling of pus from one lung to the other. The bronchoscopic treatment should be repeated at the end of the operation if necessary. These bronchoscopic treatments should not be limited to the surgical cases but may be employed to advantage in conjunction with other conservative methods so as to prevent the spilling of pus.

When thoracic surgical procedures are being considered, special attention should be given to the position of the patient, not only on the operating table but also after his return to the ward. This attention to detail will lessen the spilling of pus to obstruct new areas, and it will minimize the possibilities of sudden or latent secondary pulmonary complications. In cauterizing the lung, hemostasis should be as nearly perfect as possible. Otherwise, blood will spill from the operated area into new regions, obstruct the normal air flow, and possibly lead to serious consequences.

I believe that many of the deaths ascribed to postoperative shock, cardiac failure, acute pulmonary edema, pulmonary embolism and cerebral embolism are really the consequences of internal drainage.

SUMMARY

The term "internal drainage" is used to designate the spilling of pus from a diseased bronchus to neighboring bronchi of either lung.

Internal drainage is a definite entity, and an understanding of it is important in both the diagnosis and treatment of pulmonary suppurations as well as in the prevention of postoperative pulmonary complications.

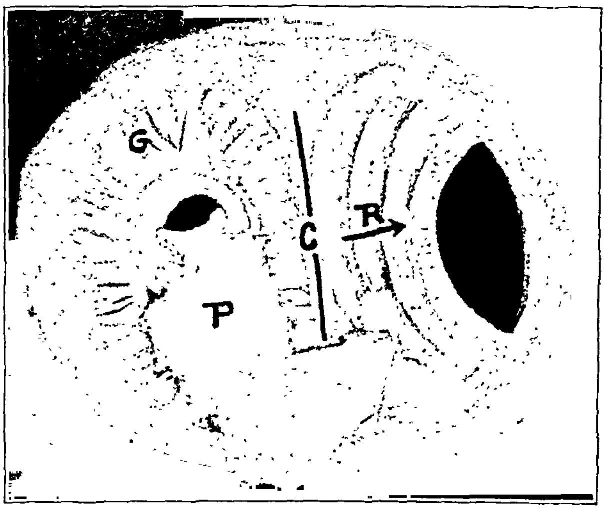

Fig. 4.—Bronchoscopic view at the region of the carina (bifurcation of the trachea) in a patient with a left-sided pulmonary abscess (diagrammatic sketch): The left main bronchus is partially occluded by a rim of edematous granulation tissue (*G*). Note the pus (*P*) spilling from the left main bronchus across the carina (*C*) into the right main bronchus (*R*). This spilling has been referred to as "internal drainage," and was observed in this patient during the bronchoscopic examination under a light ether anesthesia. (Compare with the bronchoscopic view of a normal patient, figure 5.)

Intrabronchial injections of iodized oil have permitted a study of internal drainage and of the factors on which it depends.

Pus within a bronchus may spill to predetermined areas, depending on the posture of the patient, the site of the primary lung lesion and the patency of the bronchus. This drainage is especially marked when the pus is of low viscosity and of great quantity.

The application of the principles of internal drainage has enabled me to localize more accurately the site of pulmonary abscesses, to lessen the number of patients requiring operation, to lower the operative risk, and to increase the percentage of cures.

University of California Hospital, Third and Parnassus avenues.

ABSTRACT OF DISCUSSION

Dr. John Alexander, Ann Arbor, Mich.: Dr. Faulkner has clearly shown the strong influence of posture on migration of secretions within the bronchial tree. Coughing also has a powerful influence. Fluoroscopic observation of iodized oil within the bronchi during acts of coughing demonstrates how freely the oil is moved from one portion of a lung to another or from one lung to the opposite lung, as well as toward the mouth. It may be assumed that the longer infected secretions remain in contact with uninfected portions of lung, the greater will be the chance of infection. In surgical practice these facts may be used to great advantage. Immediately before any operation, every patient who has sputum should evacuate as much as possible of his sputum by voluntary coughing and perhaps by postural drainage. Unless there is a contraindication, patients with sputum who are given a general anesthetic should be operated on in a Trendelenburg position of about 15 degrees and in some patients this position is desirable after operation. Atropine should not be given as a routine preoperative medicament because it makes the bronchial secretions tenacious and therefore more liable to occlude the bronchi and favor pulmonary infection distal to the occlusion. Neither before nor after operation should morphine be given in large enough doses to dull the cough reflex so much that there will be insufficient coughing to raise what secretions are present. Yet enough morphine should be given to allay pain to a degree that the patient is willing to cough. Abdominal or thoracic incisions should be so supported by binders and the nurse's hands that coughing is made easier. Voluntary coughing, inhalations of 5 per cent carbon dioxide in oxygen, postural drainage and bronchoscopic aspiration are useful methods under certain circumstances for evacuation of bronchial secretions after operation.

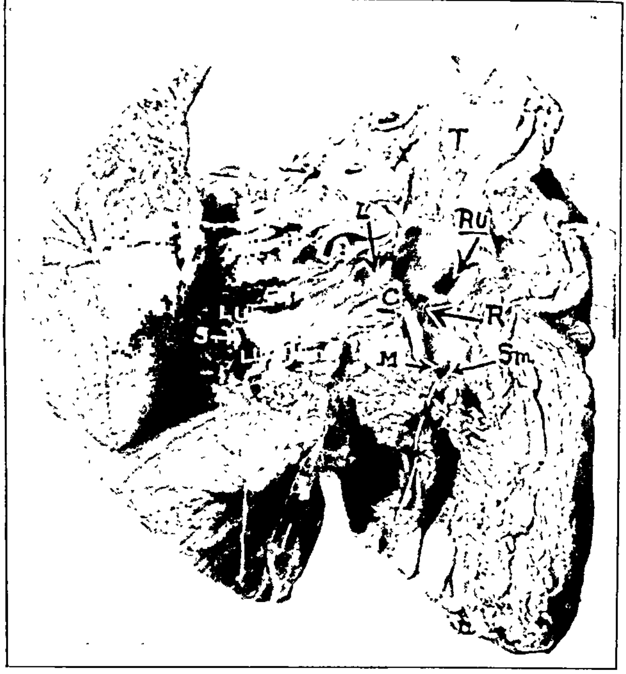

Fig. 10.—Specimen illustrating the anatomy of the tracheobronchial tree and its similarity to a system of open pipes. Free communication between the various bronchial trunks facilitates the spilling of intrabronchial secretions from one trunk to another. *T*, trachea; *C*, carina—bifurcation of the trachea; *L*, left main bronchus; *R*, right main bronchus; *RU*, right upper lobe bronchus; this opening is high up and almost directly across from the carina (*C*); *Sm*, septum between the openings of the middle and right lower lobe bronchi; *S*, septum between the left upper (*LU*) and the left lower (*LL*) lobe bronchial openings; these openings are close together, about 2 inches down from the carina.

Dr. W. P. Lucas, San Francisco: The internal drainage of pus, secretions and blood from one lobe to another occurs by the connecting system of bronchi, a sort of pump system which is open at times and closed at others, which makes diagnosis very difficult. The addition of frequent bronchoscopic examinations is therefore important not only for diagnosis but also from the standpoint of treatment. The need of iodized oil in connection with such diagnosis does not need to be emphasized to those who have used it. When the bronchoscope is used it must be used by one who is familiar with its use. I was myself surprised at the ease with which children can be made to take the bronchoscope on repeated occasions without coughing, without any disturbance, without any fear, when it is done by some one who knows how to do it.

Dr. Louis H. Clerf, Philadelphia: In the Lumleian lectures, Dr. Thomas McCrae pointed out that, in cases of bronchial foreign body, physical signs were commonly elicited over the opposite lung; they were practically always auscultatory signs. In cases of localized pulmonary abscess, the roentgenologist will often report that there is a definite increase in the bronchial shadows over the opposite normal lung; when the abscess is cured, these shadows have lessened in density. By bronchoscopy one usually observes evidences of mucosal infection of the bronchi of the normal lung. Surgeons frequently ask us to carry out a course of bronchoscopic treatments in cases of abscess of the lung or bronchiectasis before external operation is resorted to because they believe that definite improvement results, particularly in the normal lung tissue and bronchi. All of this is evidence to support the belief that secretion from one portion of the lung may be and is distributed to other portions of the tracheobronchial tree. Iodized oil should always be used as a diagnostic measure before external operation is contemplated, particularly in bronchiectasis.

Dr. William B. Faulkner, Jr., San Francisco: My experience has been similar to Dr. Alexander's, in that this internal drainage not only accounts for the physical manifestations but may lead to serious consequences, such as the development of a suppurative metastatic process in the opposite lung. Throughout this entire work it has struck me that posture has played a much more important part than cough, but I am unable to speak authoritatively on that point as yet, as we are still studying the matter. Dr. Lucas has mentioned the necessity of bronchoscopy in the treatment of these patients, and I may say that in the patients with lung abscesses whom we have seen, even though we have been thoroughly interested in the operative side and desirous of doing thoracic surgical work, we have been able to cure six patients in succession by the employment of bronchoscopy and other conservative measures—a small series, but it warrants attention. In our foreign body cases we have observed the same signs to which Dr. Clerf calls attention; that is, the physical observations will often be on the side of the chest opposite that in which the foreign body is situated.

The Danger of Sterilization.—One of the greatest dangers in the use of sterilization is that overzealous persons who have not thought through the subject will look on it as a cure-all, and apply it to all sorts of ends for which it is not adapted. It is only one of many measures that the state can and must use to protect itself from racial deterioration. Ordinarily it is merely an adjunct to supervision of the defective or diseased. Its object is to protect the public, but it must protect all of the interests of the public, not merely one of them.—Gosney and Popenoe: Sterilization for Human Betterment, New York, Macmillan Company, 1930.

NONMALIGNANT NODULES OF THE BREAST THE RESULT OF PROLAPSE *

LILIAN K. P. FARRAR, M.D.
NEW YORK

The first mastectomy recorded for prolapsed hypertrophied breast was probably that done in 1669 by Durston, who says that "when opened nothing was found but prodigious bigness (64 lbs.)." In 1857 Velpeau gave a graphic description of the operation he had performed for virginal hypertrophy of the breast. Michel and Poussin were the first, in 1897, to devise a plastic operation for prolapsed hypertrophied breasts. The first operation in Germany for a similar condition was done in 1908 by Dehne. In 1910 the surgical congress in Geneva held a discussion on hypertrophy of the prolapsed breast, and the operation for its relief.

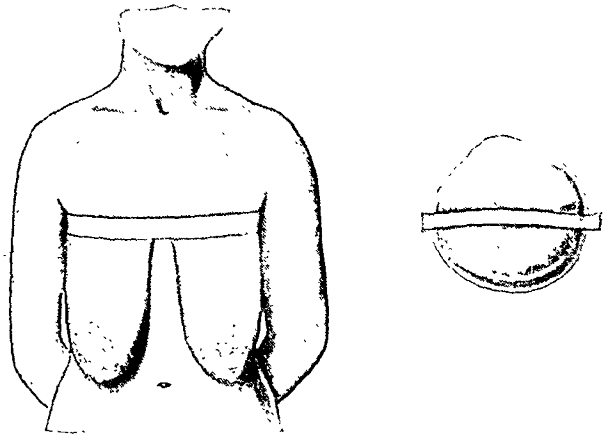

Fig. 1.—Prolapsed atrophic breasts.

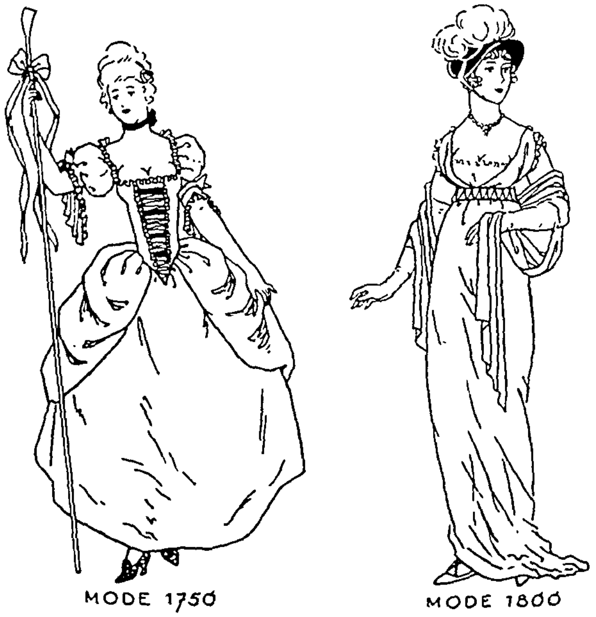

Fig. 2.—Mode 1750, the "Watteau"; mode 1800, the "Empire."

Little space has been given in the medical literature of this country to virginal hypertrophied breasts, but rather frequent mention is made of this condition and of operation in the surgical journals of Europe, especially in Germany. It was not, however, until 1923 that it began to be recognized that a new condition had arisen, and Kraske seems to have been the first to describe a plastic operation for "virginal atrophic prolapsed breasts." The prolapse was attributed correctly to the loss of fat in the breast tissues, and considered to have been caused by malnutrition. This may well be and no doubt did follow as a result of food conditions during the war. But this cannot be considered to be the cause in our own country, where prolapse of the atrophic breasts is now occurring with alarming frequency.

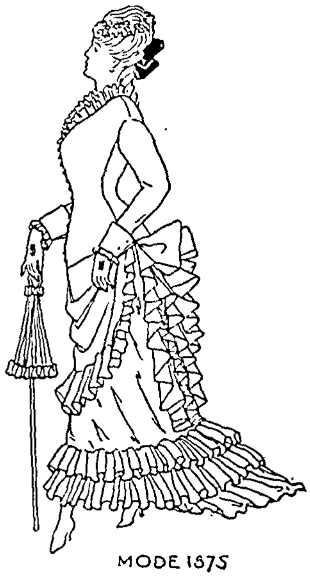

Fig. 3.—Mode 1875, the "Princess."

Fig. 4.—"The gay nineties."

It is I think the first time, certainly in centuries, that fashion has decreed an absence of breast, in the civilized races. It is true that certain of the savage tribes, notably the Hottentots, use many devices to produce the elongated prolapsed breast which is presumably a mark of beauty in that race. But certainly never in

this country until now have the breasts been actually forced down by the mode of dress. If one studies old paintings or portraits one will see that, while fashion has its vagaries in dress, the upper part of the dress, whether it be the "Watteau," the "Empire" (fig. 2), the "straight front" or the "tailor made" (fig. 3), has always given support to the breast tissues. As the bicycle, tennis and golf became popular and women took more active part in outdoor sports there came the demand for a dress that would allow more freedom for muscular action (fig. 4), and a much more suitable style of sport dress was evolved. Dame Fashion, unfortunately, soon decreed a dress for sport copied directly from the wardrobe of the young girls' brother. The "boyish form brassière" with its tight nonelastic constriction of the chest was the logical necessity after taking the boys' clothes. The practice of covering the breasts with, adhesive plaster to allow the wearing of a boyish swimming suit, or "Antibe shirt," hastened the changes in form now taking place. The fashion in sport clothes soon extended to evening dress (fig. 5) until the flat chest became *de rigeur* for all the gowns of the young girl. As the breast posteriorly is only loosely attached by areolar tissue to the fascia covering the pectoralis muscle, and attached anteriorly by the fascia to the skin over the breast and at the areola surrounding the nipple (fig. 7), the pressure brought on the soft yielding tissues of the breast soon causes the fat to atrophy and the breast to prolapse. It is not unusual now to see the breasts forced to the waist line, or even to the umbilicus. The upper part of the breast, when prolapse has taken place, is only a fold of flabby skin and the dependent portion consists of glandular tissue that seems to be made up of separate nodules, because the fat is entirely absorbed and one feels only the lobules of the breast. These nodules are frequently mistaken for new growths (fig. 8) and the breast removed in part or entirely under the belief that they are malignant. A distinguished surgeon in this country said that he had operated in a hundred cases before he found that they were not cancerous and is now leaving

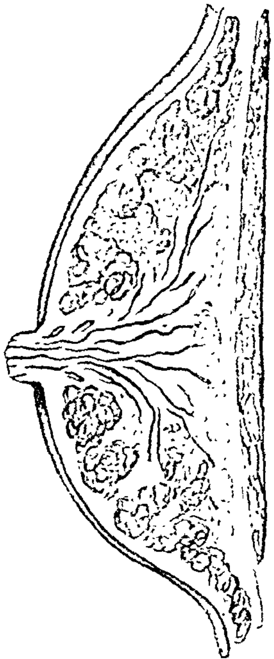

Fig. 7.—Side view of normal breast showing milk ducts and the loose attachment to the underlying fascia.

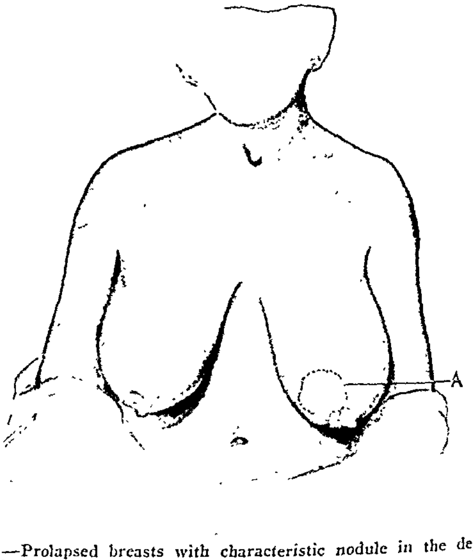

Fig. 8.—Prolapsed breasts with characteristic nodule in the dependent portion of the breast.

them alone. But can one leave them alone? Increasing prolapse may soon mean a breast that will have to be fastened at the waist line (fig. 9), as the Hottentots do, or the serious risk of mammary cancer developing from continued breast stasis.

On the other hand, the type of plastic operation now being advocated is a formidable operation necessitating lifting the nipple (fig. 10 *A*) after having made a circular incision around the areolar tissues, and thereby cutting the suspensory ligaments of Cooper and probably cutting the ampulla of the milk ducts which lie directly under the nipple. The removal of the dependent portion of the breasts takes away the glandular secreting tissue (fig. 10 *B*). If the argument is made that sufficient tissue is left for nursing, the fact must be recognized that the ducts have been, at least in part, destroyed (fig. 10 *C*) with consequent inability to nurse from portions of the breast because of loss of ducts; and then arises the danger of "caked" breast and abscess in the nursing mother. Last, but certainly of great importance, is the mutilation of a young girl. The ugly scars, the shock and mortification are not easily to be borne by the young. Fortunately in the young, and the majority of these patients are under 25, the tissues will respond to a properly applied breast support (fig. 11). This should be made of a light elastic webbing and fastened by elastic lacings in the back with two firm straps over the shoulders that may be buckled in front, or in the back if desired, especially when evening dress is worn. The results in approximately fifty cases, which have either been followed personally or reported by physicians who have referred their patients in consultation, have been so satisfactory that I believe I can say it is the only way really to restore the atrophic prolapsed breasts occurring in young girls.

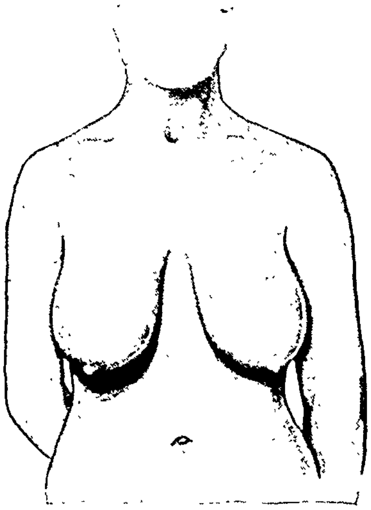

Fig. 9.—Same patient after wearing supporting brassière two months: total disappearance of the nodule seen in figure 8.

CONCLUSIONS

1. Prolapse of the virginal atrophic breast is occurring with alarming frequency in this country owing to the present fashion in dress.

2. There is danger of permanent prolapse of such a breast, and perhaps danger of cancer developing from prolonged stasis of breast tissue.

3. Plastic operation for prolapsed atrophic breasts is an unnecessary mutilation of a young girl.

4. Plastic operations on prolapsed atrophic breasts will deprive nursing mothers of breast tissue and milk ducts with too little tissue left for nursing and possibly "caked" breasts and abscesses of the breasts as a result.

5. The change of dress with proper uplifting support of the breast will cure the condition if treatment is begun early.

ABSTRACT OF DISCUSSION

DR. GEORGE GRAY WARD, New York: Dr. Farrar has called to our attention at the Woman's Hospital for a number of years past the frequency with which we come across nodules, small in type, that occur in the breasts of comparatively young women and which cause us some doubt as to whether we should operate on them or not; in other words, whether we should make a biopsy or not to prove whether they are malignant. This happens so frequently, and so many times we find that the nodules are not malignant, that we have paid attention to what she has said about the fact that many of these cases are brought about through the method of dress today, pressure on the breasts, and we feel that in those cases in young women this should be given consideration, and the case should be studied before we hastily remove a supposed nodule. The proper support of these breasts, proper instruction, insisting on lack of all constriction, which is quite a common thing among many of these girls who desire to have a boyish figure, has resulted in the disappearance of the lumps in a number of cases. Recently I had my attention called to the

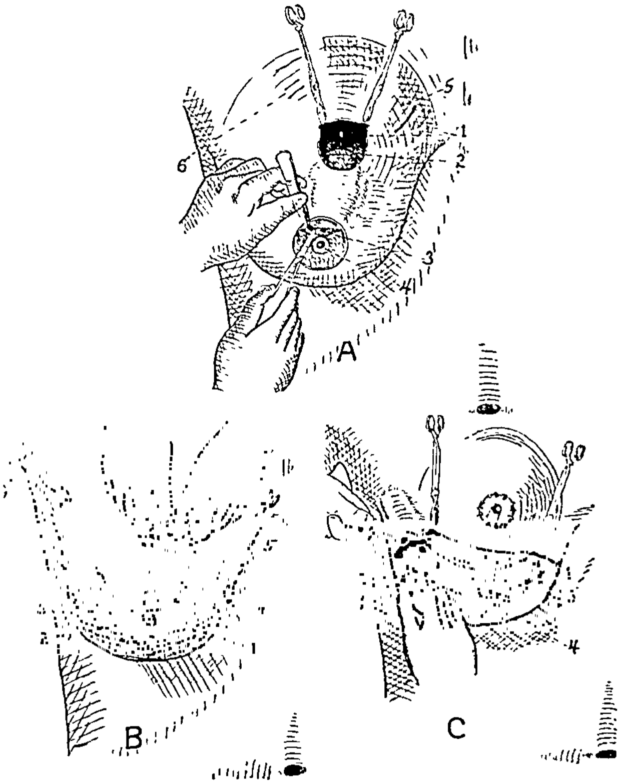

Fig. 10.—The mutilating type of operation that has been frequently recommended for atrophic prolapsed breasts: *A*, the opening for the nipple when excised; *B*, nipple being drawn upward into the artificial opening; *C*, excision of glandular breast tissue with consequent injury to the milk ducts.

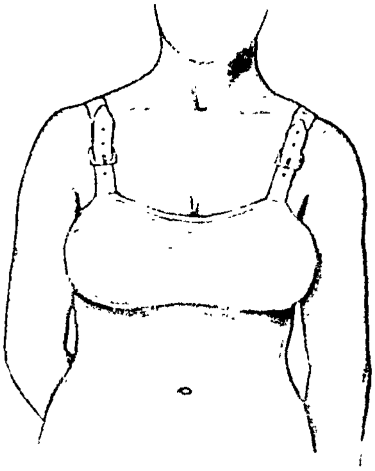

Fig. 11.—Brassiere to support and restore the prolapsed atrophic breasts. The shoulder straps are adjustable and the brassiere is laced in the back.

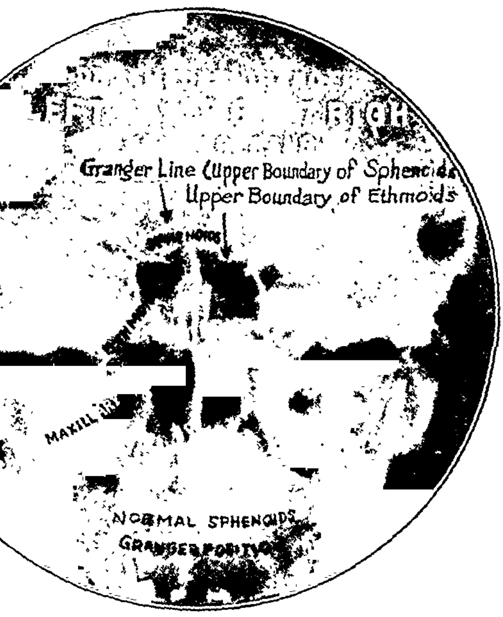
operation for lifting breasts that were markedly prolapsed, and also in cases of extensive hypertrophy, by a surgeon in New York who showed a number of photographs before and after, and the technic he used, and at his request I allowed him to give a demonstration at the Woman's Hospital of this operation on a case in a young woman who had pendulous breasts. The operation is certainly a most formidable one. It took between two and three hours to do, and it undoubtedly, as I saw it, means the sacrifice of gland-bearing tissue which may be of value to that woman should she become pregnant later. I believe that the operation is not justifiable in young women and should be used only in these extreme cases of excessive hypertrophy and deformity, and the dangers of operation should be emphasized so that the patient has her choice and knows what she is doing.

ROENTGEN EXAMINATION OF THE PARANASAL SINUSES AND MASTOIDS *

AMÉDÉE GRANGER, M.D.
NEW ORLEANS

During the meeting of this section at San Francisco in 1923 it was my privilege to describe [1] in detail two positions for making roentgenograms of the paranasal sinuses, more especially the sphenoids and ethmoids. I adopted these after painstaking experiments with dried skulls which had the sphenoids and two groups of ethmoids filled with substances of different ray-absorbing values, because in these roentgenograms the shadows of the filled sinuses were superimposed or merged to the least extent and, much more important, the boundary landmarks of these sinuses formed by known and constant anatomic structures were readily visible in them.

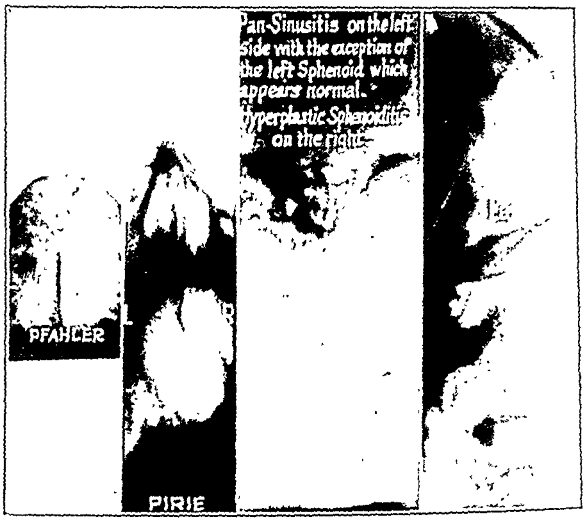


Granger Line (Upper Boundary of Sphenoids
Upper Boundary of Ethmoids
NORMAL SPHENOIDS
GRANGER POSITION

Fig. 1.—Normal sinuses in Granger position.

For the study of the sphenoid and posterior ethmoids as perfect a roentgenogram as is possible is made from this position,[2] the head resting evenly and firmly with the alveolar and glabella points in contact with the author's sinus mask or head rest, its sagittal plane forming a 107 degree angle with the table, and the central ray directed perpendicularly to the latter.

Before and since that meeting I have made roentgenograms of filled skulls in all the other positions that have been recommended and I am convinced that these do not show the same constant and clear anatomic boundary landmarks for the sphenoid and ethmoids and in all but two the shadows of the filled sinuses were superimposed to a far greater degree.



an-Sinusitis on the left side with the exception of the left Sphenoid which appears normal.
yperplastic Sphenoiditis on the right.
PFAHLER
PIRIE

Fig. 2.—Sphenoids and posterior ethmoids in the Pfahler, Pirie, Granger and lateral positions.

During the past seven years in my hospital service alone I have made more than 5,000 roentgen examinations of the paranasal sinuses and I am convinced that a careful study of the roentgenograms made in the two positions I advocate will furnish all the information necessary for a diagnosis. I admit readily that the injection of iodized oil in the sinuses will often bring out more clearly and with greater detail pathologic changes present in the sinuses, but I am also certain that in the vast majority of cases these changes could have been seen by more experienced or careful observers in roentgenograms made *without the injection* of the iodized oils.

In interpreting the sphenoid view (fig. 1) I have learned to place great reliance on the appearance of the upper boundary of that sinus, the curved (Granger) line.

When that line is distinct with clean-cut and sharp upper and lower edges, the sphenoid sinuses do not contain pus or polyps and their lining membrane has not undergone hyperplastic or degenerative changes. This is demonstrated in a most convincing manner by the following case history: A white woman, aged 36, was admitted to the hospital with a temperature of 104 F., a high leukocyte count, cellulitis of the left side of the face, sinus near the inner canthus of the left eye and the left nares completely occluded. Clinical diagnosis of pansinusitis including the sphenoid on the left side was made. Roentgenograms revealed (fig. 2) the left sphenoid and posterior ethmoid regions so opaque in the Pfahler and Pirie films that only one interpretation was possible: that these sinuses were filled with pus. In my film the Granger line is distinct and sharp on the left side, and less dense and distinct with its edges not so clear-cut on the right. On the strength of that finding and in the face of the contradicting clinical and other roentgen observations, I sent in a report that all the sinuses on the left side contained pus excepting the sphenoid, which was clear and appeared healthy, and that there were some hyperplastic changes in the right sphenoid. At operation, pus was found in the left frontal, maxillary and ethmoids, but none was found in the sphenoid after it had been freely opened, as it did not seem possible to the rhinologist that with so many pathologic changes in the other sinuses and so much occlusion of the nares interfering with proper drainage the sphenoid could have escaped infection. He not only found no pus, but the mucosa appeared perfectly healthy. The normal opening of the right sphenoid was then enlarged; it contained no pus, but its mucosa was thickened and slightly discolored.

* From the Departments of Roentgenology of the Charity Hospital and of the Graduate School of Tulane University.

* Read before the Section on Laryngology, Otology and Rhinology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

[1] Granger, Amédée: Positive Identification of the Sphenoid and Ethmoid Sinuses, J. A. M. A. **81**: 1336 (Oct. 20) 1923.

[2] Granger, Amédée: Roentgen Examination of the Sphenoid Sinuses, Radiology **6**: 23 (Jan.) 1926.

This last condition, hyperplasia without pus or polyp so frequently diagnosed or suspected by the rhinologist, causes little or no increase in the density of the sphenoid image and it is therefore difficult if not impossible to recognize in roentgenograms made in other than my sphenoid position because those made in other positions have no Granger line to study and their interpretation is based solely on changes in the density of the sinus area; and it has just been shown that the density of the sphenoid image can be increased to a marked degree by pathologic changes entirely outside that sinus.

For the examination of the mastoid regions, roentgenograms are made in the position recommended by Law and in that described by me to the Section on Radiology during the 1926 session of the American Medical Association in Dallas.[3]

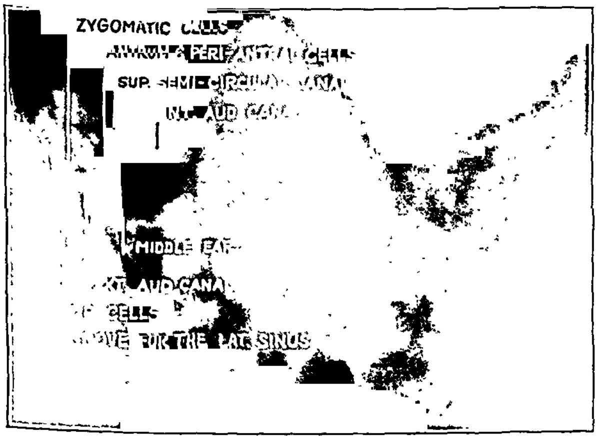

Fig. 3.—Normal mastoids in the Granger position.

The Law roentgenogram has been standard in this country for a number of years and needs no description to the members of this section.

The Granger roentgenogram (fig. 3) gives a more detailed view of the anatomy of the mastoid region and process with fewer structures superimposed. It shows the different groups of cells, including the tip cells, much more distinctly; the superior semicircular and internal auditory canals; the sharp outline of the mastoid cortex; and in this view the course of the external auditory canal is away from and does not overlie the shadow of the mastoid cells.

For these reasons a study of these roentgenograms makes it possible to state whether or not the mastoid cells are clear in cases of furunculosis of the external auditory canal with cellulitis of the external ear and in cases of periostitis of the mastoid process. Both conditions render the mastoid region so cloudy or opaque in the Law roentgenogram as to make such a differential diagnosis impossible.

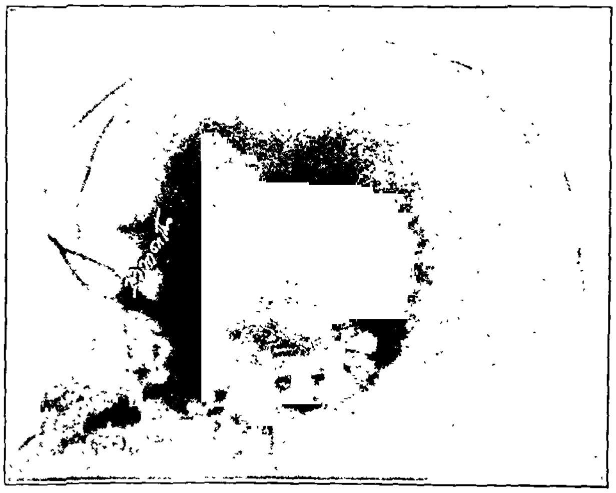

Fig. 4.—Normal mastoid of an infant, aged 2 years.

Because the superior semicircular canal and surrounding mastoid structure are clearly visible, I was able to make the diagnosis of labyrinthitis in several instances and to have the diagnosis confirmed by the usual otologic tests. And because the outline and course of the internal auditory canal is also clearly visible in these roentgenograms, I was able to make the preoperative diagnosis of tumor of the acoustic nerve in two cases referred to my hospital service from the neurologic service of that institution with the clinical diagnosis of probable brain tumor.

In infants and children under 6 years of age the Law position is the only one that can be satisfactorily employed. For the past three years I have made an intensive study of the roentgenograms of these little patients, and last December in Toronto I presented the result of that study to the Radiological Society of North America.[4] Briefly summarized, this contribution contained the three following important observations:

1. The shadow outline of the sinus plate (anterior wall of the lateral sinus and groove for the lateral sinus) normally seen in the Law roentgenograms of the healthy mastoid of adults is not seen normally in those of the healthy mastoids of infants under 2 years (fig. 4) and rarely under 3 years of age, and when it is seen in the absence of clear and unusual pneumatization it means extensive destruction of the mastoid down to the sinus plate (fig. 5).

2. In a number of cases too large to be attributed to mere hazard or coincidence, infants and babies with definite signs of infection and occlusion but not of

[4] Granger, Amedee: A Positive Sign of Extensive Destruction of the Mastoid of Infants, Radiology 14: 495 (May) 1930.

softening and destruction of the mastoid were greatly improved by the irradiation incidental to the making of the roentgenograms and went on to resolution and cure. This observation was confirmed by several competent otologists and was especially noticeable in some patients who, prior to the roentgenographic examination, had run a slow, low grade course over a period of several days without showing any improvement.

3. In a number of cases, much larger than would be expected, the amount of softening and destruction revealed in the roentgenogram and found at operation was out of all proportion to the clinical manifestations. If this is seen, no matter how indistinctly or how blurred, in the roentgenograms of infants less than 2 years of age it means extensive destruction of the mastoid down to the sinus plate. On the other hand, if it is not seen even in a poor roentgenogram of the mastoid of infants less than 2 years of age it means that extensive destruction of the mastoid does not exist.

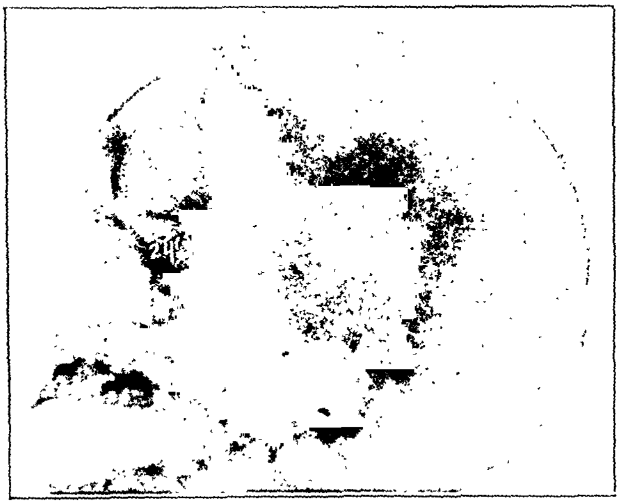

Fig. 5.—Diseased mastoid of an infant, aged 2 years, with the author's sign of extensive destruction present.

ABSTRACT OF DISCUSSION

Dr. Lawrence Reynolds, Detroit: The sphenoid and ethmoid sinuses give the roentgenologist, as well as the otologist, the greatest difficulty in proper interpretation. Undoubtedly, the method Dr. Granger has described, in addition to other methods, will ultimately lead to a better diagnosis of these obscure cases. It is the borderline cases that give the greatest difficulty, and in those cases the various positions described by Dr. Granger would be of great help. The method I usually employ is that advocated by Pfahler and Pirie. I have not used Dr. Granger's method as much as I might. His method of examining the mastoid is interesting because it enables one to see "around the coroner." The examination is commonly made in the usual or modified Law position, but Dr. Granger's position undoubtedly gives an idea of the tip cells which the Law position does not in a majority of cases. I am extremely interested in his sign of mastoid involvement in infants. At Harper Hospital the mastoids of infants have been examined and a number of cases have been seen. Cheadle was the first to point out the three types of mastoid found in infants. He classified these as: (1) diploetic, or dense form, (2) pneumatic infantile type, and (3) adult type of pneumatic structure. In surgical cases from a given group it was found that 40 per cent fell within the first five-year period, and this being true, it was of tremendous importance to determine as accurately as possible from the films the amount of involvement and the type of structure. The pneumatic infantile type and the adult type of structure predominated in the patients of 5 years of age and under. Lang was among the first to point out the importance of roentgen examination in mastoid diseases, and he divided the roentgen appearance of the mastoid into: normal mastoid; mild, or first degree mastoiditis, in which there is replacement of air content with exudate but no actual change in the cell walls; second degree, in which there is noted, in addition to the presence of exudate, coalescence of cells, with softening and breaking down of the trabeculae; and third degree, in which practically all the cell structure is broken down. Roentgenographically, the first degree is not considered surgical, whereas the second degree, namely, where there is considerable or complete obliteration of normal cell structure, together with breaking down of the trabeculae, is considered a surgical mastoid.

Dr. Burt R. Shurly, Detroit: The checking of observations by operation, and recording them with films, is exceedingly valuable for future reference and gives a record that will establish a definite understanding of the degree of error, which may vary from 5 to 20 per cent according to skill and observation. The point of view of the radiologist has been given, but in the final analysis who takes the responsibility? The otologist! So when otologists want to bury their mistakes they have to take those of the radiologist along with them sometimes. It is my custom to roentgenograph all suspicious sinus cases, but I rely on the clinical evidence, history and examination to determine the probability of disease. Negative roentgen observations do not rule out the possibility of pathologic changes in sinuses. In regard to the interpretation of the sphenoid in figure 1, my answer would be that this was the work of an expert; but a borderline observation becomes more difficult in the hands of those radiologists who are not really interested in head work, or in the hands of the otolaryngologist of lesser opportunity, skill or interest along these lines. I believe that operation on the mastoid or sinuses should not be undertaken without the aid of careful roentgen study, with the exception of emergencies and unusual circumstances. In regard to the second contention, that a large number of cases go on to resolution and cure as the result of irradiation while the film is being taken, I challenge this statement. Many of my patients recovered before the days of the x-rays who were not operated on. Sitting in the sun, eating vitamins, and the pranks of old Dame Nature are just as valuable now as they were long ago. The value of radiology in the interpretation of abnormalities of the sinuses and mastoid is alone worth the effort and expense. I believe it is of the utmost importance that the rhinologist and laryngologist should hitch up with a competent radiologist who is especially interested in this work, and with whom the films can be talked over in each case. The interest and knowledge one attains can be developed in this way.

Dr. Harry L. Baum, Denver: One point made by Dr. Granger is worth stressing, and that is the importance of standardization of the positions in which roentgenograms are taken, so that the position for every patient may always be exactly the same. Thus a definite technic will be followed consistently in every case studied, whether sinuses or mastoids. I have used Dr. Granger's sphenoid position in many instances, and have studied it with a great deal of interest. When it first came to my attention I hoped that my problem was solved so far as sphenoid work was concerned. Further study of the position and of the patients, however, over a period of several years has led me to the final conclusion that although the position has its value—and I say this with the greatest respect for the work Dr. Granger has done—it does not give the final answer in every case of sphenoid diagnosis. There are several reasons for this which I think I am justified in mentioning. It must not be forgotten that the greatest variation in the pneumatization of the sinuses takes place in the ethmoids and the sphenoid. For example, the posterior ethmoid cells may extend back into the anterior or upper part of the sphenoid body so that the observations in the Granger position are entirely invalidated. In fact, I have an anatomic specimen in which both ethmoids have extended across the upper portion of the face of the sphenoid to join in the midline. Also, sphenoid pneumatization on one side may extend into the opposite side so that one cavity occupies practically the whole of the sphenoid body. Thus, one might be led to conclude that disease was present in both sphenoids when in reality only one was involved. And these are but examples of the numerous variations that can and do take place in the pneumatization of the sphenoid, many of which might invalidate the observations in the Granger position. The diagnosis by means of this position must be governed by one's interpretation of the changes that appear to have taken place in the upper anterior angle of the sphenoid, or the bone which forms that angle, with the addition of the effect which the presence of contained secretion may add by its gravitation downward and forward into the angle when the head is placed in the Granger position.

Dr. Amédée Granger, New Orleans: In the short time allotted it was quite impossible to cover the first part of the subject fully. I was suggesting not a technic that is to be used to the exclusion of every other position or technic but one that can be used with good results in a majority of cases and will be found sufficient. There will always be special conditions that will require the use of other positions. Dr. Reynolds is not so far away from my conclusions as would appear from his statement. Under 5 years of age, pneumatization is present. The works of Kirrisson and Politzer make that point clear. Between 2 and 5 the infant mastoid approaches the adult type and one can then see the outline of the sinus plate. Under 2 years of age, the sinus plate is not seen unless there is destruction or unusual pneumatization.

When there is unusual and early pneumatization, or when the sinus plate is superficially situated, there is not much cancellous bone overlying it and its shadow becomes visible. If the sinus plate can be seen and the cancellous bone structure or the cellular structure can be made out, the mastoid that is being dealt with is healthy. But when one side is apparently clear, with no bone or cellular detail visible, there is destruction. I am sorry that I cannot agree with Dr. Shurly about the inefficiency of the therapeutic value of fractional doses of the x-rays in these cases.

I have seen from twenty-five to thirty cases of gastro-enteritis with discharging ears in infants convalescent from bronchopneumonia and otitis media. As a rule, these little patients die. These little patients were roentgenographed and those showing the sign of destruction of the mastoid were operated on. Those who were strong enough to survive the shock of the mastoidectomy got well of the gastro-enteritis. Two in whom there was no actual sign of breaking down or destruction of the mastoid got well of the gastro-enteritis after these fractional doses of the x-rays. After seeing from fifty to sixty patients with mastoiditis without bone destruction get well with fractional doses of the x-rays, one cannot feel that it is an accident.

Measuring Intelligence.—G. Stanley Hall . . . tried, at least once, every new thing that came out. In the case of the intelligence tests, however, anxious to prove to himself that he was not weak-minded, he tried many. First of all, he tried a well known assembling test which has been largely used in the army but was new to him. After fifty minutes, he failed to complete the work, "but all these stunts were done in eight minutes by an assistant in the laboratory workshop." Then he took up one of Thurston's tests for freshmen entering college. The time allotted was twenty minutes, and Hall succeeded in completely mastering it in thirty-eight minutes. On the second Thurston test, however, he fell down. After fifty-four minutes of hard work, there remained several questions which he could not answer. "Here," Hall says, "my time was about twice too long so that my marks should be about 50 on the scale of 100—and from this should be discounted failure to answer 5 per cent of the questions." As a result of this bad showing, Hall felt that he had been too ambitious, so he took up Meyers' tests for young children in the grades. He was told to draw "a line from the first circle to the last circle that shall pass below the second and fourth circles and above the third and fifth circle" and much more of the same thing. Here he scored another failure. He was required as he said, to hold in memory, after one hearing, about fifty words and this he couldn't do—Swift, E. J.: The Psychology of Childhood, New York, D. Appleton & Co., 1930.

INDICATIONS FOR AND RESULTS OF CONSERVATIVE OPERATIONS ON THE KIDNEYS *

WALTMAN WALTERS, M.D.
ROCHESTER, MINN.

In a consideration of conservative operations on the kidney, I have grouped the cases into (1) those in which there is obstruction usually due to stone in the ureter, pelvis of the kidney, or the calices; (2) those in which obstruction similarly situated, not the result of calculi, produces hydronephrosis, and (3) those in which a diseased portion of a duplicated kidney exists. On a previous occasion, I presented the results following conservative operations in the latter two groups; namely, successful resection of the renal pelvis and removal of the infected hydronephrotic portion of a duplicated kidney. I shall therefore refer to these groups briefly. After the passage of another year I still believe firmly that, if sufficient renal parenchyma remains, such kidneys can be preserved.

HYDRONEPHROSIS

In June, 1930, I reexamined a patient whose right renal pelvis had been resected eighteen months previously for hydronephrosis and whose left renal pelvis had been resected for hydronephrosis fifteen months previously. Prior to the first operation, pain, chills and fever had been present over a period of months; the capacity of each renal pelvis varied from 200 to 350 cc. and the pelves contained infected urine. The patient is now in good health, has gained 20 pounds (9 Kg.) and has not had evidence of urinary obstruction. Cystoscopic examination and estimations of the function of each kidney show the kidneys to be functioning satisfactorily; neither kidney contained residual urine. The right kidney excreted a maximal amount of indigo carmine and the urine from it did not contain pus. The function of the left kidney which, prior to operation, was the poorer of the two kidneys, although still below normal had improved since operation. I have under my care three other patients with similar types of obstruction on whom a similar type of operation has been done on one kidney successfully; the other kidney will probably be operated on in two or three months, or as soon as the condition of the patients permits. In my review of the literature I have not found a report of another case of successful bilateral resection of the renal pelvis for hydronephrosis.

The beneficial effects of simple ligation and division of anomalous obstructing renal vessels, producing moderate hydronephrosis only, should be remembered. A case in point is that of a young woman with bilateral polycystic kidneys, the right kidney being obstructed by anomalous renal vessels. In May, 1929, these vessels were divided and ligated. Subsequently, there has been relief of symptoms of urinary obstruction. In another case of renal colic in which there was uniform but not marked dilatation of the left renal pelvis and calices, ligation and division of two anomalous arteries and one vein relieved the patient of symptoms of obstruction in the urinary tract.

In connection with the foregoing cases, attention should be called to the fact that heminephrectomy or resection of a portion of the kidney will probably be most successful if arteriosclerosis is not present. The possibility of bleeding from an open-mouthed sclerotic branch of a renal artery, after resection of the kidney, may necessitate nephrectomy, and therefore the existence of arteriosclerosis must be carefully weighed in making a decision as to whether conservative operation of this type should be attempted.

* Read before the Section on Surgery, General and Abdominal, at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

URINARY CALCULI IN PRESENCE OF UNIMPAIRED RENAL FUNCTION

It is well to emphasize that renal or ureteral calculi will often produce enough obstruction to the passage of urine or reflex disturbances of unknown type to interfere with the excretion of any medium used in determining the differential function of the individual kidney, and thus lead to uncertainty as to the functional capacity of the kidney carrying the stones. With a history of renal obstruction, the finding of a shadow or shadows in the renal pelvis, calices or ureter, cystoscopic examination may show abnormal function of the kidney so obstructed and lead to the erroneous assumption that the kidney is destroyed, particularly if the symptoms have been present for a long time, when as a matter of fact the obstructive stone may have produced obstruction only recently. In such cases, especially if a ureteral calculus is present, it is advisable to remove the stone from the ureter and await the development of other indications leading to sufficient clinical evidence to remove the kidney.

A woman, aged 50, came to the Mayo Clinic, Aug. 7, 1929, with the history that in January, 1929, she had had three attacks of left renal colic in a period of ninety-six hours. It was said that a stone had been found in the ureter and had been pushed back into the pelvis of the kidney. Blood and pus were noted in the urine. Since then the patient had not had colic. The urine contained pus graded 1; a test of renal function showed blood urea 20 mg. for each 100 cc. A roentgenogram of the kidneys, ureters and bladder showed the shadow of a stone in the lower part of the left ureter 1.5 by 1 cm. After the injection of phenolsulphonphthalein there was excretion of 20 per cent from the right side and none from the left side in fifteen minutes. Excretion of indigo carmine was graded 2 + on the right and 1 + on the left. A pyelogram showed the pelvis and calices of the left kidney to be dilated, graded 3 to 4, and apparently incompletely filled. August 15, left ureterolithotomy was done. The ureter was large and there was considerable inflammation around it. It seemed advisable to remove the ureteral calculus, reserving decision until later as to whether nephrectomy was to be done. The patient's convalescence was uneventful. September 5, a cystoscopic examination and a differential functional test of the kidneys showed excretion of indigo carmine from the right kidney to be graded 4 and from the left kidney to be graded 3; there was slight infection in the left kidney. September 6, the patient was dismissed from the hospital; the wound was healed and the general condition excellent. Subsequent letters from the patient reported her condition to be excellent with no further pain; she has gained 10 pounds (4.5 Kg.). The urine was normal except for a few pus cells.

Interesting in this respect is a small group of cases of dilatation of the upper portion of the urinary tract, possibly neurogenic in origin, or the result of contracture of the vesical orifices of the ureters. In some of these cases calculi develop as the result of this obstruction. The removal of the calculi and the relief of the obstruction by plastic operation on the ureteral orifice may result in relief of the obstruction to the extent that the symptoms subside and the function of the kidney improves. In August, 1929, I removed three calculi from the right ureter of a patient who had had intermittent right renal colic for five years. There was also a history of hematuria with considerable pyuria and dysuria. The pyelogram showed dilatation of the renal pelves, calices and ureters. Dilatation was much more marked on the right side than on the left; the ureter was angulated and calculi were lodged at the points of angulation. After removal of the calculi, cystoscopic examination showed that excretion of indigo carmine from the right kidney was graded 2, and from the left kidney was graded 3. In March, 1930, six months after the operation, the patient reported excellent progress since the operation; she had not had colic or fever and had gained 35 pounds (16 Kg.).

MULTIPLE RENAL CALCULI AND LARGE BRANCHED STONES

A group of cases was studied in which multiple stones, including a large branched stone (sometimes called the stag-horn stone) completely filling the pelvis and calices, were successfully removed. In these cases nephrectomy is considered by some to be the operation indicated. The decision whether to remove the kidney or to preserve it should be dependent on the condition of the kidney and not on the technical difficulties of the conservative operation of pelviolithotomy or nephrolithotomy nor on the opinion held by some that such kidneys, if relieved of stones, will quickly form others. Experience in the Mayo Clinic, however, has been that stones reform in the kidney only rarely provided there is satisfactory renal function and adequate drainage. Unless an accurate method is used of ascertaining the completeness of the removal of renal calculi, such as immediate fluoroscopic examination, or a roentgenogram at the time of operation, there is a possibility of a stone or stones being overlooked in the kidney.

In February, 1930, I removed twelve calculi from the left renal pelvis and calices of a woman, aged 33, who had had intermittent left renal colic with chills and fever for a year. The largest stone was pyramidal and 2 cm. in diameter; the others varied from 2 mm. to 1 cm. in diameter. Because of the normal appearance of the solid portion of this kidney and of its large size, I preserved it. The patient returned to the clinic for reexamination two months later. She had gained 15 pounds (6.8 Kg.) and was not having renal colic or fever. The estimation of renal function prior to operation in this case showed that the left kidney was not excreting indigo carmine, but three months after the removal of these stones its function was normal, as evidenced by the fact that excretion of indigo carmine was graded 4. On both examinations, the function of the right kidney was normal.

It is my practice to advise operation in cases in which a large branch stone fills the renal pelvis and the ureter, if there is renal colic, hematuria or renal infection. Experience has shown that in many of these cases the entire stone may be removed completely; it is usually necessary to break the stone in two portions and again to check the accuracy of complete removal by means of the fluoroscope at the time of the operation. In a presentation of cases of this type on a former occasion, attention was directed to the fact that probably one of the important steps to insure success of the operation is conversion of the pelvis and calices temporarily from a closed into an open cavity by insertion of a catheter through the cortex following removal of the stone.

CALCULI IN THE PRESENCE OF SERIOUSLY IMPAIRED RENAL FUNCTION

The problem of treatment is difficult in the presence of marked disturbance of renal function, destruction of renal tissue, and calculi, especially bilateral calculi. Conservative operation in this group of cases is essential. Striking improvement has been noted in renal function and in the patient's general condition as the result of the removal of such calculi.

Attention is called to the case of a woman, aged 31, who had had intermittent renal colic, fever and pyuria for eight months. Right nephrolithotomy had been performed elsewhere and she presented herself at the clinic in December, 1928, complaining of continuation of her former symptoms. Shadows in both renal areas were noticed and partial renal insufficiency was evidenced by an accumulation of 65 mg. of urea in each 100 cc. of blood. Cystoscopic examination showed pus graded 2 in the urine from both kidneys; excretion of indigo carmine from the right kidney was graded 2 and from the left kidney graded 1. Left pelviolithotomy was done with removal of a large triangular stone, and one month later right pelviolithotomy was done with removal of a stone approximately a fourth the size of the other. The postoperative course was uneventful and the patient was dismissed in February, 1929, in good condition. She returned to the clinic in June, 1930; she reported a gain of 24 pounds (10.9 Kg.) and stated that her condition had been excellent without evidences of renal disturbance. Cystoscopic examination, June 7, showed excretion of phenolsulphonphthalein to be, in fifteen minutes, 5 per cent from the right kidney and 5 per cent from the left kidney. The blood urea was normal and roentgenograms of the kidneys, ureters and bladder did not show shadows of stones.

Another case of somewhat similar type was that of a man, aged 36, with bilateral pyelonephritis, impaired renal function, and calculi in the left kidney. He had had intermittent hematuria, left renal colic, and fever for one and a half years. The right kidney contained pus, graded 2, with excretion of indigo carmine, graded 2. The left kidney contained a large stone filling the pelvis and calices; excretion of indigo carmine from the left kidney was graded 1. The operation, in April, 1930, showed the kidney to be lobulated and two-thirds normal size. Under ordinary circumstances, the decrease in the size of the kidney and its abnormal appearance would have led to nephrectomy, but in view of the infection persisting and the reduction in the function of the right kidney, pelviolithotomy was done. The postoperative course was uneventful and the patient was dismissed from observation fourteen days after operation with the wound healed and the general condition excellent. Cystoscopic examination a week later showed function of the left kidney to be a little more than half of normal, and the urine to be free from pus; the function of the right kidney was reported to be slightly reduced; the urine was free from pus.

SUMMARY

A sufficient number of successful cases of conservative renal pelvic resection for hydronephrosis and heminephrectomy have been reported to emphasize the value of conservative operation in such cases rather than nephrectomy, provided a sufficient amount of normal renal parenchyma remains.

Beneficial results follow simple ligation and division of anomalous renal vessels which obstruct the ureteropelvic juncture and produce hydronephrosis.

Renal or ureteral calculi will often produce enough disturbance of renal function to lead to an erroneous assumption that the kidney may be partially or even totally destroyed, but that such is not the case is evidenced by satisfactory function of the kidney after the removal of as many as eleven stones, or of a staghorn stone filling the pelvis and calices.

Seriously injured kidneys, containing calculi, may show remarkable restoration of function following the conservative operation of pelviolithotomy.

ABSTRACT OF DISCUSSION

Dr. Henry G. Bugbee, New York: Even with the possession of all possible data in a given case, it may be necessary for the surgeon to make his decision at operation as to whether a conservative operation or a nephrectomy should be done; the best of surgical judgment is here brought into play, and more than ordinary surgical skill is necessary for obtaining successful results, if a plastic operation is advisable. While the frequency of bilateral kidney disorder, and of its subsequent appearance in its fellow after the removal of one kidney, must always be borne in mind; at the same time, the possibility of leaving a dead kidney, or one that will drain poorly, must also be considered. The work of Hinman on renal counterbalance has shown how one kidney may become functionless as the opposite organ undergoes compensatory hypertrophy; on the other hand, all have seen a seriously damaged kidney resume fair function after the disease condition has been removed. Last year, Dr. Walters presented a series of carefully selected cases in which he had carried out plastic operations on the kidney pelvis and ureters, and also a heminephrectomy. He showed preoperative and postoperative pyelograms and gave functional kidney tests. His operative results were excellent; only in one instance was a secondary nephrectomy necessary. Such excellent results have rightly encouraged Dr. Walters to report further conservative operations on the kidney. His results in cases of obstruction from stone in the ureter or kidney pelvis or calices, from similarly located obstructions, not the result of calculi, in resection of a diseased portion of a duplicated kidney and a large solitary cyst, are equally brilliant.

The cases that Dr. Walters has reported demonstrate the great importance of preoperative study, judgment and skill at operation, and the importance of postoperative study, if conservation operations on the kidney are to result successfully.

Dr. W. F. Harper, Selma, Ala.: I have had experience with one case which emphasizes the facts brought out in the paper. A youth, aged 19, had a fracture of the cervical spine, which resulted in a double infection of the kidneys. The left kidney finally became completely blocked, requiring a nephrectomy. At this time the left kidney was full of stones and multiple abscesses, and the pelvis was full of thick, creamy pus. Three weeks after the left nephrectomy, the right kidney, having had good function at the time of operation, became completely blocked. Repeated attempts with the cystoscope were made, but I was unable to unblock the right kidney. The temperature rose to 109 F. in the axilla. The right kidney was explored. It was a mass of abscesses and the pelvis was chock-full of thick, creamy pus and many stones. When the pelvis was opened, the pus must have jumped out for at least two feet. The patient remained unconscious for three days, with a temperature around 106 F. This was six years ago. Since then the same kidney has been operated on four times, stones being removed each time. The last time, six months ago, two stones were removed from the kidney, and no new stones have formed since then. The boy has gained 40 pounds (18 Kg.) and is carrying on a large business successfully.

Dr. George W. Reese, Shamokin, Pa.: What symptom or symptoms guide the surgeon in what has been demonstrated here as dormant stones?

Dr. Waltman Walters, Rochester, Minn.: The earliest plastic operations for hydronephrosis were done by Küster and Finger. Later, Quinby reawakened interest in the subject by his report of several interesting cases in which the ureter had been reimplanted into the renal pelvis. Some of these cases he had traced for as long as eight years subsequent to operation. Three years ago, Braasch and I began a series of studies in a group of cases in which I had successfully resected the hydronephrotic renal pelvis, and reports of these cases with preoperative and postoperative studies of renal function and pyelographic studies were presented last year. Braasch, in 1912, reported three cases in which heminephrectomy was successfully performed by W. J. Mayo. Hugh Young and Edwin Davis, in 1917, called attention to the fact that these three cases were probably the first successful ones in the United States. At that time they were able to find in the literature only twenty-six cases in which heminephrectomy had been done for duplication of the renal pelvis. They stated that, in sixteen of these cases, half of the kidney was normal and the conservative operation of heminephrectomy could have been done rather than nephrectomy, which had been done. McKim and Smith, in 1924, reviewed from the literature a series of 120 cases of solitary cyst of the kidney, including three of their own. In thirty-four of the series resection of the cyst was performed, with recovery in thirty-one cases. I want to emphasize again, in the treatment of multiple calculi in the kidney, that the decision as to whether the kidney should be removed or whether the conservative operation of pelviolithotomy should be done should rest not so much on the technical difficulties as on the appearance of the kidney, its size, the relative amount of renal parenchyma present, and the degree of hydronephrosis and the degree of dilatation of the calices, if any. In other words, the decision should rest on the ability of the kidney to function and drain properly.

THE INCIDENCE OF RECURRENT RESPIRATORY INFECTIONS IN CHILDHOOD *

C. C. McLEAN, M.D.
BIRMINGHAM, ALA.

Respiratory infections comprise one of the great problems of the day from both an economic and a social standpoint. Sydenstricker[1] of the United States Public Health Service found that more than half of the total deaths were due to respiratory diseases, notwithstanding the fact that the ratio of respiratory illnesses to deaths from respiratory causes was 300 to 1. These figures are almost identical with the statistics of the United States Army.[2]

Respiratory infections are responsible for more than half the time lost by the wage earner due to illness. The percentage of children who lose time from school as the result of respiratory infections is probably higher than that of the wage earner. I feel that anything, no matter how small, that might help directly or indirectly to a better understanding of the clinical manifestations of the disease, in the hope that in the future it might throw some light on the solution of this great problem,[3] is well worth time and consideration.

Experimental studies and investigations in respiratory infections are being made largely along a bacteriologic line.[4] Clinical observations have been confined principally to groups of individuals, this information being obtained largely by questionnaires. Townsend,[5] Smiley [6] and Barrow [7] have reviewed the literature and have done much work. From investigations among college students, it was found that repeated colds each season were as prevalent in one section of the country as another.

Smiley [6] of Cornell University states that "smoking, exercise, cold baths, hours of sleep, draft over beds, kind of underwear, kind of footwear worn in wet weather, perspiration after exertion, constipation, exposure to dust or gas, mouth breathing, nose and throat operations and family history in regard to 'colds' had little or no apparent effect on the susceptibility of the individual to repeated attacks of respiratory infections."

Barrow [7] of Stanford University states that: "1. The incidence of colds is not markedly influenced by the various systems of heating used in the studies and living rooms of the students. 2. Whether the students use sleeping porches, well ventilated bedrooms or poorly ventilated bedrooms for sleeping purposes does not materially affect the individual's susceptibility to respiratory infections."

Apparently little or no effort is being made toward a better understanding of the clinical manifestations of the diseases by the study of the conditions in individual patients in early childhood.

Every physician, probably, has been impressed with the large number of children who have two or more distinct respiratory infections during the fall and winter months.

In 582 patients with respiratory infections seen in private practice from Sept. 1, 1928, to June 1, 1929, accurate records were made, with especial reference to recurrent infections. For comparison, 381 children with respiratory infections were observed from Sept. 1, 1929, to May 1, 1930.

RECURRENT INFECTIONS

Children are not considered as having a recurrent infection except those who were free from symptoms for at least three weeks and had previously that season been seen and treated with the primary condition.

The time elapsing between the primary and recurrent infections is calculated from the date of the last visit of the old illness to the date of the first visit of the new illness.

Many of the children in the series had other infections and were treated in the homes by their mothers or by other physicians, but owing to the inaccuracy of histories obtained from the parents, no infections are included in the series except those in children who were seen professionally.

The percentage of recurrent respiratory infections, according to ages, of the 582 children to be reported, as compared with 381 cases observed from Sept. 1, 1929, to May 1, 1930, and 361 cases reported in 1928,[8] shows that recurrent infections are common in patients of all ages, the age of the child apparently having little influence on the number of recurrent infections. Recurrent infections are as prevalent in one year as in another and occur in about the same percentage each year. Of the 582 patients with respiratory infections observed from Sept. 1, 1928, to June 1, 1929, 241, or 41.7 per cent, had one or more recurrent respiratory infections.

Of 381 patients with respiratory infections observed from Sept. 1, 1929, to May 1, 1930, 142, or 37.2 per cent, had one or more recurrent respiratory infections.

WEATHER CONDITIONS

An attempt was made to see what effect weather conditions had on the number of primary and recurrent respiratory infections. Each month from September to June was divided into four weeks. The actual temperature, sunshine and rainfall each week was compared with the normal or average for the same period, and the number of primary and recurrent respiratory infections seen that week were considered in relation to the weather conditions. Apparently, weather conditions had no effect on the number of either the primary or the recurrent respiratory infections.

During the month of December, in which the peak in the epidemic was reached, 30 per cent of the total number of respiratory infections were seen and the weather conditions were apparently ideal. The temperature averaged 0.4 degree above normal. There was 13 per cent more sunshine than the average. During the month there were only five days in which it rained, and this includes the days in which there was as much as 0.01 inch of rainfall.

TONSILLECTOMY AND ADENOIDECTOMY

Recurrent respiratory infections were prevalent in both the patients who had had the tonsils and adenoids removed and in those who had not had the operation. Of the children under 3 years of age with recurrent respiratory infections, only 6 per cent had had the tonsils and adenoids removed. Of the children over 3 years of age with recurrent respiratory infections, 49 per cent had had the operation. The variation in the percentage of the recurrent incidence, according to ages, in children who had had tonsillectomy and adenoidectomy can be explained by the fact that many of the children over 3 years of age have had the operation, while very few of the younger children have had the tonsils and adenoids removed.

TABLE 2.—*Percentage of Recurrent Respiratory Infections According to Age*

Sept. 1, 1928–June 1, 1929

Age in Years	Number Patients	Per Cent with Recurrent Respiratory Infection
0 to 1	90	48.8
1 to 2	115	51.3
2 to 3	83	35.2
Over 3	294	35.6
Total	582	41.7

Table 3 is the most interesting table of the series, showing a marked variation in the monthly percentage increase in the total number of primary cases, while the monthly percentage of the recurrent infections in primary cases shows little variation.

During the months of December, January and February, 353, 60 per cent of the total number of primary cases, were seen. The monthly percentage of increase varied from 7.1 per cent to 55.7 per cent. During this period, the variation in the monthly percentage of recurrent infections in the primary cases was 1.2 per cent, though more than half the total number of recurrent infections were seen.

TABLE 3.—*Monthly Percentage Increase in Total Number of Primary Respiratory Infections, as Compared with Monthly Percentage of All Recurrences in Primary Cases*

September 1, 1928–June 1, 1929

Months	Number Primary Infections per Month	Number Recurrent Infections per Month	Monthly Percentage Increase of Total Number of Primary Cases (Including Current Month)	Monthly Percentage of Recurrences of All Primary Cases
Sept.	31	1	....	....
Oct.	56	7	64.3	8.0
Nov.	94	18	52.0	9.9
Dec.*	228	58	55.7†	14.1‡
Jan.	87	64	17.5	12.9
Feb.	38	73	7.1	13.6
Mar.	24	57	4.3	10.2
Apr.	13	46	2.2	8.0
May	11	27	1.8	4.6
Total....	582	351		

* In comparing the monthly percentage increase of the total number of primary cases with the monthly percentage of recurrent infections of the total primary cases, the current month must be included, as a certain number of the recurrent infections are recurrences of the primary cases of the current month.

† The monthly percentage increase of the total primary cases for the month of December, 55.7, is obtained by dividing 228 by 409 (the sum of 31, 56, 94 and 228).

‡ The monthly percentage of recurrences of total primary cases for the month of December, 14.1, is obtained by dividing 58 by 409.

During the months of September, October, November and December there is a marked increase each month in the number of both the primary and the recurrent respiratory infections. During the month of December the peak of the epidemic is reached. From December to June each month shows a sharp reduction in the number of primary cases, but this is not true with the recurrent infections.

In the month of December, 228, or 39.1 per cent, of the total number of primary cases were seen. There were 58 recurrent infections.

In January, 87 primary and 64 recurrent infections were seen. There were 141, or 62 per cent fewer primary cases than in December. There was an increase of 6, or 10 per cent in the number of recurrent infections, notwithstanding the 62 per cent reduction in the number of primary cases.

In February, 38 primary infections and 73 recurrent infections were seen. There were 49, or 56 per cent, fewer primary cases than in the preceding month. There was an increase of 9, or 14 per cent, in the number of recurrent infections.

From these observations, it seems that contact with other individuals who have the disease has little or no influence on the number of recurrent respiratory infections and a marked influence on the number of primary respiratory infections.

The chart shows the weekly incidence of all the recurrent respiratory infections in the primary cases. The peaks in the weekly incidence of the total recurrent infections are the fourth, seventh, thirteenth, fifteenth, eighteenth and twenty-first weeks.[9]

---

[9] When it is stated that a recurrent infection occurred in four weeks, it means that the child's illness with the second infection began some time between the third and the fourth week from the date of the last visit of the old illness to the date of the first visit of the new illness. If the recurrence is five weeks, the illness began some time between the fourth and the fifth week from the date of the last visit of the old illness to the date of the first visit of the new illness and thus according to the week stated.

The recurrent infections in the younger children reach their peak a week earlier at the seventh and thirteenth weeks. At the fifteenth week the older children do not show a peak. At the fourth, eighteenth and twenty-first weeks, the peaks are the same in children of all ages.

The variation in the peaks of the seventh and thirteenth weeks might be due to one of two things: the younger children are sicker and the physician is called earlier, or the parents' interests are more centered in the younger children.

When the inaccuracy of the methods of estimating the time between the end of the old illness and the beginning of the new is considered, the consistency in the peaks of the recurrent infections is the more remarkable and suggests that a respiratory infection is a periodic recurrent disease.

OTHER OBSERVATIONS

The upper respiratory types of infection predominated, the larger number of cases being of a nasopharyngeal and tonsillar type.

One hundred and three patients had definite ear involvements. Sixteen ear drums discharged spontaneously a blood-stained serofibrinous exudate, smears showing few pus cells and many organisms. In the majority of cases, the ears were dry at the end of forty-eight hours. Eighteen patients had one or both ears punctured. No ear discharged pus longer than three weeks. The majority were dry at the end of a week and in none of the cases were there signs or symptoms of a mastoid involvement.

Clinically, the nonirrigated ears did better; the discharge was of a shorter duration and less profuse than in the cases in which irrigation was used.

In forty-three cases spasmodic croup was one of the most pronounced symptoms.

TABLE 4.—*Percentages from Sept. 1, 1929, to May 1, 1930* *

* To be compared with table 3. The same consistency in the monthly percentage of recurrent infections in the 381 patients observed from Sept. 1, 1929, to May 1, 1930, as in the 582 cases reported is shown even though there was no epidemic this season.

There were twenty-two cases of cervical adenitis, many of them being characterized by high and widely fluctuating temperature of a two and three weeks' duration.

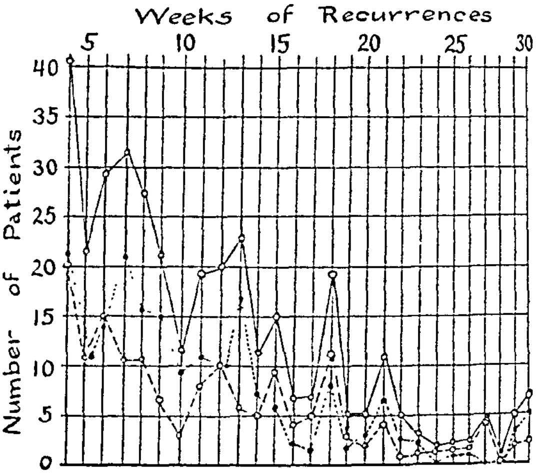
Ulcerative stomatitis was noted in ten cases.

There were 120 patients in whom bronchitis was the most pronounced symptom. Of these, forty-seven were of an asthmatic type.

There were fifteen cases of lobar pneumonia; of these, four developed empyema. The ages of the patients with empyema were 5, 6, 7 and 8 years. Cultures and smears of two cases showed a pneumococcus and two a hemolytic streptococcus, one of the hemolytic streptococcus patients having a double empyema. The four patients were operated on under local anesthesia and made a good recovery.

In sixty-five of the cases, nausea, vomiting, dehydration, pain in the abdomen or diarrhea were among the most pronounced symptoms.

There were two deaths: One child, aged 12 months, had a congenital malformation of the heart, developed a bronchopneumonia and died in twenty-four hours.



Weekly recurrent incidence of all the recurrences in the primary respiratory infections: solid line, total recurrences; dotted line, recurrences in children over 2 years of age; broken line, recurrences in children under 2 years of age.

The other case was rather interesting: A boy, aged 2 years, had a sudden onset of nausea and vomiting. The temperature was 106 F. He had a slight bronchitis. The white blood count was 20,500; neutrophils, 88 per cent. The child was thought to have an influenzal infection with a probable pneumonia. At the end of forty-eight hours the right elbow and right knee were swollen, inflamed and extremely tender. There were some slight cerebral symptoms. A blood culture was made. The next day the condition was worse; cerebral symptoms were more marked. A spinal puncture was done; cloudy fluid under pressure was obtained; smears and cultures showed a small gram-negative bacillus with all the cultural characteristics of Pfeiffer's bacillus, a blood culture showing the same organisms.

SUMMARY

1. Of 582 children with respiratory infections observed from Sept. 1, 1928, to June 1, 1929, 241, or 41.7 per cent, had one or more recurrent infections.

2. Weather conditions apparently had little or no effect on the number of primary or recurrent respiratory infections.

3. The recurrent infections were apparently as common in the patient who had had tonsillectomy and adenoidectomy as those who had not had the operation.

4. The monthly percentage increase of the total number of primary cases showed a marked variation, while the monthly percentage of recurrences in primary cases showed little variation.

5. Contact with individuals who had the disease seemed to have a marked influence on the number of primary infections.

6. Apparently, contact with individuals with the disease had little or no effect on the number of recurrent infections.

CONCLUSION

The consistency in the periodic recurrent incidence in respiratory infections, as observed over an eight year period, is more than suggestive of a periodic recurrent disease.

2012 South Tenth Avenue.

ABSTRACT OF DISCUSSION

Dr. Franklin P. Gengenbach, Denver: There seems to be an increasing number of primary colds in the winter up to a certain point, which in Birmingham reaches its peak about December. Dr. McLean has arbitrarily accepted for his statistics only cases he has seen himself and recurring infections in which there has been an interval of at least three weeks from the last visit he paid in the previous infection and the first visit in the infection following. It might have been perhaps more valuable to know the actual number of cold infections that the child had during the winter. It is quite evident from these figures that most of the colds come at a time when there is the greatest difference between inside and outside temperatures. There is no question that the tendency to colds is increased by the overheating of houses and apartments. As people come in contact with the low outside temperatures, either through the open windows or when they go outdoors, the tendency to colds is increased. An interesting observation was that in the children of older age, 2 or 3 years or older, there were practically as many colds and other respiratory infections in those who had their tonsils out as in those who had their tonsils intact. This again serves as a warning that when physicians advise having tonsils and adenoids removed they must not promise their patients too much. I am sure that too many men advise tonsillectomy simply on the basis of recurrent colds and without distinct evidence of infection of the tonsils. My own custom is practically never to advise tonsillectomy unless there is a persistent enlargement of the cervical glands that drain the tonsils. These recurrent colds coming after tonsillectomy involve the lymphoid tissue in the pharynx, particularly behind the posterior pillars, and often it becomes hypertrophied and cryptic. That is why there are just as many colds and sore throats and often just as many cases of cervical adenitis in those in whom the tonsils have been removed. That does not mean that no advantage is secured in having the tonsils and adenoids removed. My own observation is that, while these children may appear to get as many respiratory infections, they throw them off much more quickly and are much less likely to have severe complications.

Dr. W. G. Smillie, Boston: Field studies have been made of the effect of environmental influences on colds in various parts of the world. The first was in Alabama, in an isolated community. The second was along the Labrador Coast, up the Northwest River about a hundred miles, in a community of Indians and traders, during the summer of 1928. The following year a study was made on an isolated island of the West Indies. The next field study will probably be conducted in Spitzbergen, under the arctic circle. The studies show that colds are less prevalent and much less severe in the tropics than in the temperate zones. The seasonal incidence of colds shows a very low rate in the summer months, a peak in October, with a fall and then a distinct peak in January or February, with scattered cases through the late spring. This indicates some relationship between changes in atmospheric temperature and colds. Even in the tropics, where the temperature varies only a few degrees from winter to summer, one finds the usual incidence curve noted in the temperate zones, in which temperature changes are much more abrupt. The relationship of rainfall, maximum and minimum temperature, barometric pressure and other factors with the incidence of colds has been studied without finding any correlation. So far as can be told from the bacteriologic observations, no known organisms are related to the incidence of epidemics of colds. There seems to be a definite relationship, however, between certain micro-organisms and the occurrence of complications of colds, colds of long standing, and recurrent colds. Pneumococci and influenza bacilli seem to be the chief offenders. The striking thing about the incidence of the disease in the tropics is that, although people have colds, these colds are very mild and are not complicated by middle ear disturbances, pneumonia, bronchitis or sinusitis.

Clinical Notes, Suggestions and New Instruments

TRAUMATIC PERFORATION OF ESOPHAGUS WITH MEDIASTINITIS; OPERATION AND RECOVERY

Harry Meyersburg, M.D., Brooklyn

A white woman, aged 60, with a negative past history, was admitted, Oct. 17, 1928, seven hours after she had swallowed some bottled horseradish containing particles of glass. She immediately felt a sharp pain in her throat, followed by pain in the epigastrium and right shoulder. She attempted to induce vomiting with her finger and brought up some bloody food particles. She came to the hospital because of an increase of pain in the throat. She had tenderness over the xiphoid cartilage and between the tenth and twelfth vertebrae. There was no abdominal tenderness or spasm.

Indirect laryngoscopy was negative. A roentgenogram was taken following a barium meal and revealed a slightly irregularly outlined opaque mass at the level of the clavicles, not at all typical of a diverticulum and probably an extravasation of barium into the tissue about the esophagus; there was an irregular area of increased density in this region which might possibly be a foreign body coated with barium. Esophagoscopy was performed and revealed a deep abrasion at the mouth of the esophagus at the level of the cricopharyngeus, and a sausage skin covered with barium was removed. The temperature, pulse and respiration were normal. Blood examination revealed white blood cells, 12,400; polymorphonuclears, 82 per cent, and hemoglobin, 76 per cent. The blood pressure was 150 systolic and 78 diastolic. Urinalysis showed an occasional cast and a trace of albumin.

The next day, October 18, she made the same complaint and her general condition appeared to be worse with a temperature of 99.4 F., pulse 100 and respirations 20. A roentgenogram on this day showed a greater retention of barium at the level of the clavicles. October 19, the patient's condition was poor; she was cyanotic and having labored breathing. There was some crepitation of the neck tissues and an examination of the chest suggested an extension to the right base. The medical advice was to permit the patient to have complete rest with no intervention. However, esophagoscopy was performed the same day and forceps were carried through the lacerated fibrinous area located to the right on the posterior wall at the level of the cricopharyngeus, with the liberation of a foul creamy pus under pressure.

External drainage was immediately decided on and local anesthesia was used. An incision was made along the anterior border of the right sternomastoid, and the esophagus was reached by dissecting through the planes of cleavage. In the region of the cricoid cartilage just posterior to the esophagus in the midline, foul pus was encountered which was found to extend well into the superior mediastinum. The foot of the table was elevated and two iodoform strips were placed as far as possible into the mediastinum and two along the upper portion of the esophagus. The wound was closed loosely with a few sutures. A Rehfuss tube was then introduced under direct vision and the patient was put to bed feeling more comfortable.

A roentgenogram then showed evidence of pleuritis with effusion in the right side of the chest and the mediastinum. A culture of the pus did not show any gas bacilli. The patient expelled the Rehfuss tube the same evening and was not fed by mouth for three days, after which she was started with fluids by mouth. The following ten days after operation the temperature varied between 98.6 and 102 F. daily, after which it remained normal. She received a therapeutic x-ray exposure for mediastinitis, October 20, and a roentgenogram, October 25, showed an increase of mediastinal shadow with some pneumonic involvement at both bases. Esophagoscopy, October 29, revealed a healed laceration. The patient was up and about, November 5,

No patient should be permitted or told merely to exercise his arm. It is the duty of every physician prescribing exercise to give definite directions as to the amount and kind. In the case of the patient with average intelligence, the anatomy of the part to be exercised and the reasons for the exercises should be explained to him. To those who understand considerable human anatomy, definite instructions should be given.

In giving directions for exercises it should be impressed on the patient that although heat, massage and electrical stimulation are used for his weak muscles, these are only to increase the circulation and nothing will increase muscle power but active exercise, which requires volitional effort on his part. To insure the proper regimen of treatment, definite written instructions for exercises should be given the patient and proper occupational therapy prescribed.

Muscle reeducation is that form of therapeutic exercise given to muscles in which the neuromuscular coordination has in some way become partially destroyed. The reflex arc has become involved, making it impossible for the muscles to move by means of the reflex mechanism. As a result, coordinated movement is lost. To reeducate muscles under such conditions two things are necessary: first, to reestablish a better coordination between the remaining nerve fibers and cells supplying the affected muscle, and, second, to secure the contraction of the desired muscle, however feeble.[5]

Mackenzie says that if a muscle is weakened or paralyzed, whether from injury of muscle, nerve or central cell, it is rested when its opponent is in a state of relaxation or elongation beyond the state normally regarded as necessary to produce a condition of equilibrium with its opponent. This is the zero position. Reeducation of a paralyzed muscle begins at zero and is the encouragement of voluntary muscle movements within functional limitations. The amount of work at this minimum may be slight, but it is the maximum function of the muscle at this time, and the muscle may soon become exhausted.[6]

Curative occupational therapy is a form of therapeutic exercise which requires a series of specific voluntary movements, initiated by the patient, which form component parts of a more complex and coordinated movement. This exercise is designed for the express purpose of securing definite end-results and is a direct incentive for sustained effort.

The ordinary physical treatment given to a patient lasts, at the most, only an hour. The mechanical exercises given have certain definite limitations. The human body is more than a machine, and the formal repetition of a movement either with or without an apparatus is not of maximum therapeutic value in increasing the amount of movement in a stiff joint or as an integral part of a large coordinated movement. There is no pschologic stimulant for personal initiative, or for sustained effort. The patient can be told to exercise, but unless occupational therapy is used there is no incentive and interest provided to continue the exercise.

In physical therapy the patient's attention is focused on the injury while in occupational therapy his interest is in the work.

THERAPEUTIC EXERCISE FOR THE SHOULDER JOINT

The shoulder joint, anatomically considered, is peculiarly liable to injury. It is a known experimental fact that, when movement of a joint is stopped and the part immobilized, muscular atrophy takes place within two hours. Therefore, in view of the importance of the musculature of the shoulder joint relative to injury, it may be stated that one of the most essential elements in the treatment is early exercise because the restoration of function of the shoulder is dependent to a large extent on proper muscle action. Physical therapy plays an important part in the restoration of its function. Of the forms of physical therapy used, therapeutic exercise stands out most prominently in assisting in the more rapid restoration of normal function.

It is well to know just what structures are involved. For the purpose of more easily understanding them, they can be divided into periarticular and intra-articular, the former representing all those without the capsule and the latter those within the capsule. It is necessary not only to know what parts are injured but also to determine the extent of injury. These may be a simple strain of the muscles due to overuse or a complicated fracture dislocation with extensive involvement of all structures both periarticular and intra-articular. Severe injuries produce a marked extravasation of coagulable fluid into the surrounding tissues which results in the formation of fibrous adhesions. Since the muscles of the shoulder joint hold it in its normal position, an injury to them becomes a serious matter. In addition, the intra-articular surfaces may be injured, as for example a fracture into the joint causing damage to the synovial membrane and cartilage. This, again, produces adhesions within the joint and increased synovial fluid. It is this destruction of tissue, the extravasation of fluid, and the subsequent formation of adhesions that result in muscle spasm and limitation of movement. It is, therefore, toward the restoration of their function that the treatment is aimed.

Mackenzie, in his classification of muscles moving the humerus, points out the important fact that the abductors of the shoulder joint are the relatively weak deltoid and the supraspinatus and that the adductor is the strong pectoralis major. The external rotators are the weak infraspinatus and the teres minor, while the internal rotators are the strong latissmus dorsi and the subscapularis. With this in mind, it is well in shoulder joint injuries requiring prolonged immobilization to put the arm in abduction and external rotation. This can be done in an aeroplane splint or in a plaster cast with the cover of the cast cut so that it can be raised. The muscle origin, insertion and action determine the splinting. Therefore, if after a shoulder joint injury the arm is bound to the side, the anatomy, physiology, and pathology are ignored. Too frequently, this position is maintained for three weeks or more with the strong muscles shortened and the weak ones stretched, and in addition the weight of the upper limb dragging on the weakened deltoid supplied by an injured nerve.

In intra-articular involvement a cardinal point brought out by Dr. Lovett [5] is that the secretion of the synovial membrane is stimulated by motion of the joint and diminished by rest. With an injury to the synovial membrane, the absorption power and circulation in the surrounding area is seriously affected. Therefore, if the joint is moved too soon with such a blockage, the only result obtained will be an increase in fluid within the joint cavity producing more pain and increased pathologic changes. Such a joint requires rest to permit the excessive fluid to be absorbed. With a complicating fracture into the joint, it can be readily seen that active movement must be delayed and that carefully regulated passive motion must be instituted to prevent adhesions from forming. Active exercise should be encouraged only when the bones have had sufficient time in which to unite. In fractures about the head of the humerus the same principle holds true, and when passive motion is used the fracture should be closely splinted and well supported.

[5] Jones and Lovett: Orthopedic Surgery, New York, William Wood & Co., 1929, 2nd Edition.

[6] Mackenzie: The Action of Muscles, ed. 2, New York, Paul B. Hoeber, Inc., 1930.

Other structures that may be injured in the periarticular portion of the shoulder other than the ligaments, tendons, muscles, blood vessels and nerves are the bursae, the chief of which is the subacromial or subdeltoid, located between the under surface of the deltoid muscle and the outer surface of the capsule. Because of its close association to the joint, it is peculiarly liable to injury and requires special treatment.

Before prescribing therapeutic exercise for shoulder joint conditions, the underlying pathologic condition must be understood. This means that a thorough examination and diagnosis must be made. A careful inspection and palpation of this region interpreting the limitation of motion in terms of muscle origin, insertion and action will often prevent the misinterpretation of a roentgenogram. There are no injuries about the body in which a knowledge of muscle action is more important than in the diagnosis and treatment of shoulder injuries. A joint must be considered physiologically as a whole with no one component being injured without having an effect on the whole mechanism. It is necessary to understand the various movements of the shoulder joint and the extent of their range. It is well in this connection to compare the movements with the sound side. Beevor's classification is given herewith for the normal shoulder joint.[5] These movements, summarized, are flexion, extension, hyperextension, abduction, adduction, horizontal adduction and abduction, and internal and external rotation. Each of the movements, together with the number of degrees possible, is given for the normal shoulder. It is to be understood that different individuals may differ with regard to extent of movement and, therefore, it is always necessary to compare the injured side with the sound one.

Flexion of the humerus: Place the arm at the side and raise it to front horizontal, and then above the head until vertical. This is the anteroposterior plane and produces an arc of 180 degrees. This is the normal range for flexion.

Extension of the humerus: With the arm above the head in extreme flexion, move it downward and forward to its original position at the side. This brings the arm through the same anteroposterior plane and the range is through the same 180 degree arc.

Hyperextension of the humerus: With the arm at the side, move it backward as far as it will go through the same plane. The average degree of movement for this distance is 45 degrees.

Abduction of the humerus: With the arm at the side, carry it laterally to a side horizontal position at a distance of 90 degrees. At this point the movement in the shoulder joint is stopped by the tension of the capsule. From then on the movement is carried out by the scapula until it arrives in a vertical position above the head, covering a distance of 180 degrees.

Adduction of the humerus: The arm is again carried down through the same lateral plane, through the same number of degrees to the side of the body.

Horizontal adduction and abduction: The arm is placed in side horizontal position and the arm is then brought forward to a front horizontal position. This is termed adduction and the arc range is 90 degrees, which is much extended by scapular movement. Abduction is just the opposite of adduction and through the same plane and a 90 degree range.

Internal and external rotation: The arm is abducted to a horizontal position, the elbow flexed and the forearm at right angles, which brings the shoulder joint in a position of external rotation. Bringing the forearm forward and downward produces internal rotation. The arc is 90 degrees in this plane. With the arm in partial abduction and the forearm extended, the degree of rotation increases to 135 degrees.

It is important to note here that the scapula takes part in practically all movements. The determination of the actual range of shoulder movements is difficult and inaccurate. As the mobility of the scapula is highly variable, all angular movements in and about the shoulder joint must be necessarily approximate.

Each of these movements should be done and the number of degrees measured and properly recorded. In order to obtain some idea of the degree of disability, a record of the progress should be made at definite intervals of time. If the movements are found to be limited in all directions, there is in all probability an arthritis. If, however, there is limitation in only a few directions, it is probably a periarticular injury and limited to the soft parts. If the second examination shows no increase in range of movement there may be complications and another thorough examination should be made.

If the range steadily increases even though there is some occasional pain, progress is being made in the right direction.

ROUTINE MANAGEMENT OF A SPRAIN OF THE SHOULDER JOINT

The first objectives are to control the hemorrhage, to prevent the overstretching of the weaker and injured muscles and the contracture of the stronger antagonists, and to encourage healing.[7]

The patient is placed on a padded table in the supine position with the arm resting on a smooth rectangular board. The arm is carefully moved to a horizontal position and the forearm flexed and in external rotation. The whole region is then covered smoothly with cotton or sheet wadding, and over this a firm spica is applied. An aeroplane splint is then put on with the arm in abduction and external rotation, the position of greatest physiologic rest. Within three hours the spica is removed and in its place an elastic ace bandage is put on. It is well to apply the ace bandage during the early stages of treatment for the reason that the blood vessels are allowed to relax and in this way a fresh blood supply is brought to the part, and the reapplication assists in squeezing out the extravasated débris. By this method the hemorrhage has been controlled and the weaker muscles have been placed in a state of physiologic rest, and by so doing the stronger antagonists have been prevented from forming contractures. This position naturally favors healing, by placing the injured muscles in a relaxed position.

The second objectives are to prevent stiffness due to the formation of adhesions from immobilization, to restore the circulation to normal, to rid the part of extravasated fluid, and to prevent the atrophy of the muscle.

---

[7] Whitelocke, R. H. A.: Sprains and Allied Injuries of Joints, Oxford Medical Publications, 1930.

Just as soon as the acute symptoms have subsided and healing has progressed, it is time to start therapeutic exercise in conjunction with other preliminary physical therapy measures. At the end of from twenty-four to seventy-two hours, the acute symptoms in most cases have abated. The patient is placed in a position of complete repose, lying on a padded table in the supine position, with the injured arm on a smooth rectangular board which has been powdered. At this point it is well to be certain that the patient is completely relaxed. For this reason heat and a light stroking massage are used,[1] just before the aeroplane splint is removed. The influence of and use of external heat is well set forth in a report by the Council on Physical Therapy of the American Medical Association.[8]

The tissues are put in a condition to benefit by massage and mobilization. Dry heat is the form used and may be given with a radiant light lamp for a period of from half an hour to an hour. This is followed by very light stroking massage, which helps materially in giving relaxation.

With complete relaxation, passive movement is now started. The patient is properly grasped by the operator with the arm in the same position as it was in the aeroplane splint. One hand of the operator firmly takes hold of the arm just above the elbow and the other grasps the hand. The arm is first brought through just one or two movements in the horizontal plane, the operator constantly on the alert for muscle spasm. It must be borne in mind in using passive movement that it is much better to bring the arm through to its capacity for movement. When muscle spasm occurs one should stop and hold at that point for a few moments, say to the count of five.

The joint range having been increased by means of passive movement, the way is prepared for active exercise. The first forms of active exercise used are of the assistive and free types. With the arm in the same position as for passive movement and resting on the same smooth, well powdered, rectangular board, the operator adducts the arm to the range previously acquired by passive exercise. The patient then abducts it to side horizontal positions. Fibrillation of the deltoid may occur and, if such is the case, assistance is given. Here the operator gently produces light pressure upward at the elbow and helps the deltoid to contract. As the movement gains power, the patient completes the arc without assistance and this is termed free movement.

Each day the amount of assistance is lessened and true free movement is instituted. By so doing the normal neuromuscular response is called into play and with it increase in the range and power of muscular movement. In the same plane, light resistive exercise may be applied by gentle attempts to stop abduction. Thus there is gradual progression from assistive exercise through to the resistive type.

Resistive exercise can now be started in earnest, and the operator can work in all planes, first assisting and later adding resistance. At this point the patient can gradually be raised to a sitting position, and by so doing the resistance of gravity is added. Assistive exercise may have to be combined with the resistive as the patient is raised, assistance being given in the first and last thirds of the arc of movement.

The range and strength of the muscles of the shoulder have been increased now in all planes because of the carefully regulated assistive, free and resistive exercise. The operator's work is now combined with a series of exercises which the patient is taught for home use. The following are suggested exercises. The particular exercises to be used should be underlined. The number of times each movement is to be used must be indicated.

HOME EXERCISES FOR THE SHOULDER

1. While the shoulder is in the splint, contract deltoid and then relax without moving the shoulder joint or using other muscles. This is to be done as often as the patient feels disposed during the day. Stop just as soon as the muscle tires.

2. Lying on the back, the arm and shoulder on a powdered cardboard, in the same position as in the splint, forearm supported, the operator adducts the arm a few degrees, and the patient brings it to the original position. Increase the range of motion.

3. Same position as 2, revolve the forearm until the back of the hand touches the table.

4. Same position as 2, move the arm across the body so that the hand touches the opposite shoulder.

5. Lying on the back with the arm at the side and the forearm flexed at right angles, bring the arm forward and up and return.

6. Lying, face down, the hands in back of the neck: (*a*) Raise both elbows and the head from the table without raising the body. (*b*) Raise the elbows with some one putting pressure on the elbows.

7. Standing, with the arms at the side, swing to the front, horizontal and then above the head and return.

8. Standing, with the hands clasped behind the back, fingers interlocked, the palms facing up, turn the palms in and down, and extend the arms to the rear at the same time.

9. Standing, with the hands at the side, swing the arm to side horizontal and then above the head and return.

10. Standing, with the arms in the front horizontal position, swing to the side horizontal position, to front horizontal position and return to original position.

11. Shoulder shrug.

12. Standing with arms in side horizontal position, move arms in small and large circles and in both directions.

13. With the arms in side horizontal position, rotate arms so palms are alternately up and down.

As the strength of the patient increases, more resistance can be added with books or dumb-bells, starting with light weight and increasing the weight as the capacity of the patient increases.

The pulley weights can be used to increase the resistance.

Curative occupational therapy for shoulder cases should be definitely prescribed. It can be used in any place with a little ingenuity. For instance, "braid weave" rug weaving may be used. No shuttle or beater is necessary and no sewing is required. The method does not require a complicated loom. The weaving, partaking somewhat of basketry, is fascinating and simple.

The loom can be home made. It is 30 by 50 inches, made of 1½ by three-fourths inch wood. A series of one-fourth inch slits at the top and bottom half an inch apart accommodate the warp. Along the inside a half-inch from the inside edge of the loom are brass one-fourth inch curtain rods to hold the weaving in perfect alinement and to insure a straight edge to the rug. The weaving is done with rags, which may be colored and a pattern followed. These looms may be made in various sizes and placed in various positions to conform with the patient's strength and to the joint movements required. By placing the loom high on a wall shoulder flexion, external rotation and abduction of the shoulder may be obtained. These looms may of course be purchased complete. After proper instruction the patient can use this loom at home.

CONCLUSIONS

In shoulder joint cases, therapeutic exercise is used according to the principles previously mentioned, starting with passive movement, progressing to assistive exercise and using muscle training if necessary and then using free and resistive exercises, which include occupational therapy.

The Chemical Laboratory

The following is a report of the American Medical Association Chemical Laboratory. Paul Nicholas Leech, Director.

ALBUTESTA

A Proprietary Reagent

Albutesta is a coined name for a chemical reagent to detect albumin in urine. The makers of this product, Menley & James of London, England, and also of New York, have been noted in the past for unscientific proprietaries. For instance, at very frequent intervals physicians receive through the mail free samples of "Iodex," a black ointment sent out in small, circular, aluminum boxes. A few years ago a claim was made by the firm that this ointment contained 5 per cent of free iodine, minus the objectionable features that go with free iodine. Work done in the A. M. A. Chemical Laboratory showed, first, that the product did not contain iodine in the free form but in the combined form and, secondly, that there was less than 5 per cent of total iodine present (The Journal, June 19, 1915, p. 2085). Again in 1919 the laboratory examined market specimens of "Iodex" and found, as before, a deficiency in iodine content, about three fifths of the amount claimed. It was pointed out that it was impossible to have free iodine present in sufficient quantities to be therapeutically efficient and not get skin stains or irritation. Later the laboratory analyzed the companion proprietary, "Liquid Iodex," which was claimed to be a nonirritant preparation of iodine and to contain "free iodine." On examination at that time this product was found to contain only about 0.16 per cent of free iodine and about three fifths of the total iodine claimed.

Now another proprietary of this firm is extensively advertised to physicians, Albutesta, a new test for albumin. Some of the claims made for the preparation are as follows:

"Dependable". "Non-poisonous" "Does not stain the hands" "Just a few drops in the test tube reacts immediately. No boiling, no acid. Takes but one-quarter the time of the older tests. Its dependability and simplicity suggests home testing in maternity cases." The price for this so-called new test for albumin is $1.

Original packages of Albutesta were purchased by the A. M. A. Chemical Laboratory and subjected to examination. In each trade package there was a one ounce flint bottle containing 33 cc. (approximately 1 fluidounce) of a colorless liquid, a crudely constructed medicine dropper and a small test tube. The solution was odorless and possessed a distinct sour taste. The reaction of the mixture to litmus was distinctly acid.

No information concerning the composition of Albutesta[1] appeared on the trade package. No circular accompanied the product.

Qualitative tests indicated the presence of an organic acid, indicative of sulphosalicylic acid.

The results of the quantitative determinations were as follows:

Specific gravity at 25 C.	1.078	
Total solids (residue on evaporation)	17.55	per cent
Ash	0.02	per cent
Sulphosalicylic acid (by titration)	16.99	per cent

It appears, therefore, that Albutesta is simply a proprietary name for a preparation having the essential qualities of a 20 per cent aqueous solution of sulphosalicylic acid. Albutesta sells for $1. The cost of ingredients of 1 ounce of sulphosalicylic acid solution, 20 per cent, is about 5 cents.

In any chemical analysis it is almost axiomatic that the analyst must know the composition or definite attributes of the reagent he is using if he expects to be at all scientific. It is, therefore, stupid to make chemical tests, on which clinical interpretations are to be made, with a reagent the composition of which is not known and under conditions in which there may be interfering substances. The limitations as well as advantages of any reagent should be known. If one desires to use the sulphosalicylic acid test for albumin he should use a solution of known strength and composition.

Roch[2] was the first to use the substance as a precipitant for protein in the urine and at that time sulphosalicylic acid impressed many workers, primarily MacWilliam,[3] who demonstrated its differential value. Witthaus[4] some years later in his manual described the use of Roch's reagent (sulphosalicylic acid). However, Wood[5] elucidated a qualitative test using a 20 per cent aqueous solution. Since then various methods of using sulphosalicylic acid in determined strengths for determining albumin in urine have been described by biochemists, such as Folin[6] and Exton.[7] Hence, its use in clinical chemistry is *not* new.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

McKESSON'S VITAMIN CONCENTRATE OF COD LIVER OIL.—A cod liver oil concentrate having not less than eleven times the minimum vitamin A potency of cod liver oil, U. S. P., and not less than eleven times the vitamin D potency of a potent cod liver oil used as a standard.

Actions and Uses.—McKesson's vitamin concentrate of cod liver oil possesses properties similar to those of cod liver oil so far as these depend on the fat soluble vitamin content of the latter.

Dosage.—From 3 to 6 drops three times daily. A glass dropper is included with the market package, designed to deliver one minim per drop.

Manufactured by McKesson & Robbins, Inc., Bridgeport, Conn. U. S. patent No. 1,690,091 (Oct. 30, 1928; expires 1945). No U. S. trademark.

The vitamin A potency of McKesson's vitamin concentrate of cod liver oil is determined by the method of the U. S. Pharmacopeia: when assayed by this method the product is required to have 5,500 vitamin A units per gram. The vitamin D potency is determined by comparison with a potent cod liver oil containing in each 0.75 Gm. 1 rat unit of vitamin D, the rat unit being defined as that amount of vitamin D which, when uniformly distributed into a standard vitamin D deficient diet—ration 2965, *J. Biol. Chem.* **64**: 263, 1925—will produce in the metaphyses of the distal ends of the radii and ulnae of standard rachitic rats a narrow and continuous line of calcium deposits: when assayed by this method the product is required to have 116 vitamin D units per gram.

RECENT STUDIES IN PERNICIOUS ANEMIA

The greatly accentuated interest that has been displayed in medical circles within the last few years toward the problems of the anemias, and particularly toward pernicious anemia, has brought the blood cells into renewed prominence. Attention has been focused notably on the reticulocytes, the primitive types of blood cells that are an index of the response of the hematopoietic tissue of the bone marrow. It has been asserted that the fundamental defect in hematopoiesis during a relapse in pernicious anemia is due to the inability of the primitive red blood cells of bone marrow to differentiate normally into the adult state. When the regenerative activity of the bone marrow becomes restricted, the numbers of red blood cells in the peripheral blood decrease, and many of those present are abnormal. The liver, kidneys and stomach contain a substance that appears to stimulate the maturation of the primitive red blood cells and consequently to have a therapeutic action in pernicious anemia. A noticeable response signifies the onset of a satisfactory remission.

Recent investigations in two laboratories particularly devoted to the problems of pernicious anemia—namely, the Thomas Henry Simpson Memorial Institute for Medical Research, University of Michigan, Ann Arbor, and the Thorndike Memorial Laboratory of the Boston City Hospital—throw new light on the probable life of the reticulocytes of the blood. Heath and Daland[1] of Boston have followed the changes in these young (rather than degenerative) forms of the adult red blood cell in vitro at 37 C. and in the pleural cavity of animals under conditions resembling to some extent those that are found in the natural circulating medium. The reticulocytes exist thus for from one to five days. They remain for a much longer time when kept in the icebox or at room temperature. The changes that they undergo presumably represent maturation rather than destruction. That the reticulocytes lose their reticular substance and become adult erythrocytes is shown by the fact that the total number of red cells in the incubated specimens of blood does not diminish as the reticulocytes disappear. Evidence is presented by Heath and Daland to show that this must be the case in the blood stream, at least of patients with pernicious anemia at the time of the reticulocyte response following liver therapy.

The Boston investigators remark that whether the maturation of reticulocytes in the blood stream is the same as the maturation that takes place normally in great part in the bone marrow is difficult to determine. A few reticulocytes are found in the circulation in health, and at birth considerable numbers are often present. Heath and Daland have also approached the question of the disposal of the basophilic substance that has disappeared from the young cell in the course of its maturation. It is probable, they believe, that the basophilic substance diminishes gradually in amount as the cell reaches maturity. The observation of the increase of granules in erythrocytes with the decrease of reticulocytes suggests that this is a normal occurrence in the maturation of reticulocytes. The consumption of oxygen by the reticulocytes leads to the possibility of the disposal of the basophilic substance by normal catabolic processes. In studies at Ann Arbor[2] it was estimated that from two to four days is required for the differentiation of reticulocytes in the blood into mature erythrocytes. According to Riddle[2] the rate at which reticulocytes are liberated from the bone marrow into the blood appears to be a factor of importance which influences the rate and magnitude and velocity of the reticulocyte response. The rate of the liberation of the reticulocytes into the blood seems to be proportional to the rate at which they are formed from the more primitive red blood cells within the bone marrow and to the numbers of reticulocytes being formed there. The various students of pernicious anemia agree that, aside from the presence of inhibiting complications in patients with pernicious anemia, the two principal factors that regulate the reticulocyte response to liver therapy are the condition of the hematopoietic tissue of the bone marrow before treatment and the amount of the active principle contained in liver used in treatment.

Indication of some of the metabolic changes incident to blood regeneration has been supplied by Riddle and Sturgis.[3] Endogenous uric acid is manufactured and excreted in large quantities during the period of the reticulocyte response. The amount excreted in excess of the normal excretion is proportional to the increase in the numbers of red blood cells in the blood. It appears that, on the average, with the increase of a million red blood cells per cubic millimeter of blood approximately 10 Gm. of endogenous uric acid is excreted in the urine. The destruction of normoblast nuclei appears to be the source of this endogenous uric acid, and it seems likely, we are told, that the uric acid of endogenous origin normally excreted in the urine is derived principally from this source. Perhaps the endogenous uric acid output will become a reasonably reliable biochemical index of blood production during early remission. The rise in concentration of uric acid of endogenous origin in the blood and its excretion in increased amounts in the urine apparently have the same significance as the increase in the numbers of reticulocytes in the blood, and, according to Riddle, can be detected earlier, as changes in the endogenous uric acid metabolism usually precede similar changes in the reticulocyte concentration in the blood by one or two days.

It is generally conceded that iron therapy is illogical in pernicious anemia. Iron is stored in the body despite the anemia. According to Riecker [4] there is present in blood serum a partly diffusible iron compound the estimation of which may be used to determine the presence and degree of iron starvation in disease and likewise the effect of iron medication. The amount of serum iron is increased in hemolytic diseases of the blood and decreased in the presence of long continued hemorrhage or a dietary deficiency of iron. In pernicious anemia, the level of the serum iron usually is higher than normal but becomes normal during remissions in the disease.

COFFEY-HUMBER TREATMENT FOR CANCER

Following the subsidence of the first flare of publicity, during which sufficient evidence was developed to indicate that the Coffey-Humber method of treating cancer is in no sense of the word "a cure" and that even its efficiency in treatment is exceedingly doubtful, the medical profession settled down to await the careful trial over a long period of time that the discoverers of the method now seem to be anxious to make. This, of course, is necessary for the final decision. Late in August Drs. Coffey and Humber [5] read before the Pacific Association of Railway Surgeons an extensive paper regarding their method. They announce that they have had under their control from January 6 to August some 2,600 patients, and that more than double that number were turned away because not supplied with suitable credentials from their physicians. They state again that they have never made any claim for cure of cancer but are conducting research studies on malignant growths of all types with their special extract of the suprarenal. They have secured a patent to control the manufacture of their product and to prevent its exploitation by any commercial group. Therefore, they now provide a description of the technic by which the extract is prepared. Clinics have been established in San Francisco, Los Angeles and Long Beach. In the period of six months during which the treatment has been used, 13.5 per cent of the patients have died, about as many as would have died without the treatment. The authors are convinced that the product has a vasodilator action. They feel that the pain in cancer is due to vascular constriction and that because of the opposite effect of the extract it has the ability to subdue pain. They are convinced that this effect is not psychologic. According to their tabulated data based on questionnaires sent to 672 patients, 71.5 per cent had pain relieved, 10.3 per cent had never had any pain, 12.8 per cent were not relieved, and 5 per cent were doubtful. This seems to be the most that can be said for the treatment, and the evidence might certainly be better controlled. To continue their research, they have developed a foundation for its promotion. The discussion of the paper did not bring out any points particularly new regarding the method.

In the meantime the resolution adopted by the California Medical Association, apparently endorsing the scientific research and the promotional methods of the investigators, has disturbed a number of the members of that association. They prepared a protest for publication in *California and Western Medicine*, which that periodical has refused to publish. Hence these leading members of the organization are circulating their complaint in mimeographed form, protesting the passage of the resolution, deprecating the nature of the introduction of the method and the sensational publicity, doubting the value of the Coffey-Humber method, and condemning the action of the society in refusing to publish their disclaimer. The controversy is another proof of the danger of attempting to control scientific judgments by political or *viva voce* methods.

Another evidence of the liveliness of this issue on the Pacific Coast is the fact that the Portland, Ore., City and County Medical Society has been compelled to make a decision in response to an offer by the chamber of commerce of Portland to establish a clinic for the investigation of the Coffey-Humber method in that city. The president of the society was authorized to inform the chamber of commerce that it was the opinion of the society that experimentation in Oregon with this method, as with all other methods, should be under the immediate supervision of the University of Oregon Medical School and that a clinic established under such auspices would be given every assistance by the City and County Medical Society. The letter from Dr. Frederick A. Kiehle to the chamber of commerce concludes: "If, however, the recommendation of the council of the City and County Medical Society is not adopted and if an independent clinic is established for the exclusive administration of the Coffey-Humber serum, this council, while unable to give it direct support or encouragement, will nevertheless bespeak for it from the medical profession an attitude of open-minded and friendly interest."

[5] Coffey, W. B., and Humber, J. D.: Extract of Adrenal Cortex Substance, California & West. Med. **33**: 640 (Sept.) 1930.

The history of investigations of new methods for the treatment of cancer is marked, as every physician knows, by the wreckage of dozens of scientific reputations, by the bodies of patients who choose to live or probably to die under experimental methods rather than to take their chance for prolongation of life under the old ones, and by bitter although sincere controversy among scientific men. Such conditions establish again the importance of provision within organized medicine for careful study and judgment of new methods before they are given circulation to the medical profession or to the public. Had the proponents of the Coffey-Humber method seen fit from the first to follow established custom in the introduction of their technic and their results, had they consulted the Council on Pharmacy and Chemistry as to the proper method of introducing a new proprietary, they might have avoided all the acrimony, the criticism, and certainly all the notoriety that has been their lot.

THREE HUNDRED YEARS OF THE CINCHONAS IN MEDICINE

Few drugs that are employed by the physician of today have a history of therapeutic usefulness that reaches back through the centuries. This medical dignity can be claimed proudly by quinine and its companion alkaloids of the cinchona group. The barks of various species of *Cinchona* and *Remijia* (*Cuprea*) contain a considerable number of related substances, among which twenty or more have been isolated and described. They seem to resemble one another in their chemical and pharmacologic properties. The best known representatives are the alkaloids quinine, quinidine, cinchonine and cinchonidine. To thousands of persons quinine has become a household word rather than a scientific curiosity. Generations of physicians have depended on quinine or products that contain it for help in the management of disease.

The cinchonas are natives of western South America but are now cultivated in India and Java. The exact date of the introduction of the use of cinchona bark into medicine is somewhat uncertain. According to Cushny it seems questionable whether the virtues of the bark were known by the native Indians before the invasion of the Spanish. Its introduction into medicine dates from about 1630; hence an international celebration will be held at the Missouri Botanical Garden in St. Louis, October 31 and November 1, to commemorate the three hundredth anniversary of the discovery. Historical records in the possession of the Garden (Shaw's Garden) show that in 1630 Juan Lopez Canizares, Spanish corregidor of Loxa, was the first to demonstrate the use of the bark of the cinchona tree in treating malaria.

Quinine itself was isolated more than a century ago by Caventon and Pelletier[1] shortly before the first U. S. Pharmacopeia was published and at the time when the first steamship crossed the Atlantic. It has an old reputation as an antipyretic. Quinine is commonly described in textbooks as a protoplasmic poison; and it is alleged to produce its effects in the body because of this property, the action being strongest on undifferentiated protoplasm. The comparative safety in the use of the drug is indicated by the fact that it has never achieved any prominence in toxicology. Fatalities from quinine have been exceedingly few. Of course the excelling virtue of the alkaloid in modern medicine remains in its selective toxicity to undifferentiated protoplasm, notably to the plasmodia of malaria. There is some debate as to whether the action is direct or indirect. Quinine is part of the "standard" treatment for malaria. Osler said many years ago that the physician who at this day cannot treat malarial fever successfully with quinine should abandon the practice of medicine.

Current Comment

HORMONE AND CANCER

The effort to influence the growth of cancer by various organ extracts is being widely made at present.[1] Logically it might be profitable to inquire why such trials are being made since every pathologist sees cancer growing freely in those organs whose hormonic activity is high. Moreover, investigators have shown that tumors may be inoculated with ease in the testicle, spleen and brain of mice and rats and may be found as metastatic extensions in the more minute glands of the body. If cancer grows freely in the spleen or the suprarenal or the ovary, why hope to inhibit such growth by an extract made often by crude chemical processes which may alter more sensitive products? The frequency of microscopic metastases in the spleen of human beings seems to have escaped general recognition, perhaps because the most convincing monograph on the subject is in the Dutch language.[2] But one observation is worth many opinions and the fact that extracts, scarcely to be dignified in all cases by the term hormone, do not cause one type of transplanted rat tumor to regress, casts grave doubts on their cancericidal capacity. As this tumor, number 10, regresses spontaneously with considerable facility in many strains of albino rats, any lethal action should be apparent. Among the extracts tried were that from the ovarian follicle, the corpus luteum, three sorts from the spleen and eight suprarenal extracts, including that used on human beings by Drs. Coffey and Humber. Not one of all these products appreciably affected the incidence of regression or the rate of growth of the tumor. The statistical complications introduced by the occurrence of spontaneous recessions have been carefully eliminated. The work of Dr. Bischoff and his colleagues should be repeated with a tumor that does not spontaneously recede and, if the results are the same, should close the discussion on the possible therapeutic action of extracts from the group of organs tested.

THE PROTEIN REQUIREMENT OF THE PRESCHOOL CHILD

The fear of protein in nutrition is subsiding. It is becoming more evident, on the basis of actual experiment, that the body has large powers of adjustment—that it can manage successfully to tolerate diets rich or poor in the organic nutrients. One might expect this of a body that becomes acclimated to a high or a low tension of oxygen in the atmosphere. However, extremes of diet do not interest us in ordinary life as intensely as they do in war, famine and devastating illness. Nitrogen balance can be maintained in adults on a protein intake of about 40 Gm. a day, whereas Stefansson and the Eskimos can live almost exclusively on meat and fish. Of greater concern are the needs of the growing child, whose demands are far better defined than those of the average grown-up and whose opportunities for adequate nourishment largely depend on the selection made by his human guardians. The diet of childhood ought to be emancipated from the fads of the elders. Growth makes sober demands. Much attention has been devoted to the needs of infancy; but the preschool child is just beginning to become the object of serious concern by students of nutrition. In a recent report, Parsons[1] has concluded from his researches that a healthy child of the age group from 4 to 8 years can maintain a positive nitrogen balance on 0.5 Gm. of protein per pound, or 1.1 Gm. per kilogram. These are figures that set the limits for safety in child nutrition.

THE HEKTOEN PHENOMENON IN UNDULANT FEVER

Certain limitations in the diagnostic value of the Widal reaction are at times overlooked. It is of course generally recognized that agglutination of *Bacillus typhosus* is sometimes observed with the serums of healthy individuals who have previously received typhoid vaccine, and occasionally noted in normal individuals with no previous history of this vaccine or of typhoid. Many clinicians have assumed that in these widal-positive individuals decided fluctuations in Widal titer can be produced only by infection with *B. typhosus.* That quantitative fluctuations in specific agglutinins may be produced by other than homologous infections was demonstrated experimentally in 1917 by Hektoen.[2] Within the last few years the Hektoen phenomenon has been confirmed by numerous clinicians, the most recent confirmation being by Gilbert and Coleman[3] of the state department of health, Albany, N. Y. In their study of 150 cases of undulant fever, the Albany investigators recorded suggestive Widal reactions in 23 cases and definitely positive typhoid agglutination in 24 additional cases. Definite fluctuations in typhoid agglutination titer were observed during the course of this nontyphoid febrile infection. Fecal examinations were negative for micro-organisms of the enteric group. About a third of these Widal-positive patients had never had typhoid or typhoid vaccine. From these data Gilbert and Coleman conclude that positive typhoid agglutination reactions "may be encountered in specimens collected from patients during febrile diseases other than typhoid fever, even though the patients have never received typhoid vaccine nor to their knowledge had typhoid fever, and that a fluctuation of the agglutination titer, considered by some as definite evidence of typhoid fever, may occur in cases in which this infection is quite definitely excluded."

TULAREMIA CONTRACTED FROM COYOTES

In June, 1925, Garberson of Miles City, Mont., encountered a case of serologically confirmed tularemia in a man who had been bitten by a coyote puppy (*Canis lestes*). A typical indolent ulcer developed at the site of the coyote bite, accompanied by the axillary adenopathy characteristic of this disease. Careful investigation did not reveal any other probable source of infection. Parker[1] decided to investigate the susceptibility of the coyote to tularemia. Three young coyotes were fed with the tissues of guinea-pigs and Belgian rabbits just dead of tularemia. The coyotes died on the thirteenth, twenty-second and fifty-third day, respectively, after the infectious material was first fed. Emulsions of tissue of the dead coyotes were injected into guinea-pigs. The guinea-pigs died and necropsy revealed the typical spotted spleens and livers and enlarged caseous lymph nodes; *Bacterium tularense* was recovered in pure culture from the guinea-pig tissues. Injections of tissue suspensions of salivary gland tissue from two of the coyotes into guinea-pigs caused their death from tularemia; this discovery introduced the possibility of a new avenue for the transfer of the infection to man by the bite of a wild rodent or carnivore. More recently, Kunkel[2] has reported a case of typical ulceroglandular tularemia in a man who had killed and skinned an adult coyote. Just prior to the disposition of the carcass the patient cut his left index finger with an ax. The primary lesion developed at the site of the cut. There were no other animal contacts before the development of the illness. A blood specimen collected nineteen days after the onset of illness was submitted to the Hygienic Laboratory of the United States Public Health Service at Washington, where the serum was found to agglutinate *Bacterium tularense* in all dilutions to 1 : 1,280, thus confirming the clinical diagnosis of tularemia. While the wild rabbit constitutes the important reservoir of infection for other animals and man, recent reports of new animal hosts and transmitters (woodchuck, opossum, muskrat, European water rat, sheep and quail) and new insect vectors (wood tick of California, *Dermacentor occidentalis* Newmann) indicate the ever-widening spread of the infection to other forms of animal and insect life. This situation is almost certain to result in the perpetuation of the disease among lower animal forms and thus increase the possibilities for the development of the infection in human beings.

Association News

THE PHILADELPHIA SESSION

Dates for Annual Session

The Eighty-Second Annual Session of the American Medical Association will be held in Philadelphia, June 8 to 12, 1931. It was first thought that the session could be held in May but, because of conditions affecting the buildings to be used for exhibits and section meeting places, it was necessary to select June 8 to 12.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10:15 on Tuesday, and 10 a. m. on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

November 3.	Protecting the Surface.
November 4.	Health on Display.
November 8.	Constipation and Colitis.

Five Minute Health Talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

November 3.	A Hard Taskmaster.
November 4.	Too Much Pity.
November 5.	The Art of Accepting Affliction.
November 6.	Hope for the Handicapped.
November 7.	Shattering the Shingles Superstition.
November 8.	Tempests That Trail the Troublesome Tonsil.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Gridiron Banquet.—Three hundred members of Jefferson County Medical Society held a gridiron banquet, October 6, which featured comic solutions of medical problems, a mirth provoking meeting of a board of censors, imitating Birmingham physicians, and a consultation of seven surgeons on a Sunday morning tour of hospitals. Dr. James R. Garber, Birmingham, presided and outlined the use of medical terms as insurance against any serious business entering the meeting.

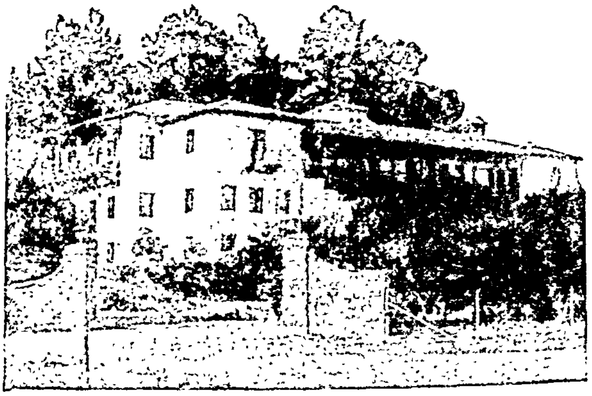
ARKANSAS

Society News.—Dr. Richard S. Weiss, St. Louis, addressed the Tenth Councilor District Medical Society at Fort Smith, September 16, on "Drug Eruptions."——The Mississippi County Medical Society was addressed, September 9, by Drs. Lucius Carl Sanders and Thomas D. Moore, both of Memphis, on cancer of the colon and nephritis, respectively.

CALIFORNIA

Society News.—The Pasteur Society of Central California was addressed, September 24, by Dr. Alfred C. Reed, San Francisco, on animal parasites of man, and Karl F. Meyer, Ph.D., San Francisco, on trichinosis.——The Contra Costa Medical Society was addressed, September 11, at Richmond by Dr. John W. Bumgarner, Richmond, on industrial problems in medical practice, and Dr. Leopold H. Fraser, Richmond, "Fractures Involving Joints."——"Early Respiratory Complications Following Operation" was the subject of Dr. Harold Brunn, San Francisco, before the Fresno County Medical Society, September 9.——Among others, Drs. Thomas C. O'Connor and Robert A. Peers, Colfax, addressed the San Joaquin County Medical Society, September 4, on "Importance of History Taking" and "What to Tell the Tuberculous Patient," respectively.——The Santa Barbara County Medical Society was addressed, September 8, by Dr. Rutherford B. H. Gradwohl, St. Louis, on "Schilling Blood Methods," and Howard S. Duff, D.D.S., Santa Barbara, "Pyorrhea in Its Relation to Systemic Diseases."

Another Metabolic Clinic.—The new Grace Deere Velie Metabolic Clinic at Carmel was opened to the public, August 10, for the investigation of metabolism and the study and treatment of patients suffering from metabolic diseases. While it will not be conducted for profit, any income from the care of patients is expected to defray part of the operating expenses. The clinic was made possible by a bequest of $750,000, of which $250,000 has been expended on the building and equipment. The capacity is twenty-five beds in private rooms. There is a routine clinical laboratory and research laboratories. The initial staff consists of Dr. Rudolph A. Kocher, Paul B. Hartley, Elmer Messner, Ph.D., and Drs. Frederick H. Rodenbaugh and Irving S. Ingber, roentgenologists.



DISTRICT OF COLUMBIA

High Tuberculosis Death Rate.—The city of Washington still has a death rate of 92 persons per hundred thousand of population from tuberculosis. The general average death rate from the disease throughout the country is 70 persons per hundred thousand of population. It is reported that Washington's relatively high death rate is due in part to the higher tuberculosis death rate of its colored population. In 1923 there were 226 deaths per hundred thousand among the colored as compared with 51 per hundred thousand for the white population.

ILLINOIS

Cleveland Program at Quincy.—The fifth annual all-day clinical meeting of the Adams County Medical Society will be held at Quincy, November 17. Dr. George W. Crile, Cleveland, will speak on "Clinical Analysis of 21,135 Operations on the Thyroid Gland with Special Relation to End-Results"; "The Nature and Treatment of Peptic Ulcer," and "Management of Patients Seriously Sick"; Dr. Russell L. Haden, Cleveland Heights, Ohio, "Types and Treatment of Rheumatism"; "Differentiation and Treatment of the Anemias" and "Dental Infection and Systemic Diseases," and Dr. William V. Mullin, Cleveland, "Management of Chronic Diseases of Nasal Sinuses in Relation to Their Effects on Systemic Disease," "Bronchial Asthma" and "The Salivary Glands." Physicians are urged to attend; there is no registration fee.

INDIANA

Society News.—Dr. Robert M. Moore, Indianapolis, addressed the Elkhart County Medical Society, October 2, on "Coronary Occlusion—Some Clinical Observations."——The Third District Medical Society was addressed at New Albany, October 8, by Drs. Emmet F. Horine, Louisville, Ky., on "The Mechanism of the Heart"; Joseph R. Dillinger, French Lick, on "Tonsillitis and Some of Its Sequelae," and Parvin M. Davis, New Albany, on "Intra-Abdominal Abscesses."——The Seventh District Medical Society, Martinsville, was addressed at Indianapolis, October 28, by Drs. Harry E. Mock, Chicago, on "Skull Fractures" and "Joint Fractures," and

Martin H. Fischer, Cincinnati, "Principles of Feeding in Gastric Disease" and "Edema and Albuminuria"; Dr. E. Starr Judd, Rochester, Minn., addressed the evening session on "Clinical Manifestations and Treatment of Peptic Ulcer."——The Indianapolis Medical Society was addressed, October 21, by Drs. Murray N. Hadley and Lyman Pearson, both of Indianapolis, on "Cause of Death in Operative Treatment of Gallbladder Disease" and "Cirrhosis of the Liver," respectively.

Scientific and Medical Displays at State Meeting.—Among the scientific and medical displays at the recent annual meeting of the Indiana State Medical Association at Fort Wayne was a study of the state-wide distribution of physicians prepared by the Indiana University Medical Center. Maps of the state were made showing graphically the variations in ratio of total population to the total number of physicians, the average age of physicians, where the young doctors have settled in the last ten years, and where medical students are coming from. Other maps concerned hospitals, gain or loss in population, road conditions and telephone facilities. The survey was conducted to ascertain the medical needs of the state and to aid young physicians in choosing locations. The work was done under the direction of Dr. Thurman B. Rice. Other displays showed experimental methods and types of apparatus used in pharmacology, necropsy specimens illustrating common disease conditions; motion pictures showing types of orthopedic conditions seen at Riley Hospital; lantern slides and surgical specimens regarding research problems conducted under the Eli Lilly Research Fellowship, and motion pictures of cases of meningitis.

KENTUCKY

Reporters to Cooperate with Medical Journals.—At the recent session of the Kentucky State Medical Association at Bowling Green, the council decided to request the county secretaries to act as reporters for news items for the *Kentucky State Medical Journal* and also of THE JOURNAL.

Society News.—The Christian County Medical Society was addressed, *September 23, by Drs. Nathaniel S. Shofner and* Jack Witherspoon, both of Nashville, on "Diseases of the Thyroid" and "Duodenal Ulcers," respectively.——The Daviess County Medical Society was addressed, September 23, among others, by Drs. William L. Tyler and Joseph R. McGary, Owensboro, on "The Cardiorenal Vascular Syndrome" and "Essential Hypertension," respectively.——Dr. Arthur G. Quinn, Memphis, Tenn., among others, addressed the Four County Medical Society at Fulton, September 30, on "Diseases of the Thymus Gland in Infants."

MARYLAND

Personal.—Dr. William H. Welch, professor of the history of medicine, Johns Hopkins University School of Medicine, Baltimore, received the honorary degree of doctor of laws at the sixty-sixth convention of the University of the State of New York, October 16.

Society News.—The Baltimore City Medical Society was addressed, October 17, by Drs. Gordon M. Holmes, London, England, visiting neurologist at Johns Hopkins Medical School; *Max Kahn, Baltimore, "Pre- and Postoperative X-Ray Treat*ment of Cancer of the Breast"; John A. Askin, Baltimore, "Case of Congenital Anorectal Stricture," and Leo Brady, Baltimore, "Extraperitoneal Pelvic Conditions in Women."

Dr. Weinberg Gives DeLamar Lectures.—The first of the 1930-1931 DeLamar lectures in hygiene, arranged annually by the Johns Hopkins University School of Hygenie and Public Health, were given, October 21-22, by Dr. M. Weinberg of the Pasteur Institute, Paris, on "Rôle of Anaerobic Bacteria in Human Pathology" and "Serotherapy of Medical and Surgical Infections Caused by Anaerobic Bacteria." These lectures are supported from the fund bequeathed to the medical school by Joseph R. DeLamar, in accordance with his will "to give to the people of the United States generally the benefits of increased knowledge concerning the prevention of sickness and disease and also concerning the conservation of health by proper food and diet."

MASSACHUSETTS

Annual Meeting of New England Surgical Society.—The thirteenth annual meeting of the New England Surgical Society was held at Boston, September 29-30. Among others, papers were delivered by Drs. George A. Leland, Jr., on "Some Aspects of the Treatment of Cancer of the Cervix"; George G. Smith, "Palliative Operations for Advanced Cancer of the Bladder"; Robert B. Greenough and Joseph C. Aub, "The Lead Treatment of Cancer," and Henry Jackson, Jr., "Biological Aspects of Cancer." Several clinics were held at the Boston City, Massachusetts General and Peter Bent Brigham hospitals.

Dinner to Dr. Benedict.—Francis G. Benedict, Ph.D., director, since 1907, of the Nutrition Laboratory of the Carnegie Institution of Washington, Boston, was guest of honor at a complimentary dinner given, October 3, by his associates on the occasion of his sixtieth birthday. George H. Parker, S.D., professor of zoology, Harvard University, presided at the dinner. Among the speakers were Drs. Eugene F. Du Bois, medical director, Russell Sage Institute of Pathology; Elliot P. Joslin, clinical professor of medicine, Harvard Medical School, and George W. Crile, Cleveland; Allan Winter Rowe, Ph.D., director of research at the Evans Memorial, presented Dr. Benedict with a handsome volume containing congratulatory letters from scientists all over the world.

MICHIGAN

Dr. Burr Honored.—The honorary degree of master of *arts was conferred on Colonel B. Burr, Flint, at the eighty*-second opening assembly of the University of Michigan Medical School, Ann Arbor, by Alexander G. Ruthven, president of the university. Dr. Burr, a retired physician and psychiatrist, former superintendent of the Eastern Michigan Asylum, Pontiac, is the author of the recent two volume "Medical History of Michigan." Dr. Burr was formerly a member of the faculty and historian of the university.

Society News.—The Wayne County Medical Society was addressed, October 7, by Dr. Clarence D. Selby, Toledo, Ohio, on "The Diagnosis of Injuries."——The Detroit Pediatric Society was addressed, October 1, by Drs. William S. O'Donnell on "Treatment of Edema in Tuberculous Nephritis."——The Calhoun County Medical Society was addressed, October 7, by Mason Sinai, D.P.H., Ann Arbor, on "Trends in Medical Economics."——The Grand Traverse-Leelanau County Medical Society was addressed, August 12, by Dr. Cyrus C. Sturgis, Ann Arbor, on "Treatment of Pernicious Anemia."——Dr. Alfred L. Arnold, Jr., Owosso, exhibited a film entitled "Treatment of Normal Breech Presentation" before the Shiawassee County Medical Society at its *September meeting.*——The fifth annual clinic of the Highland Park Physicians' Club will be held, December 4, at the Highland Park General Hospital; among the participants will be Drs. Dean D. Lewis, Baltimore; Ernest E. Irons, Chicago; Charles S. White, Washington, D. C., and Alexander Primrose, Toronto, Ontario.——The first of the series of graduate courses in medicine and surgery to be conducted by the Wayne County Medical Society was given by Drs. Elisha S. Gurdjian, September 26, on "Head Injuries" (surgery); Frank S. Perkins, September 30, "Dietotherapy" (medicine); Arthur E. Schiller, October 3, "Tumors and Ulcers of Face" (surgery); Richard M. McKean, October 7, "Hypertension and Nephritis" (medicine); William E. Johnston, October 10, "Thyroid" (surgery); beginning October 14, the course was given by Dr. Don W. McLean on "Diabetes" (medicine); October 17, Claire L. Straith, "Plastic Surgery" (surgery); October 21, Daniel P. Foster, "Obesity and Other Nutritional Problems" (medicine).——Dr. Joseph T. Wearn, Cleveland, addressed the medical section of the Wayne County Medical Society, October 14, on "How the Heart Grows Old."——The medical reserve corps group courses begun, *October 6, will be continued the first and third* Mondays of each month until spring. The schedule includes the subjects of medical department administration, elementary military sanitation, service with medical detachments, medical tactics and medical service of the field force. These will be offered as basic and advancement courses. Further information may be obtained from Major Harrison W. Stuckey, medical executive, 438 Book Tower.

MINNESOTA

Unlicensed Practitioner Sentenced.—J. E. Dufort, Northome, was recently given a suspended sentence of one year in the county jail and required to pay a fine of $100 for practicing medicine without a license. Dufort has been located at Northome for twenty years and has never possessed a license to practice medicine anywhere. He was arrested in 1928 charged with violating the basic science law, and was arrested again in June, 1930 (THE JOURNAL, Jan. 19, 1929, p. 237).

Society News.—The Minnesota Academy of Medicine was addressed, October 8, by Dr. John Charnley McKinley, Minneapolis, *on "Familial Diffuse Sclerosis of the Brain,"* and *by* Drs. Frederic E. B. Foley and Arnold Schwyzer, St. Paul, on "An Improved Pelvio-Ureteroplastic Operation for Hydronephrosis."——Dr. Solon Marx White, Minneapolis, addressed the Interurban Academy of Medicine at Duluth recently on "Arthritis Deformans."——"Serum Reactions" was the subject of Dr. Reuben A. Johnson, Minneapolis, before the Scott-Carver County Medical Society recently.——Dr. George E.

Fahr, Minneapolis, began a series of talks on cardiology before the Park Region District and County Medical Society, October 8, at Alexandria, on "Management of the Ambulant Cardiac Patient."——"Sciatica" was the subject of a paper read by Dr. Andrew P. MacKinnon, Winnipeg, Manit., among others, before the Red River Valley Medical Society at Warren, October 9.——Dr. Arthur I. Arneson, Starbuck, addressed the West Central Minnesota Medical Society at Morris, October 8, on blood chemistry, and Dr. Charles L. Scofield, Benson, on the relation of physicians to the state board of health.

NEBRASKA

Society News.—Dr. John S. Musser, New Orleans, addressed the Omaha-Douglas County Medical Society, October 20, on "Oral Cavity in Certain Systemic Diseases"; the society was addressed, October 28, by Drs. Maurice C. Hennessy, Council Bluffs, on "County Health Situation in Council Bluffs"; Alfred J. Brown, Omaha, "Influence of Cervical Paravertebral Anesthesia on the Pulse Rate During Operations on the Toxic Thyroid Gland," and James T. Maxwell, "Ethyl Chloride as a General Anesthetic."——Dr. John L. Morse, Boston, addressed the student body and faculty at the University of Nebraska Medical College, October 9, on "Chronic Indigestion in Children."

NEW YORK

Trichinosis Made Reportable.—The public health council, September 17, amended the sanitary code making trichinosis one on the list of communicable diseases to take effect October 1. Official attention was called to the fact that undulant fever and tularemia are also reportable.

Personal.—Dr. Lloyd H. Ziegler recently accepted the professorship of neurology and psychiatry at the Albany Medical College, having resigned from the staff of the Mayo Clinic; Dr. Ziegler will also be neuropsychiatrist-in-chief of the Albany Hospital.——Dr. William P. Brown, medical director of the Pennsylvania Tuberculosis Society, has been appointed superintendent of the Pawling Sanatorium, Wynantskill, the tuberculosis hospital for Rensselaer County.

Septic Sore Throat in Kingston.—An outbreak of septic sore throat in Kingston which began the last week in August resulted in 151 known cases and 6 deaths. It was estimated that the epidemic involved 700 cases. Investigations of eighteen dairy farms, begun September 5, revealed that the bulk of the cases were on the route of two dealers who purchased raw milk from one dairy in which two milkers were found to have had sore throat and the owner to have previously had sore throat from which cultures showed the presence of hemolytic streptococci. Up to September 22, 98 families, comprising 340 individuals, were visited on one route, and 117 cases were discovered. On the second route, 99 families, comprising 297 individuals, were visited, and 34 cases were discovered. Examinations of milk from an injured cow in the herd of the implicated dairy revealed the presence of hemolytic streptococci which were from a morphologic and cultural point of view identical with the organisms secured from the patients' throat. The epidemic began to subside immediately after the infected cow was excluded from the herd.

Society News.—The fourth annual conference of secretaries of county medical societies, held at Albany, September 9, with representatives of twenty-one counties present, considered the policy of cooperation between physicians and state health officers on the matters of public health.——The Medical Society of the County of Nassau was addressed, September 30, at Hempstead by Dr. Richard Kovacs, New York, on diathermy.——The Bronx County Medical Society was addressed, October 15, by Drs. Joseph H. Gettinger, New York, and George F. Chandler, Kingston, on "Mass Production and Wholesale Distribution in Medicine" and "Thoughts on Medical Economics."——The twenty-fourth annual meeting of the Seventh District Branch Medical Society of the state of New York was held at Penn Yan, September 24. Among others, talks were made by Drs. John L. Eckel, Buffalo, on "Anterior Poliomyelitis"; William Wayne Babcock, "Resuscitation," and James E. Talley, Philadelphia, "Care of the Heart in Certain Infections."——The Medical Society of the County of Kings was addressed, October 21, by Drs. William H. Ross, Brentwood, president of the Medical Society of the State of New York, on present day trends in medical public relationships; James E. Sadlier, Poughkeepsie, "Need of Medical Leadership in Public Health Relations," and John A. Card, Poughkeepsie, "Malpractice Insurance."——The Brooklyn Society of Internal Medicine was addressed, October 24, by Dr. Richard Kovacs on "Present Day Use of Hydrotherapy, Including American Spa Methods"; Dr. Walter P. Anderton delivered a medical travelogue on "Some French and English Spas."——A symposium on cardiology was conducted by the East New York Medical Society, October 27.——Dr. Fred Maurice McPhedran, Philadelphia, addressed a joint meeting of the Queensboro Tuberculosis and Health Association and the Medical Society of the County of Queens, September 23, at Bayside on "Some Aspects of the Prevention of Tuberculosis in Children."——Dr. Walter L. Niles, New York, addressed the Suffolk County Medical Society, October 30, at Riverhead on "Digitalis Therapy in Pneumonia."——Dr. Walter J. Highman, New York, addressed the Medical Society of the County of Albany, October 24, on "The Nature of Eczema."

New York City

Appointments at Cornell.—Dr. Herbert F. Traut, assistant in obstetrics, Johns Hopkins Medical School, Baltimore, has been appointed associate obstetrician of the New York Hospital and associate professor of obstetrics and gynecology in the Cornell University Medical College. Dr. Robert Gordon Douglas, instructor in obstetrics, Johns Hopkins Medical School, has been appointed assistant obstetrician of the New York Hospital and associate in obstetrics and gynecology in the medical college. These appointees are to assume active duty in the new plant, which is now under construction, under Dr. Henricus J. Stander who has been appointed obstetrician-in-chief of the New York Hospital and professor of obstetrics and gynecology in the medical college. Dr. Stander was formerly associate professor of obstetrics at Johns Hopkins.

Society Endorses Compensation Agreement. — The Comitia Minora of the Medical Society of the County of New York, October 13, endorsed an agreement with the compensation insurance carriers of the state. The society aims to get the carriers to recognize treatment of compensation claimants by qualified physicians without formal authorization from employers. The carriers aim to give the employee proper administration of the workmen's compensation law involving skilful medical and surgical care; prompt and proper completion of forms for prompt compensation pay, and that physicians' bills be reasonable and promptly forwarded to companies and not to the compensation commission and promptly paid. The carriers agreed to correct the erroneous opinion that they indiscriminately lift cases of injured employees from the care of competent family physicians of those employees. They agreed that reasonable charges for services of family physicians will be promptly paid. In the furtherance of these aims, the county society agreed to instruct members of the importance of proper treatment to bring the injured employee back to efficiency as soon as possible. The carrier is to be consulted when there is doubt of proper handling of any case. The society will arrange fee schedules with the carriers to which physicians must conform. All disputes will be decided on by an arbitration board representative of the physicians and carriers. The society members agreed to seek advice and abide by the decision of the carriers concerning consultations, roentgen examinations and other treatments beyond the ordinary, and will give at reasonable times carrier examinations of claimants except where the physician must act quickly in dire emergency. The society will schedule meetings to be addressed by specialists in industrial medicine and surgery and by qualified interpreters of the workmen's compensation law. The carriers agreed to furnish literature and other aid in instructing members of county medical societies concerning industrial medical and surgical fields and in regard to the detail of paper work necessary in the efficient administration of the compensation law.

OHIO

Hospital News.—The total expense of operating nineteen hospitals in Cleveland participating in the Community Fund for 1929 was $5,500,432, it is reported, of which $951,212 was paid from the Community Fund. The total of 69,820 patients were given 793,846 days of care.

Personal.—Dr. Carl H. Lenhart was recently added to the faculty of the School of Medicine of Western Reserve University, Cleveland, as professor of clinical surgery and as chief of the division of surgery of the City Hospital. Dr. Lenhart will retain his office as director of the surgical division of St. Luke's Hospital but will give half his time to the new position at City Hospital.

Conference on Adolescence. — The first conference on research on adolescence sponsored by Western Reserve University and the Brush Foundation was held, October 17-18, at Cleveland. A specially selected group was chosen to attend. The conference dealt with changes which take place in the child during the second decade including the relations between the development of the body and mind during adolescence, the effects of nutrition, and the endocrine glands on development, studies on adolescent behavior and the organization and development of personality. Among the speakers were Dr. Wingate Todd, on "Adolescence as a Practical Study"; Dr. Norman W. Ingalls, "Sex Features in Adolescence"; Elmer V. McCollum, Sc.D., Baltimore, "Nutritional Considerations in the Second Decade"; George E. Coghill, Ph.D., Philadelphia, "Anatomical Growth of the Nervous System in Relation to Behavior," and Frederic L. Wells, Ph.D., Boston, "The Ethics, Objectives and Practical Value of Psychometry."

TENNESSEE

Hospital News.—Nineteen Memphis physicians who specialized in diseases of the eye, ear, nose and throat recently organized a holding company known as the Meenath Corporation for the purpose of insuring the operation of the Memphis Eye, Ear, Nose and Throat Hospital. The name of the corporation is made up by combining the initials from the various words making up the name of the hospital. The incorporators have agreed to support the hospital with part of their work in order to carry on the good work of the institution. Free clinics will be continued for sufferers from the diseases of the eye, ear, nose and throat as in the past, and a special hay-fever clinic will be conducted on certain days. Any indigent patient of Memphis or vicinity may receive service at these clinics extended by the staff.

Appointments at Vanderbilt.—The following additions to the staff of Vanderbilt University School of Medicine, Nashville, were recently announced, it is reported:

Dr. Samuel M. Bloomstein, associate professor of clinical pediatrics.
Dr. Robert Boyd Bogle, associate professor of clinical dental surgery.
Walter N. Morgan, D.D.S., associate professor of clinical dental surgery.
Oren A. Oliver, D.D.S., associate professor of clinical dental surgery.
Dr. Richard Ashman, Ph.D., assistant professor of physiology.
Dr. Sam L. Clark, assistant professor of anatomy.
Dr. Harry T. Hillstrom, assistant professor of surgery in charge of radiology.

All classes of the school of medicine have their full quota enrolment, classes being limited to 50 for each class. There were 645 applications for admission to the school for the fall term, it is reported, with 601 of these for the freshman class, and 41 for advanced standing from other accredited medical schools, the total representing a 33 per cent increase over the number of applicants for admission last school year.

TEXAS

Personal.—Dr. John W. Burns, Cuero, was recently appointed a member of the state board of health to fill the vacancy created by the resignation of Dr. Joseph Gilbert, Austin; Dr. Gilbert resigned to become physician at the University of Texas, a position which he formerly held, it is reported.——Dr. George H. Spivey resigned, September 1, as director of the Winkler County Health Unit, Wink, to accept a similar position, it is reported, at Phoenix, Ariz.

University Faculty Changes.—The following changes, among others, in the faculty of the University of Texas School of Medicine, Galveston, have recently been announced:

Dr. Felix L. Butte, who has been on leave of absence in the Cleveland City Hospital for the last year, will return as associate professor of anatomy.
Dr. John V. Sessums, associate professor of anatomy.
Marion Fay, Ph.D., associate professor of biologic chemistry.
Dr. Harry L. Klotz, adjunct professor in department of pathology.
Dr. Charles H. Taft, New Haven, Conn., associate professor in department of pharmacology.
Dr. Robert Milo Moore, St. Louis, associate professor of experimental surgery.

In the department of biologic chemistry, Meyer Bodansky, Ph.D., will become the head of the laboratories of John Sealy Hospital but will retain a teaching connection with the school of medicine as professor of the newly created department of pathologic chemistry. Elective courses for juniors and seniors will be offered as soon as the course is organized.

Society News.—The Dallas County Medical Society conducted a symposium on goiter, September 11, the speakers being Drs. Paul H. Duff, Robert M. Barton and Walter E. Sistrunk, Jr., all of Dallas.——"Spinal Anesthesia" was the subject of Dr. Herschel F. Connally, Waco, before the Falls County Medical Society, September 8; Dr. Joel I. Collier, Marlin, presented a case of sinus infection.——The Harris County Medical Society was addressed, September 10, by Drs. George M. Brandau, Houston, on "Incidence of the Sickle Cell Trait in Industrial Workers," and Archie L. Mitchell and Byron P. York, Houston, "A Simple Method of Transfusing Infants and Children."——"Whole Blood Transfusion" was the subject of Dr. Julius T. Krueger, Lubbock, before the Lubbock-Crosby Counties Medical Society, September 9.——Dr. Conrad Frey, Melvin, spoke on "Myelogenous Leukemia" before the McCulloch County Medical Society; a second feature of the program was a round table discussion of medical problems, both scientific and economic.——The Potter County Medical Society was addressed, September 8, by Dr. Elisha A. Metzger, Amarillo, on "Injection Treatment of Varicose Veins of the Leg."——The Tom Green County Medical Society was addressed, September 1, at San Angelo, by Drs. Charles L. Martin, Dallas, on "Cancer of the Mouth and Neck"; Hugh Leslie Moore, Dallas, "Secondary Diarrhea in Infants," and D. D. Wall, San Angelo, "Rectal Anesthesia in Obstetrics."——Among others, Drs. Orman T. Kimbrough, Wichita Falls, and Ernest H. Bursey, Fort Worth, addressed the Thirteenth District Medical Society, September 9, at Wichita Falls, on "Conditions of Upper Urinary Tract Due to Adnexal Disease" and "Thrombopenic Purpura Hemorrhagica," respectively.

VIRGINIA

Society News.—The Southwestern Virginia Medical Society was addressed, September 23-24, among others, by Drs. James C. Motley, Abingdon, on "Relation Between General Medicine and Mental Hygiene," and John E. Gardner, Roanoke, "Acute Bichloride of Mercury Poisoning," with a case report.

Personal.—Dr. Fred J. Wampler, professor of preventive medicine at the Medical College of Virginia, Richmond, has been granted a leave of absence to serve as a member of a commission sponsored by the Institute of Social and Religious Research of New York City to make a study of missions in India.

University News.—Fundamental health services performed by the Medical College of Virginia through its hospitals and clinics increased from a total of 55,866 in 1928-1929 to 67,888 in 1929-1930. In addition to the health services rendered, the colleges last year gave instruction to 879 students in its four schools of medicine, dentistry, pharmacy and nursing.——Free dental work of white pupils of Richmond in public schools will be done during the session 1930-1931 at the Medical College of Virginia, for which it has appropriated $5,000. A graduate operator and supervisor is in charge of this clinic and three undergraduate students will do the work under his instruction.——An engraving of William Harvey was recently presented to the Medical College of Virginia by Dr. Joseph L. Miller, Thomas, W. Va.; it bears the date 1739 and was made by I. and P. Knapton, London. Dr. Miller recently presented to the Richmond Academy of Medicine a library dealing with the history of the medical profession. The library will be placed in the building soon to be erected and will be used jointly by the college and the academy for library purposes.

GENERAL

Increase of Meningitis.—According to the U. S. Public Health Service there has been a progressive increase in the number of cases of meningococcus during the past five years; 1,859 cases were reported for 1925 and 9,660 for 1929. Since March, 1930, the reported prevalence of the disease has been lower than it was in the corresponding months of 1925. In comparison with the prevalence of the disease over the world, an increase in the United States was noted between 1915-1917 but the number of cases did not rise noticeably in Europe until 1929. An outbreak of meningococcus meningitis early this year was noted in the Anglo-Egyptian Sudan, and also the French Protectorate of Morocco with a slight increase of incidence in Mexico.

Another Journal on Pathology.—Beginning January, 1931, the American Society of Clinical Pathologists will publish a bimonthly journal known as the *American Journal of Clinical Pathology*. This journal will publish original papers dealing with all phases of clinical pathology and closely related subjects. The editors will also make an effort to publish articles dealing with new methods and comparisons of old methods in the application of clinical pathology to medicine and surgery. Manuscripts should be sent to Dr. Thomas B. Magath, editor, Mayo Clinic, Rochester, Minn. The advisory editorial board consists of Drs. John A. Kolmer, Philadelphia; Arthur H. Sanford, Rochester, Minn.; Bowman C. Crowell, Chicago; Robert A. Keilty, Washington, D. C.; Frank W. Hartman, Detroit; Herbert Fox, Philadelphia; Kenneth M. Lynch, Charleston, S. C.; Stanley P. Reimann, Philadelphia; Walter S. Thomas, Clifton Springs, N. Y.; Robert A. Kilduffe, Atlantic City; Harry J. Corper, Denver, and C. S. Butler.

National Certification Board on Obstetrics and Gynecology.—The American Board of Obstetrics and Gynecology, composed of nine members and examiners, elected by the American Association of Obstetricians, Gynecologists and

Abdominal Surgeons, the American Gynecological Society, and the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, was formally organized in Niagara Falls, September 16. The board will grant certificates indicating proficiency and specialization in obstetrics or gynecology, or both, to those who comply with its requirements. The board is now prepared to receive applications from experienced and qualified obstetricians and gynecologists. This board has been in process of organization since 1927. It is hoped and expected that its certificate will have considerable weight in the minds of hospital trustees and other laymen as well as in many important medical circles whenever a question arises as to an individual's special ability in obstetrics and gynecology. Detailed information and application blanks may be secured from Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh, Pa.

The National Institute of Health.—Plans for expansion of the new National Institute of Health, established by Congress in May, are under consideration by the U. S. Public Health Service. The institute has three divisions at present —pharmacology, chemistry, and pathology and bacteriology. According to a statement by Dr. Ralph C. Williams, assistant surgeon general, in a recent issue of the *United States Daily*, the addition of two new divisions, physiology and physics, are contemplated. It has been proposed that work in industrial hygiene will be developed probably under the division of chemistry to include the study of problems involved in the study of industrial problems, proper heating, light and ventilation, and industrial poisons in relation to health. It is also planned to erect a three story addition to each of the two present buildings and to construct two new buildings in order to provide more space for research workers and permit expansion of activities into new fields. The institute hopes later to have a farm near Washington where animals used in health research may be raised. It is intended to submit the full plan of extension to Congress, which, at its next session, will be requested to make available the $750,000 construction fund authorized under the law creating the institute.

Society News.—The Polish Medical and Dental Association of America at its annual meeting in Chicago, October 2-4, elected Dr. Kasimier G. Cieslak, Cleveland, president, and P. J. Wawrzynski, D.D.S., Lakewood, Ohio, secretary. Dr. Irving S. Cutter, dean, Northwestern University Medical School, Chicago, gave an address on "Poland's Contribution to American Hygiene and Sanitation."——At the forty-first annual meeting in Denver, October 14-16, of the Association of American Medical Colleges, the following officers were elected: President, Dr. Maurice H. Rees, Denver; vice president, Dr. Charles C. Bass, New Orleans, and secretary-treasurer, Dr. Fred C. Zapffe, 25 East Washington Street, Chicago (reelected). The next annual meeting will be held in New Orleans in 1931.——The Children's Hospital Association of America held its annual meeting at New Orleans, October 23; among the speakers were Drs. Charles C. Hedges, New York, and Laurence R. De Buys, New Orleans, whose subjects were "The Organization and Operation of a Pediatric Outpatient Department" and "Management of a Children's Service in a General Hospital," respectively.——The Central States Pediatric Society will hold its annual meeting, November 7-8, in Memphis; the society is composed of men doing pediatrics in the territory extending from Pittsburgh to Denver, inclusive, and all physicians in this region are cordially invited to attend. Among the speakers will be Drs. Maud Loeber, New Orleans, "Evaluation of Gastric Analyses and Stool Examination in a Series of Cases When No Other Pathology Has Been Found to Account for Anorexia, Loss of Weight and Capricious Appetite"; Edwin G. Schwarz, Fort Worth, Texas, "Is the Allergic Individual More Susceptible to Poliomyelitis?" Madison Hines Roberts, Atlanta, Ga., "A Study of Approximately Five Hundred New-Born Infants, Born of Syphilitic Mothers," and John A. McIntosh, Memphis, "The Relationship of Metazoal and Protozoal Infestation to Vitamin B Deficiency."——The National Society for the Prevention of Blindness has been conducting a series of lectures given to classes for training sight-saving class teachers at the Universities of Cincinnati and Chicago, Columbia University and the State Teachers' College at Buffalo with Dr. Benjamin Franklin Royer, medical director, in charge.

Southern Medical Association Meeting.—At the twenty-fourth annual meeting of the Southern Medical Association, Louisville, Ky., November 11-14, papers will be presented by Drs. Lucius E. Burch, Nashville, Tenn., on "Ephraim McDowell and Ovarian Surgery"; Surg. Gen. Hugh S. Cumming, U. S. Public Health Service, Washington, D. C., "Future Relations of the Profession to the Public"; E. Starr Judd, President-Elect, American Medical Association, Rochester, Minn., "Some of the Historical Points Connected with the Development of Surgery of the Biliary Tract"; Thomas Parran, Jr., state health commissioner of New York, Albany; Walter L. Treadway, Washington, D. C., "Relationship of Neuropsychiatry to the Field of Public Health"; Surg. Gen. Merritte W. Ireland, "Relation of Internal Medicine and Surgery"; Hugh Leslie Moore, Dallas, Texas, "A Clinical Observation in Nutritional Injuries"; George W. F. Rembert, Jr., Jackson, Miss., "Gastro-Enterology: An Important Phase in Diagnostic Procedure"; Ernest W. Goodpasture, Nashville, Tenn., "Cytotropism and Virus Infection of the Nervous System," illustrated; Robert Finley Gayle, Jr., Richmond, Va., "The Relationship between Neurology and General Medicine and Surgery"; John W. Pierson, Baltimore, "Some Bone Changes Associated with Diseases of the Hematopoietic System"; Jeffrey C. Michael, Houston, Texas, "Advisability of a Revision of Dermatologic Nomenclature"; John W. Turner, Atlanta, "Chronic Salpingitis"; the section on obstetrics will conduct a symposium on maternal welfare and the section on urology one on treatment of gonorrhea. During the same week other associations will meet as follows: Conference of City and County Health Officers of Kentucky; the sixteenth annual meeting of the Women Physicians of the Southern Medical Association; the third annual conference of medical work in connection with the Veterans' Pension Claims by the Medical Referee of the Bureau of Pensions and the Pension Examining Surgeons; the Southern States Association of Railway Surgeons; the National Malaria Committee and the Southern Association of Anesthesists and the Mid-Western Association of Anesthetists. Entertainment will include a golf tournament and trap shooting, with receptions and luncheons for visiting ladies.

Report of Children's Fund.—The report of the Children's Fund of Michigan for the first year, ended April 30, 1930, shows that a health demonstration in Menominee County introduced modern methods of sanitation, medical inspection of school children, preventive disease campaigns, and health education movements. Arrangements have been made to establish the Northern Michigan Child Clinic at Marquette, to be operated at St. Luke's Hospital with assistance from the University of Michigan. Two health units, each comprising four counties, were established with headquarters at Grayling and West Branch. The Orthodontia Clinic at the Children's Hospital of Michigan, Detroit, was remodeled, enlarged and granted funds. To give dental service in rural areas, dentists trained in public health service were sent to thirteen counties, where defects in 85 per cent of the children's mouths were found. The trustees decided to supply ten counties with nurses for a limited time to encourage residents to engage nurses from their own funds. Nurses were sent to three counties to give instruction in prenatal care. Two women physicians were engaged to spend a month in a county, giving lectures and demonstrations on phases of mother and child care. Funds were given to the Michigan State Medical Society to conduct graduate clinics for physicians practicing children's specialties. This program resulted in the inspection of 10,280 school children by nurses; 3,593 preventive treatments for diphtheria; 1,492 vaccinations against smallpox; 3,354 physical examinations by physicians, and 7,593 children inspected by dentists. Funds were supplied for research on dental caries at the University of Michigan on orthodontia and on juvenile delinquency at Detroit. The latter is one of three centers in Michigan established by the Institute of Human Relations of Yale University. Funds were given to aid in a survey of child dependence made by the Child Welfare League of America that it might shape its policies to avoid duplication and effort; 552 dependent children in northern Michigan were aided by appropriations by the Michigan Children's Aid Society. The fund made an appropriation to establish a behavior clinic in Grand Rapids allied with the public schools, and provided funds for an experimental playground for preschool children, and helped the parent-teachers associations in the distribution of twenty-six loan collections of books to children removed from libraries, reaching 9,555 children. The Children's Fund is financing for three years a cooperative program with the department of public instruction and education for a health education course to be given at normal colleges. The trustees are at work on a child guidance program and have joined with the Individual Psychology Foundation and the Detroit Society for the Scientific Study of Character to demonstrate the value of psychiatric skill in treating problem children. The fund plans to erect a building for administrative offices and laboratory facilities located near the Children's Hospital of Michigan. The sum of $384,790.86 has been added as earnings to the contribution of Senator Couzens of $10,000,000. Appropriations totaling $740,697.92 have been made, of which $156,715.44 has been disbursed.

there were indications that the number and ratio of the unfit were increasing. If the process was allowed to continue, national degeneracy was merely a matter of time. The only way to avoid it was by increasing the propagation of the fit and preventing that of the unfit. Partial intervention by man in the shaping of his destiny could end only in disaster. Not only was eugenics necessary, but the logical consequence of the steps he already had taken. Before the state would take some definite action, the public conscience must be awakened and the essential thing was the education of public opinion as to the responsibilities of parenthood. In this the church, with its opportunities of teaching, could render incalculable service to mankind.

An "Honors Medical School"

St. Mary's Hospital is one of the smaller London hospitals with a medical school. It contains 350 beds, but upward of 700 beds are available for clinical teaching in affiliated institutions, so that there is no lack of material for this purpose. But the school is ambitious and progressive and has achieved something not attempted by the larger schools. Its motto is "quality, not quantity" and it is what its dean calls an "honors medical school." It confines the number of students admitted each year to fifty, who are not, as in other schools, simply men who have passed a qualifying examination entitling them to be medical students, but picked men. This year forty-eight men competed for entrance scholarships, which are awarded not by examination but by nomination, after careful consideration of the records and reports by headmasters and college tutors. In the first instance the candidates are singled out by those who report on them as the most deserving and promising of their year. The introduction every year of a considerable number of such men means that they constitute a fair proportion of the total students of the school, and this proportion is increasing. It provides the nucleus of an honors school such as exists nowhere else in England. The school is being rebuilt and will soon have buildings and laboratories of the most modern type, which will embody everything that experience of America and the continent has proved desirable. The Institute of Pathology and Research is under the personal direction of Sir Almroth Wright, whose work on vaccine therapy is so widely known.

"The Peking Man"

In The Journal, May 10, p. 1516, it was stated that Prof. Elliot Smith regarded the discovery of a skull at Choukoutien, near Peiping, as probably the most important contribution to knowledge of early Pleistocene man that has been made. It is so important that a special name, *Sinanthropus*, has been given to this new member of the human family. It presents features analogous to *Pithecanthropus* and Neanderthal man but belongs to a genus distinct from both. The base of the skull, unfortunately unknown in the case of *Pithecanthropus*, displays startlingly simian characters. Prof. Elliot Smith is now visiting Peiping at the invitation of the Chinese government for the purpose of studying the *Sinanthropus* remains. In a lecture delivered before the Chinese Geological Society he stated that the remains are "the most valuable and illuminating evidence of man's early history yet revealed." He declared that the judgment he had previously formed on the basis of written reports was an underestimate of the importance of the discovery, the significance of which transcends his most sanguine hopes. He considers that when the report of Dr. Davidson Black, the Canadian anatomist lent to the Geological Survey of China by the Rockefeller Foundation, on the cast of the brain cranium, now in course of preparation, is submitted, "a flood of light will be thrown on the organ responsible for conferring on man his human qualities of mind and skill."

Birth Control Sanctioned by Indian State

A step without precedent in India, or in the British empire, has been taken by the government of the Indian state of Mysore, which has given official approval to the establishment at the four principal hospitals of state birth control clinics. Dr. Subba Rao, the senior surgeon of Mysore and principal of the Medical College of Bangalore, an Indian who received his medical training in Madras and London, recently drew up proposals for the establishment of contraceptive clinics at the four large hospitals of the state. In submitting his scheme to the government he pointed out that many women were so debilitated by ill health or frequent child bearing that maternity was inadvisable both in their interests and in those of their progeny. He therefore suggested that they should be instructed in contraception by women physicians. He proposed that the women medical officers at the Victoria Hospital, the Maternity Hospital at Bangalore and two other hospitals at Mysore should be authorized to give this instruction to those who had bona fide reasons for acquiring it. He proposed that contraceptive appliances should be kept in stock at these hospitals and supplied at cost, and finally that Dr. C. V. Natarajan, who has made a special study of contraception in America, should cooperate with the women physicians by giving advice as to the development of the clinics. He made it clear that the women physicians would give advice only to married women who needed it for considerations of health or for economic reasons. It is announced in the Mysore government gazette that official approval has been given to the proposals, and expenditure has been sanctioned for the purchase of contraceptive appliances to be kept in stock at the hospitals.

Variations in Efficacy of Antidiphtheritic Serum

Addressing recently the Academy of Medicine, Mr. Jules Renault, "inspecteur général" of the ministry of public health, presented a communication on the interpretation of the variations noted by physicians in the efficacy of antidiphtheritic serum, which, it appears, is not the same in different countries and at different times. The variations have usually been ascribed to the different mode of preparation—to the differences in the number of the antitoxic units. The ordinary French serum contains from 300 to 350 units, although the pharmacopeia requires only 250 units. The failures are due, according to Mr. Renault, to various causes. In the first place, there is the peculiar gravity of certain epidemics. There may be also other additional diseases, or association with pernicious microorganisms, such as the streptococcus. Sometimes the youth of the subject or the delay in treatment may be incriminated. The earlier the injection is given, the better chance there is of saving a child. He advised vaccinating children with the Ramon anatoxin at the end of the first year of life.

Congress of Plastic Surgery

The Société française de chirurgie réparatrice, plastique et esthétique, the founding of which was announced six months ago, held its first congress in Paris, October 3 and 4. Dr. Dartigues, the founder, was to have presided but the evening previous he had been taken to the hospital for an urgent operation. Dr. Aubert of Marseilles, vice president, and Professor Jiano of Bucharest served in his stead. The meeting was attended by about sixty members and guests. Certain practitioners had thought it wiser to be absent, as they had been convicted of having presented photographs of operations, in which traces of dishonest retouching had been discovered with a magnifying glass. The society attaches great importance to the presentation of a program that is honestly scientific and seeks to avoid being invaded by unscrupulous practitioners from certain institutes. Communications on skin grafts, autoplastic operations and the cosmetic improvement of scars made up almost the whole program. Professor Jiano reported in detail the reconstruction of a destroyed nose by the use of the skin of the ring finger, which is left attached to the face for the whole duration of the cicatrization. The results, except for the loss of the little finger, are remarkably good. A scholarly paper was presented by Mr. Auguste Lumière of Lyons on the mechanism of the production of scars. He attributes to purely physicochemical and individual phenomena the disturbance of this process and the formation of keloids. Mr. Gucciardello of Vittoria, Sicily, described a case of reconstruction of a portion of the auricle by means of a reverted mastoid flap. Mr. Wallet read a paper on the radical treatment of hallux valgus and hammer toe. Mr. Bourguet of Paris dealt with the cosmetic surgery of displacements of the eyeball. Mr. Pierre Robin discussed the mode of deformation of the face in the child and in the adult in its relations to glossoptosis and the creation of the too elongated uvula. Mr. Stefani of Nice reported the application of electrocoagulation to the treatment of epithelioma of the eyelids. Dr. Maliniak of New York gave an account of rhinophyma and its complications.

Subsidence of Epidemic of Poliomyelitis

Although it is incomprehensible by what route the transmission occurs, sporadic cases of poliomyelitis are still observed in the remote regions of the primary focus; namely, Alsace. Some observations have been made in Strasbourg that tend to prove the important rôle of germ carriers. One of the suspected carriers is a physician, who is alleged to have established small foci of poliomyelitis among the children of families to which he had been summoned to treat patients with other diseases. The hypothesis that has been advanced in explanation is that the poliomyelitic virus is harbored by a great number of adults —probably in the nasal fossae—without manifesting virulence. Transmitted to young children when the seasonal conditions are favorable, it develops in them in its virulent form, and it is this new form, picked up and carried by the germ carrier, that gives to the disease an epidemic character. A form of prophylaxis has been proposed, which consists in the systematic disinfection, every day, of the nasal fossae, among the whole population—children and adults—of the regions of the area attacked.

Smallpox Vaccination in Paris

A report of Dr. Roux, addressed to the Conseil d'hygiène et de salubrité, of the department of the Seine, announces the results, last year, of the campaign against smallpox in Paris. Not a single case of the disease was notified. The efficacy of the vaccine employed was shown by the results of the primary vaccinations, more than 80 per cent of which "took." A total of 210,990 vaccinations were given, or 15,925 more than in 1928, mostly in the hospitals and maternities and in the public schools. During the year 1929, 42,521 living births were recorded in Paris, with a mortality of a little more than 10 per cent (4,305 deaths) during the first year of life. If from the number of births the number of children who died before the third month is subtracted, these probably not having been vaccinated as yet, there remain 40,108 new-born, 33,366 of which were vaccinated by the public services. To complete this figure, there should be added the primary vaccinations performed at the Hôpital des enfants assistés, where the total number of inoculations was 2,374, without any distinction being made between primary vaccinations and revaccinations. To these numbers should be added the vaccinations of infants performed in the homes, the number of which is unknown. The public services in Paris perform thus three fourths of the primary vaccinations. Few of the new-born in the capital escape vaccination against smallpox. About 4,921 children 11 years of age were revaccinated in the bureaus of charity and in the outpatient department of the hospitals; but almost all the children of that age were reinoculated in the various schools. It is not the vaccination service of the city of Paris that revaccinates the great majority of the men aged 20, but the service of the army medical corps, just before they are enrolled in their regiments. Those who are exempt from military service are nearly all revaccinated, for a recent certificate of revaccination is required of those entering the administrative services, or the trades or industries. The law is well enforced among this class of young men. This is not equally true of the young women of corresponding age. Many of them neglect to present themselves for revaccination. Thus, when an outbreak of smallpox occurs, it is the women who furnish the majority of victims. The number of persons who are not legally obliged to be revaccinated but who are revaccinated in Paris is considerable. In 1929, it amounted to more than 88,000. Two routine revaccination periods are held each year in the schools of the city of Paris, the first on the reopening of the schools, in October or November; the second in May or June. At the second session in May, the children are vaccinated who have entered during the year, together with those in whom the vaccination did not take in October. Not a single case of postvaccinal encephalitis, such as have been observed in other countries, has developed in Paris.

TURKEY

(From Our Regular Correspondent)

Ankara, Sept. 27, 1930.

Antimalaria Work

Communities which the ministry of health and social assistance has declared infected with malaria are obliged to report on all forms of malaria. Military organizations are to carry out antimalaria work conformable to the principles adopted by the ministry of health and are to report on measures taken to the directors of malaria control work or to the health department.

Antitrachoma Work

In communities where trachoma is prevalent, the ministry is to organize antitrachoma committees and establish institutions where treatments and operations are to be carried out gratuitously. Committees organized in trachoma control zones are authorized to register and examine the whole population and have those suffering from trachoma brought to the institution for treatment. Persons suffering from trachoma in the infectious stage are not allowed to attend schools, factories, workrooms or any institutions, governmental or private. In trachoma control zones the ministry of health, together with the ministry of education, is to decide on special measures in regard to school work. Military organizations are to carry out antitrachoma work conformable to the principles adopted by the ministry of health and are to report on measures taken to the health authorities of the community.

Control of Venereal Diseases

Persons suffering from any syphilitic condition are under obligation to seek treatment from a duly authorized physician. The responsibility for the treatment of children rests with the parents or with institutions caring for children. All practicing physicians are at the end of each month to report in writing to the respective departments of health new cases of syphilis, giving name of patient, age and the stage of the disease, and state whether the person has before been treated by a physician. Officials who unlawfully make use of any secret information are liable to punishment. Persons suffering from syphilitic conditions may secure treatment free of charge from a government or municipal physician or at a dispensary. The directors of health and social assistance are authorized to have examined persons suspected of spreading venereal diseases. Such persons are permitted to have themselves examined by a private physician and to present this certificate if they desire. Persons suffering from venereal diseases may be forced to undergo treatment and they may also be forcibly isolated and treated at a hospital if suspected of spreading the disease. If a person suffering from venereal disease is lost sight of without having finished treatment, the attending physician is obliged to send a written information to the respective department of health and social assistance.

All physicians are obliged to provide persons suffering from venereal disease with a leaflet issued by the ministry of health on which the danger of the diseases and routes of infection is explained. In case of a child, information and a leaflet are given to the parents or to a person responsible for the child. Persons knowing that they suffer from a venereal disease who knowingly infect another person are liable to punishment, but this depends on whether a complaint is made. It is prohibited that an infant known to be syphilitic be given to a wetnurse. In communities where a large part of the population is suffering from syphilis, the ministry of health is to organize syphilis control committees and to provide the facilities for treatment. Syphilis control committees are authorized to examine and register the whole population of their respective zone and give treatment to those suffering from syphilis.

In the army, venereal disease control work is to be carried out by special departments. Persons suffering from syphilis in the infectious stage are not released from service until successfully treated. Those who contract syphilis during military service are to have their treatment entered on their records and are reported by the ministry of national defense to the ministry of health.

Antituberculosis Work

The names and addresses of all new cases of tuberculosis of the lung and larynx as well as those of persons having died from any other form of tuberculosis are to be reported. Physicians are to report to the nearest health department all deaths from tuberculosis within twenty-four hours and all new cases within eight days after diagnosis. A physician knowing that a tuberculous person intends to move is obliged to report this to the health department to which the case has previously been reported. The directors of hospitals, maternity hospitals, prisons and all other governmental, charitable or private institutions are to report within twenty-four hours all deaths from tuberculosis.

Physicians may avail themselves free of charge of the services of governmental laboratories where tuberculosis specimens may be sent for examination. On the advice of a governmental, municipal or other attending physician, the home of a tuberculous person may be disinfected free of charge. The ministry is authorized to isolate and treat at a hospital persons suffering from active tuberculosis who are liable to infect others.

Physical Examination Before Marriage

In all men and women intending to get married, a physical examination is required. A regulation is to be published by the ministry of health and social assistance with regard to special points to be considered in such examination. Persons suffering from syphilis, gonorrhea, soft chancre, leprosy or a mental disease are not permitted to get married. Unless they have been scientifically treated and are past the infectious stage or can present a certificate that they are cured, they cannot procure a marriage license.

Marriage is postponed for six months for persons suffering from advanced active tuberculosis. If at the end of that time the condition has not improved, another postponement for six months is to be decided on. At the end of such time the attending physician is obliged to advise both parties as to the danger of the disease and its effects on marriage.

To make sure that wetnurses do not suffer from venereal disease, tuberculosis or leprosy, they are to procure the certificate of a physician. Such certificates have to be renewed every six months. It is prohibited to have women who do not present such a certificate and who do not make any efforts to procure one serve as wetnurses.

Persons selling or serving foods or drinks, and hairdressers, are to have a physical examination every three months and renew the health certificate. If such persons are suffering from syphilis in the infectious stage, active tuberculosis, leprosy or a skin disease they are not permitted to carry on such work. Examinations are to be carried out free of charge by the municipal physician and, in a community where there is none present, by the government physician.

JAPAN

(From Our Regular Correspondent)

Sept. 8, 1930.

Sanitary Commission of Tokyo

When Mr. Nagata, new mayor of Tokyo, met the sanitary commission for the first time after his appointment, Mr. Yuasa, chief of the health section of the city, reported that the tuberculosis patients entrusted to the sanatoriums in the city amounted to 18,250 a year. So the expenditure for the next fiscal year (1931) is to be renewed.

Police Heads in Tokyo Discuss Health Problems

Under the auspices of the metropolitan police bureau, the heads of the police stations in Tokyo held a conference in the bureau, August 18. The sanitary problems discussed by them included house cleaning and disposal of filth; birth control; supervision of the midwives in the prefecture; treatment of trachoma and tuberculosis; public education on the prevention of dysentery, and supervision of barbers and women hair dressers. They decided to lay stress on birth control, agreeing that drugs and appliances to inhibit impregnation or facilitate early abortion methods should be strictly forbidden by police regulations.

The Business Depression and Hospital Fees

Japan has been affected by the depression of business so severely that more than 300,000 persons are out of employment. Some public hospitals, such as the hospital attached to the Osaka Medical College, that of the Osaka branch of the Japan Red Cross Society, and that of the Okayama Medical College, have made a reduction of 10 per cent in the hospital fee and some 20 per cent in the price of medicine. Some medical associations are opposed to the reduction, saying that the hospitals are courting notoriety too much. However, members of the house of representatives from the Seiyukai party, the opposition, as well as those from the Minseito party, are reported as having addressed to the minister of the interior a memorial concerning the reduction of medical fees in general. The hospital of the Shiga branch of the Japan Red Cross Society, at Otsu, is also reported to have decided to make a reduction of from 10 to 15 per cent at the beginning of September.

The Far East Association of Tropical Medicine

To the eighth congress of the Far East Association of Tropical Medicine, which is to be held at Bangkok, Siam, December 7-13, the following delegates have been appointed: Drs. B. Tanabe, imperial Japanese army; Y. Hiki, imperial Japanese navy; N. Onodera, department of education; S. Yamada, government institute for infectious diseases and Keio University. The department of the interior, the Chosen government, and the South Manchuria government will each send a delegate.

First Case of Psittacosis in Japan

A sailor whose birthplace was Nagoya fell ill soon after his arrival at Yokohama, June 17, from America and died at his native place, July 12, after suffering from continual diarrhea and emesis. The case is said to have been the first of psittacosis in this country. The home ministry is reported to be on the point of taking steps to check the importing of parrots from America.

BUDAPEST

The Spread of Trachoma in Hungary

Trachoma had taken root at the beginning of the last century on the boundaries of the country populated by Serbs, Croats, Slovaks and Roumanians. Prior to 1883, scarcely anything had been done to prevent this disease. Attention was called to trachoma by a court of justice. Dr. Feuer was then entrusted to examine the population of three districts, 100,000 persons, and he found that from 4 to 5 per cent of the population had trachoma. It was obvious that trachoma had assumed an endemic form in other parts of the country. The minister of the interior appointed Professor Feuer leader of a campaign, and in 1886 the Hungarian parliament passed a bill, the provisions of which are as follows: 1. Expenses connected with the treatment of indigent patients were to be borne by the state treasury. 2. Where the disease was most prevalent, eye specialists were to be sent to perform the treatment in the larger centers, to organize the treatment of patients in the villages, and to instruct district physicians in methods of treatment. 3. Temporary trachoma hospitals were to be erected. 4. In order to train medical officers, municipal, village and parish physicians in the pathology and therapy of trachoma, the minister ordered that courses of instruction be held in larger centers, and all participating physicians should get adequate remuneration for the duration of the courses in case they had to leave their place of residence. 5. The cost of all these measures were to be defrayed by the state. This law, however, was ineffective, owing to the lack of moral support from the public. In 1912 Professor Feuer died and Professor Emile Grosz was appointed government commissioner. He started with the following program:

1. Continuous observation of all trachoma patients by (*a*) notification; (*b*) examination of eyes in schools, factories and tenements, and of apprentices, domestic servants, demobilized soldiers and recruits; (*c*) general eye examinations of the population, this last measure to be applied exceptionally on the demand of the central authorities.

2. Free treatment in trachoma dispensaries; the medical service to be made by the local physicians, who were to get fixed salaries. The treatment done by these practitioners to be controlled by the district ophthalmologist, who was also the head of the district eye hospital, of about fifty beds.

3. Improvement of hygienic conditions in schools, factories and workshops; the foundation of industrial colonies in the trachoma-stricken districts, in order to check the movement of trachomatous workers, and the supporting of the families of trachoma patients who were incapacitated. Soldiers suffering from trachoma were to be treated in military hospitals. Those cured were to join their regiments.

4. For the advancement of knowledge in the pathology and treatment of trachoma, competitions with attractive prizes. For enlightenment of the public, occasional popular courses.

Professor Grosz's efforts bore fruit. In several cities, special trachoma hospitals, and in existing hospitals, trachoma wards and eye dispensaries were erected until there were 1,200 beds available for trachoma patients. In 1911, twelve trachoma and ninety parish physicians were entrusted with the treatment of patients. He succeeded in persuading the military and civilian authorities to work hand in hand against trachoma. The Conscription act of 1913 contained the provision that those suffering from trachoma, yet otherwise fit for military service, should be placed in a hospital managed by specialists three months prior to the regular time of entrance. Those cured joined their regiments, while those who were incurable were submitted to superior decision at the end of December.

During the late war, the war ministry formed trachoma regiments. The official report of these formations, which, moreover, had been engaged in action, showed that 78.5 per cent were cured, 21.2 per cent still required treatment, and only 0.3 per cent were certified as unfit for military service. Looking forward to the time of demobilization, Professor Grosz adopted extensive precautionary measures. The revolution, however, prevented the execution of those measures. The men of the trachoma wards were scattered and thus carried the disease to areas hitherto immune.

The campaign against trachoma had been successful up to the outbreak of the war. Patients with trachoma were reduced at the dispensary of the Royal Hungarian Ophthalmologic Clinic from 7.2 per cent in 1891 to 2 per cent in 1910. In Torontal County, where every inhabitant was examined in 1883, trachoma was reduced in seventeen years from 4.5 per cent to 1.2 per cent. Of the recruits of the Hungarian army, upward of 2,000 annually were rejected on account of trachoma. In 1924 Dr. J. Brana, surgeon-in-chief of the army, compiled a map on which the soldiers suffering from trachoma were grouped according to the districts to which they belonged. The map showed that the disease was rife throughout the land.

The minister of public welfare felt moved in 1926 to make new inquiries in the schools, institutes, prisons, factories and tenements. The result was that, of 8½ million inhabitants, 10,000 trachoma patients were brought to light. Of 829,284 school children, 3,257 were found to suffer from trachoma. A terrible picture of the spread of trachoma is afforded by two districts in Zala County, where examinations were carried out by reliable specialists. Dr. William Schiller discovered that, out of 3,214 inhabitants examined in one district, 1,247, that is, 39 per cent, were suffering from trachoma. Dr. Lénard found a family in which ten, and another in which eleven, and a third in which eight members were infected with trachoma. These revelations caused the minister to entrust with the treatment competent physicians whose emoluments were insured by the state.

Statistics from the eye clinics show that this evil has taken deep root. In the dispensaries belonging to the eye clinics, the number of trachoma patients in Budapest is 1.5 per cent, in Szeged 10 per cent, in Pécs and Debreczen, respectively, 5 per cent. The difficulty of the situation is shown in the fact that of the trachoma patients examined at the university eye clinic number 1 in Budapest upward of 50 per cent were suffering from pannus, so that the visual power was already endangered. Notwithstanding that the finances of Hungary are weak, the *sum of 81,000 pengö ($16,200) has been appropriated for the* present year for the campaign against trachoma. Besides this, the sum of about 245,000 pengö has been requested in respect of hospital attendance.

There are twenty-two physicians entrusted with the treatment of trachoma, while fifty-nine dispensaries have been founded. In postwar Hungary, there are 1,200 beds available for the treatment of eye patients in university clinics and eye wards, of which 316 are for trachoma patients. The number is entirely inadequate.

The Budapest Royal Hygienic Institute

The Budapest Royal Hygienic Institute, which was opened two years ago, is the best equipped institute in Europe. At present there is an Italian commission of five members making a study of the institute, the intention being to erect a similar one in Italy. Some days ago the Turkish government applied to the Hungarian government requesting it to allow that the director of the institute, Dr. Johann, spend three months in Turkey in order to supervise and direct the new hygienic institute. The Turkish institute was erected in Ankara and it is planned to duplicate the equipment and methods of the Budapest institute. The chief work of the Ankara institute will be the training of medical officers of health. Professor Johann accepted the invitation, and he will shortly leave for Turkey with two assistants.

BERLIN

(From Our Regular Correspondent)

Oct. 6, 1930.

The Meaning of Life

At the recent International Congress of Individual Psychology, held in Berlin, Alfred Adler, the Vienna psychologist, delivered a noteworthy address on "The Meaning of Life." The subject can, of course, be viewed from widely different angles, and often one may even be inclined to ask whether life has in reality any meaning. One of the possible solutions is found in the fact that many persons base their hopes on a better world beyond the grave. "Individual psychology" interprets the meaning of life in a definite manner and bases on its interpretation conclusions of a practical nature. Individual psychology starts with the assumption that every human being has a life plan, a trend and a final objective peculiar to himself, although the individual himself may be unconscious, or only partly conscious, of the fact. The chief purpose of man is, then, to make this life plan a reality and to attain that final objective. The instinctive desire for such a realization is, however, often restricted by family and social considerations and also by bodily conditions. A sense of powerlessness in the face of unfavorable conditions may easily give rise to feelings of inferiority, which will serve to check one's development and hamper the realization of the life plan. In endeavoring to compensate for this inferiority, the individual comes into conflicts with himself and his environment. If one examines from this point of view children who are hard to manage and to educate, neurotics, persons mentally abnormal, criminals, suicides and sexual perverts, there is frequently found a lack of what Adler terms "community sense," or interest in the common welfare of their community. Any one lacking this sense, or this quality, is unable truly to solve the problems of life. The inner mental capacities of the individual can be developed only as capacities possessed in common with other members of the community and only in cooperation with the community. The "ego" in its thousand variations is differentiated chiefly by the degree of community sense. Therein lies the most profound meaning of life.

One chief purpose of individual psychology is to prevent the person born with inferior vital organs from becoming an invalid or a neurotic, and to show that the person afflicted with social impairments need not follow an asocial or antisocial course. In other words, to convert asocial tendencies into social aspirations is the task, or, expressed in terms of individual psychology, to encourage the discouraged and to aid in overcoming the resistance in the organism and the obstacles of one's surroundings and environment. It has been proved that, working from the principles of individual psychology, good success may be achieved in the training of children who are recognizably hard to manage. But it is difficult to apply this therapeutic art and not every one has the capacity for it. There are no logical, mathematically exact solutions, and Adler does not assume to possess any infallibility in the application. A cure can be effected only through bringing the subject into a state of reconciliation with the problems of life; that is, by causing him to recognize the aberrant nature of his aims in life and by strengthening the community sense, two important manifestations of which are the courage to live and the making of contributions for the general weal. A cure can be effected only through application of the principle of "Know thyself," for which, however, individual psychology, with its artistic technic, though not easily understood and not easily applied, constitutes an excellent guide.

The Heidelberg Orthopedic Congress

The jubilee congress of the Deutsche orthopädische Gesellschaft, held in Heidelberg recently, was well attended by German and also foreign physicians. Professor von Baeyer, the chairman of the society, opened the session with an address in which he gave an interpretation of the term "orthopedics." He stated that "orthopedics" has as its objectives the prevention, the detection and the treatment of enduring functional disturbances of the motor apparatus. An anniversary address was delivered by the Heidelberg pathologist Ernst on the subject "Structure and Function." Spitzy of Vienna presented a paper on the pathologic motor disturbances of the arm, and Steindler of Iowa discussed arm paralyses. Among the large number of papers presented, special interest is attached to that of Böhm of Berlin on "Explanation of Certain Defective Forms of the Legs" and that of Schrader of Heidelberg on "Principles of Mechanical Treatment in Orthopedics." Professor Ludloff of Frankfort discussed treatment of tuberculosis of the bone. Hohmann of Frankfort proposed a resolution that was unanimously adopted to the effect that—in view of the war injured, state aid for cripples, the prevention of bodily injuries in the oncoming generation, and the provision of bandages and prostheses for persons injured in accidents—orthopedics should be made one of the subjects in which, according to the new program for medical examinations, candidates for the degree of doctor of medicine must be examined.

Is Social Aid Exaggerated?

One hears, of late, such questions as these: Under the present conditions of universal stress, does not social aid with relation to public health take on an exaggerated character? Does it accomplish what its champions claim? Does it not weaken the feeling of self-reliance? Does it not tempt many to take refuge in the perception of some personal pathologic condition? At a recent session of the society Soziale Krankenhausfürsorge, Professor Gottstein, retired "ministerial director," gave his personal reactions to some of the foregoing questions. Since its foundation in 1916, this society has given aid to nearly 5,000 persons in the university clinics of Berlin. Gottstein would not admit that the questions cited were more than partially justified—in the main they are exaggerated. He rejects them, however, entirely as far as social aid to hospital patients is concerned. The movement is purely social to the extent that it takes an interest in the economic conditions of the hospital inmates and supplies aid when needed. But its interest in social hygiene goes further than that and it must develop more in this direction by combining with the aid given in the hospital the aid needed after dismissal, in order that gains made in the hospital may be preserved, recurrences may be prevented and the earning capacity remain unimpaired. This applies more particularly to patients under treatment for malignant tumors, tuberculosis, venereal diseases, and mental disturbances, but also to patients with diabetes and to many persons with gastrointestinal disorders.

The society furnishing aid to hospital patients must give help to the physician and to the nurse in the hospital and support them in their respective tasks. More and more, the sick-bed is migrating from the individual home to the hospital, while treatment is carried on more on the wholesale plan. Under no circumstances must the patient in the hospital be allowed to become effeminated. Cooperation in carrying out occupational therapy is one of the important tasks of the movement. The recent development of the movement has been so much in the direction of health care that it must be taken out of the realm of the welfare authorities and placed in the hands of the health authorities.

After the patient is dismissed from the hospital, social aid for hospital inmates must be applied in accord with the attending physician. It must take the form of direction and of instruction. The patient must himself recognize the fact that, after dismissal from the hospital, he must submit to observation. The workers of the society must endeavor to awaken in him a feeling of self-reliance and an understanding of the needs of the situation, in order that he may come to recognize his own responsibility and his duty to preserve his health in the interest of himself and of the community.

Light as a Defense Against Disease

The main assembly of the Deutsche Gesellschaft für Gewerbehygiene was held recently in Breslau. During the course of the eventful session, which was attended by some 600 members and guests from Germany, Austria, the Saar region, Danzig, Switzerland, Hungary, Jugoslavia, Czechoslovakia, Poland, Japan and other countries, many papers were presented dealing with the hygienic conditions that must receive consideration in the building of homes and the planning of cities, and also in the organization of industrial plants and in the laying out of offices.

Of especial interest for a larger circle were the words of Prof. Dr. von Drigalski, "stadtmedizinalrat" of Berlin, on the topic "Labor and Dwelling." He called attention especially to the danger of the bacterial content of the air. In the light of present knowledge, it is by no means an heroic experiment to take a deep breath over soil inoculated with cholera bacilli, for bacilli are to be found in the liquids. The large number of relatively harmless causative agents of inflammation contained in the "living dust" of the air is evidently the source of many inflammations of the throat, to which man pays little attention, but also of many rheumatic infections. He demanded an extension of research from the field of rheumatism to that of sore throat. Even if no acute disorder develops, the organism is severely taxed by its constant struggle with the causative agents and is thus weakened in its resistance.

The best means of defense, he said, was light and light surroundings, rooms with white walls. The chemical action of light is underestimated. Whereas red, yellow and, to a certain extent, green light exert chiefly a warming effect, the short-waved rays, toward the direction of the violet, are more chemically active. It was formerly the supposition that the chemical action of light is confined to the skin—that it does not penetrate the deeper layers. Investigations have proved the assumption false. The tanning of the skin by the sunlight is more than a mere "beauty aspect"; it effects a strong stimulation of the circulation and thus also of general metabolism. The chemical action of bright sunlight in living rooms becomes evident through the fact that the bacterial content of the air is thereby considerably diminished or even entirely eliminated.

In addition to the stimulation of light, the so-called work stimulation is important for the preservation of health. Idle tissues not only do not develop but even atrophy. The most favorable frontage for isolated houses is toward the north, since the rooms toward the east and also the rooms toward the west have the sunlight for half a day. The living rooms must by no means be impaired by the use of unsuitable paint and decorations.

Marriages

August L. Fipp, Glandorf, Ohio, to Miss Marie Lillian Bause of Hollywood, Calif., in Ferrin Park, Wis., October 14.

Ben Hamilton Nicholson, Nashville, Tenn., to Miss Winifred Tucker of Tintah, Minn., September 2.

David C. Morton, Louisville, Ky., to Mrs. Elizabeth Booker Williams of Richmond, Va., September 11.

Duncan Bruce Wiley, Utica, Mich., to Miss Lorraine LaCroix of Mount Clemens, September 17.

Archibald Murdoch McKeithen, Louisville, Ky., to Miss Louise Wheat Bulkeley, August 15.

Robert H. Durham, Detroit, to Miss Mary Louise Edwards of Sileo City, N. C., September 3.

George L. Perusse, Jr., Chicago, to Miss Henrietta Bird of Wilmette, Ill., September 30.

William E. Range, Collinsville, Ill., to Miss Grace Hallworth, September 14.

Milton H. Seifert, Sherburn, Minn., to Miss Laura Dupont, May 31.

William Philpot, Augusta, Ga., to Miss Mary Bowles, July 14.

Deaths

John Aloysius Ceconi ⊕ Boston; Tufts College Medical School, Boston, 1904; director of medical inspection in the Boston public schools; formerly medical inspector, diagnostician, epidemiologist and director of the bureau of communicable diseases, Boston Health Department; served during the World War; aged 49; died, September 21, in the City Hospital, of cholelithiasis and myocarditis.

Elizabeth L. Peck ⊕ Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1885; member of the American College of Surgeons; for many years on the staff of the West Philadelphia Hospital for Women, and the Philadelphia General Hospital; aged 75; died, September 30, of carcinoma of the breast.

Ethelbert Hines Galloway, Jackson, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1903; member of the Mississippi State Medical Association and the American College of Surgeons; on the staff of the Mississippi Baptist Hospital, where he died suddenly, August 26, of heart disease, aged 50.

Isaac G. Shallcross, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1887; member of the American College of Surgeons; professor emeritus of rhinology and laryngology at his alma mater; on the staff of the Hahnemann Hospital; aged 68; died, September 21, of angina pectoris.

Robert Harold Morris, Kansas City, Mo.; Barnes Medical College, St. Louis, 1896; Tulane University of Louisiana School of Medicine, New Orleans, 1914; member of the Missouri State Medical Association; served during the World War; aged 54; died suddenly, August 24, of cerebral hemorrhage.

Paul Kreye, Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1883; aged 76; formerly on the staffs of the Cook County Hospital, Columbus Hospital, St. Joseph's Hospital and the American Hospital, where he died, September 17, of tumor of the left lung and arteriosclerosis.

Robert Nebinger Meisenhelder, Hanover, Pa.; Jefferson Medical College of Philadelphia, 1871; member of the Medical Society of the State of Pennsylvania; aged 84; on the staff of the Hanover General Hospital, where he died, August 20, of injuries received when struck by an automobile.

John Paul Benson, Joliet, Ill.; Rush Medical College, Chicago, 1902; member of the Illinois State Medical Society; served during the World War; on the staffs of the Silver Cross Hospital and St. Joseph's Hospital; aged 53; died suddenly, September 12, of cerebral hemorrhage.

Thomas Jefferson Proffitt, Elk Park, N. C.; University of Louisville (Ky.) School of Medicine, 1903; member of the Medical Society of the State of North Carolina; aged 57; died, September 23, in the Grace Hospital, Banner Elk, of injuries received in an automobile accident.

John Edwin Hays ⊕ Louisville, Ky.; Hospital College of Medicine, Louisville, 1880; at one time professor of anatomy and dermatology at his alma mater; formerly on the staff of the City Hospital; aged 71; died, September 20, of coronary thrombosis and myocarditis.

Emily Frances Pope, Boston; New England Female Medical College, Boston, 1870; member of the Massachusetts Medical Society; for many years on the staff of the New England Hospital for Women and Children; aged 84; died, August 28, of cardiorenal disease.

Henry C. Mitchell, Carbondale, Ill.; Chicago Medical College, 1879; member and past president of the Illinois State Medical Society; member of the American College of Surgeons; aged 74; died, October 2, in a hospital at Jacksonville, of arteriosclerosis.

Lewis Van Gilder Guthrie ⊕ Huntington, W. Va.; College of Physicians and Surgeons, Baltimore, 1889; member of the American Psychiatric Association; superintendent of the Huntington State Hospital; aged 62; died, September 20, of chronic nephritis.

Arlington Pond ⊕ Cebu, P. I.; University of Vermont College of Medicine, Burlington, 1895; veteran of the Spanish-American and World wars; served in the U. S. Public Health Service; aged 57; died, September 19, following an operation for appendicitis.

Clarence Edward Kinley, Costa Mesa, Calif.; Hahnemann Medical College of the Kansas City University, Kansas City, Mo., 1901; formerly professor of pediatrics, Kansas City Hahnemann Medical College; aged 52; died, August 5 of diabetes mellitus.

Henry S. Beers, New York; Bellevue Hospital Medical College, New York, 1887; member of the Medical Society of the State of New York; on the staff of the Harlem Hospital; aged 73; died suddenly, September 6, in Kenoza Lake, of myocarditis.

Joseph Monroe Stanley, Banks, Ala.; University of Tennessee College of Medicine, Memphis, Tenn., 1909; member of the Medical Association of the State of Alabama; aged 43; died, August 29, in a hospital at Troy, of intestinal obstruction.

Joseph Solomon Lieb, Brooklyn; Long Island College Hospital, Brooklyn, 1920; on the staff of the Brownsville and East New York Hospital; aged 32; died, September 13, in the Mount Sinai Hospital, New York, of acute leukemia.

George Tancrede Lamarche, Putnam, Conn.; University of Montreal Faculty of Medicine, Montreal, Que., Canada, 1887; member of the Connecticut State Medical Society; aged 66; died, September 14, of chronic myocarditis.

John N. Hess, New Marion, Ind.; Medical Department, University of Tennessee, Nashville, 1881; member of the Indiana State Medical Association; formerly county coroner; aged 76; died, in September, of pneumonia.

Dorsey Paul Etzler, Woodsboro, Md.; University of Maryland School of Medicine, Baltimore, 1915; served during the World War; aged 40; died, in September, at Blue Ridge Summit, Pa., of pulmonary tuberculosis.

Elmer W. Cashman ⊕ York Springs, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1886; president of the bank, town council and school board; aged 69; died, September 6, of cerebral hemorrhage.

Albert W. Reddish, Sidney, Ohio; Homeopathic Hospital College, Cleveland, 1883; member of the Ohio State Medical Association; formerly member of the school board; aged 70; died, in September, of heart disease.

William F. McManus, Chattanooga, Tenn.; Medical Department, University of Tennessee, Nashville, 1897; formerly county physician and president of the board of health; aged 65; died, September 11, of myocarditis.

Robert Boyd Andrews ⊕ Belvidere, Ill.; Chicago Homeopathic Medical College, 1896; past president of the Boone County Medical Society; served during the World War; aged 57; died, August 15, in St. Joseph's Hospital.

Louis Irving Mason ⊕ Willimantic, Conn.; Medical Department of Columbia College, New York, 1891; served during the World War; on the staff of St. Joseph's Hospital; aged 64; died, September 29, of pneumonia.

Henry K. Du Bois, Port Orange, Fla.; Bellevue Hospital Medical College, New York, 1870; member of the Florida Medical Association; formerly mayor of Port Orange; aged 83; died, September 9, of nephritis.

H. Valentine Wildman, Sr., New York; University of Michigan Medical School, Ann Arbor, 1880; consulting neuropsychiatrist to the U. S. Veterans' Bureau; aged 72; died, September 24, of heart disease.

Edward Wilbur Vis ⊕ Grand Rapids, Mich.; Grand Rapids Medical College, 1903; served during the World War; aged 49; died, September 19, in a hospital at Waukesha, Wis., of aortic and mitral stenosis.

John Jay Farley, Belleville, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1873; M.R.C.S., England, 1874; for many years county jail physician and coroner; died, June 28.

Isham Edgar Perkins, Jackson, Tenn.; Vanderbilt University School of Medicine, Nashville, 1891; aged 60; died, September 20, in the Crook Sanitarium, of chronic nephritis and myocarditis.

Charles Elliot Thompson, Los Angeles; Cooper Medical College, San Francisco, 1894; member of the California Medical Association; formerly health officer of Dunsmuir; aged 60; died, July 25.

Newton L. Moore, Palmer, Texas; Medical Department, University of Tennessee, Nashville, 1890; member of the State Medical Association of Texas; aged 70; died, August 26, of heart disease.

Clarence Joseph Shafer, Norwood, Ohio; University of Cincinnati College of Medicine, 1921; aged 34; died, September 20, in the Good Samaritan Hospital, of acute hemorrhagic pancreatitis.

Edward Burtson Kellogg ⊕ Ypsilanti, Mich.; Michigan College of Medicine and Surgery, Detroit, 1901; aged 54; died, September 18, of acute suppurating sigmoid diverticulitis and peritonitis.

Philip Henry Killey, Vivian, W. Va.; Medical College of Virginia, Richmond, 1872; member of the West Virginia State Medical Association; aged 81; died, September 1, of acute uremia.

William Paul Tebault, New Albany, Ind.; College of Physicians and Surgeons, Baltimore, 1883; member of the Indiana State Medical Association; aged 65; died, September 26.

Robert Lee Crawford, Miami, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1912; served during the World War; aged 40; died in August in Havana, Cuba.

Robert Malone King, Wyoming, Ill.; Louisville (Ky.) Medical College, 1898; member of the Illinois State Medical Society; aged 66; died, September 22, of heart disease.

Frank Louis Hodges, Monroe, Wis.; Rush Medical College, Chicago, 1900; member of the State Medical Society of Wisconsin; aged 59; died, September 4, of pneumonia.

Ole Mork, Blair, Wis.; King Fredericks University Faculty of Medicine, Oslo, Norway, 1900; member of the State Medical Society of Wisconsin; aged 56; died, August 2.

Frederick William Comings, Eugene, Ore.; University of Vermont College of Medicine, Burlington, 1886; aged 72; died, July 3, in Salem, of chronic myocarditis.

Charles Wessales Brodhead, Palisades Park, N. J.; New York Homeopathic Medical College and Flower Hospital, 1912; aged 46; hanged himself, September 3.

William Wright Milligan ⊕ Burlington, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; aged 64; died, September 19, in a local hospital.

John J. Lancaster, Trezevant, Tenn.; Medical Department, University of Tennessee, Nashville, 1898; aged 67; died, September 21, of carcinoma of the lung.

Asahel Wesley James, San Diego, Calif.; Rush Medical College, Chicago, 1899; aged 62; died, in September, of an overdose of narcotics, self-administered.

Oscar P. Schaub ⊕ Winston-Salem, N. C.; Baltimore Medical College, 1898; aged 57; died, September 8, in a local hospital, of cerebral hemorrhage.

John H. Talbott, Hollywood, Fla.; Indiana Medical College, Indianapolis, 1875; aged 79; died, September 18, in Forest Hills, N. Y., of angina pectoris.

R. Furman Divver, Anderson, S. C.; Philadelphia University of Medicine and Surgery, 1868; aged 89; died, September 14, of cerebral hemorrhage.

Charles H. Stimson ⊕ Newark, Ohio; Bellevue Hospital Medical College, New York, 1879; aged 80; died, September 13, of pernicious anemia.

Luther W. Bell, Schoolfield, Va.; Memphis (Tenn.) Hospital Medical College, 1909; aged 48; died, September 21, in Danville, of cholelithiasis.

Edward Cook ⊕ Bellport, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1904; aged 51; died, September 7.

Warren H. Willyard, Kokomo, Ind.; Kentucky School of Medicine, Louisville, 1907; aged 66; died, September 24, of carcinoma of the liver.

Adam Fuhrmann, St. Louis; St. Louis Medical College, 1876; aged 76; died, September 8, in the Lutheran Hospital, of mesenteric thrombosis.

Daniel W. Bottorf, Astoria, Ill.; Missouri Medical College, St. Louis, 1899; also a dentist; aged 71; died, September 13, of heart disease.

Ira Lee Goodwin, Lake Providence, La.; Memphis (Tenn.) Hospital Medical College, 1910; aged 45; died, in August, of chronic myocarditis.

Lauren Jones, Daytona Beach, Fla.; Lincoln (Neb.) Medical College, 1908; aged 64; died suddenly, September 6, in Waynesville, N. C.

Helen Watson Winternitz, New Haven, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1910; aged 45; died, April 25.

H. Hennerich Groth, Dayton, Ohio; Hahnemann Medical College of Philadelphia, 1879; aged 82; died, September 25, of arteriosclerosis.

Benjamin F. Edgington, Warren, Ind.; Curtis Physio-Medical Institute, Marion, 1889; aged 80; died, September 13, of heart disease.

John Lafayette Harrison, Winnsboro, S. C.; Atlanta College of Physicians and Surgeons, 1912; aged 54; died, August 30.

Bureau of Investigation

SANOVAPOR

Another Cure-All of the Liquozone Type

Sanovapor Laboratories, Inc., of Huntington, W. Va., put out a nostrum, Sanovapor, that is recommended for such conditions as: Catarrh, colds, hay fever, asthma, bronchitis, tonsillitis, sore throat, stomach, liver, kidney and bowel disorders, diseases of women, pyorrhea, gastritis, gastric ulcer, diabetes, Bright's disease, high blood pressure, piles, cuts, scalds, burns, wounds, sprains, abrasions, insect stings, old sores, boils, carbuncles, abscesses—and halitosis!

The therapeutic *modus operandi* of Sanovapor has been thus described:

> "SANOVAPOR sterilizes the blood and vitalizes it; it neutralizes the poisons and enables the poisons to pass through the bowels, kidneys, lungs and skin, the four channels of elimination.
>
> "SANOVAPOR gives to the blood an additional amount of the same *elements obtained by the atmosphere through the lungs.* When SANOVAPOR *is used nothing injurious remains in the system.*
>
> "SANOVAPOR stimulates healthy cell growth, causing unhealthy tissue to be thrown off, then eliminated through the system. It has a permanent value to the entire body through its tonic action."

The advertising matter also goes into detail regarding what is described as the "Specific Action of Sanovapor," thus:

> "*First action:*—SANOVAPOR penetrates the air passages—nose, mouth, throat, sinuses, Eustachian tubes in the ears, bronchial tubes and lungs, from lungs into blood-stream by inhalation.
>
> "*Second action:*—When swallowed SANOVAPOR enters Alimentary canal, or gastro-intestinal tract, consisting of mouth, gullet, stomach, appendix, small and large intestines, rectum to anus.
>
> "*Third action:*—SANOVAPOR reaches every part of the body through the blood-stream."

Especially does Sanovapor seem to be pushed as a remedy for diabetes. Like practically every other "patent medicine" sold for this condition, the exploiters emphasize the fact that the patient must carefully diet. Where this is done, the Sanovapor, of course, could be poured down the sink and equally good—or better—results obtained.

Because of the inquiries that have came in to the Bureau of Investigation regarding this product, an original specimen of Sanovapor was submitted to the A. M. A. Chemical Laboratory with the request that some analytical work be done on the product. The Laboratory report follows:

LABORATORY REPORT

"One original bottle of Sanovapor (Sanovapor Laboratories, Inc., Huntington, W. Va.) was submitted to the A. M. A. Chemical Laboratory for examination. The bottle contained 475 cc. (approximately one pint) of a lemon-yellow liquid of a pungent odor and bitter taste, and possessing a specific gravity of 1.0016 at 25° C. Qualitative tests indicated the presence of sulphur dioxide, sulphate, and a yellow coloring material. Chlorides and heavy metals were not found.

"Quantitative determinations yielded the following:

Total solids	0.095 per cent
Sulphur dioxide (SO_2)	0.064 per cent
Sulphate ($SO_4{=}$)	0.157 per cent
Total acidity after oxidation with hydrogen peroxide	1 N x 0.0585

"Those values may be calculated to:

Sulphuric acid	0.16 per cent
Sulphur dioxide[1] (calculated to sulphurous acid equivalent to 0.08 per cent)	0.06 per cent

"From the foregoing, it appears that this product consists essentially of a solution containing approximately 0.06 Gm. of sulphur dioxide and 0.17 Gm. of sulphuric acid, U. S. P., in 100 cc., and possessing a yellow color."

It is evident from the chemists' report that Sanovapor is yet one more imitation of the old Radam's Microbe Killer Many years ago, Radam's Microbe Killer, which emanated from New York City, consisted of a trifling amount of sulphuric acid and sulphurous acid, in water to which was added a little red wine. Twenty-five years ago when it was being pushed in the United States, the exploiters had dispensed with the wine (which merely added to the cost) and the stuff was reported by Dr. Harvey W. Wiley, on the basis of an analysis made by the federal chemists, to have the following composition:

"Sulphuric acid	0.59 per cent
"Sulphurous acid	0.016 per cent
"Inorganic matter	0.013 per cent
"Water by difference	99.381 per cent"

Radam's Microbe Killer was repeatedly declared misbranded under the national Food and Drugs Act, but like all medical fakes, *continued to flourish so long as the public was ignorant* of the facts and newspapers could be found to carry the advertisements.

Out of the ashes of Radam's Microbe Killer, there arose a similar product, exploited from Chicago under the name Liquozone. This preparation was recommended for fifty-seven varieties of human ailments, ranging alphabetically from asthma, blood poison, cancer, consumption and goiter to leucorrhea, malaria, rheumatism and throat trouble. Liquozone was analyzed and reported to have the following composition:

Sulphuric acid	0.9 per cent
Sulphurous acid	0.3 per cent
Water	98.8 per cent

Then, there was Septicide, a Milwaukee nostrum, which was recommended for practically everything from cancer to "sweaty feet." When analyzed by the government chemists, it, also, was *found to consist of small quantities of sulphur dioxide* and sulphuric acid in water!

Then came Oxytonic, which like its predecessor, Liquozone, also hailed from Chicago. It was advertised as a "tonic germicide" for internal and external use. This preparation, according to the analysis of the state chemists of North Dakota, contained:

Sulphurous acid	0.13 per cent
Sulphuric acid	0.16 per cent
Water to make	100.00 per cent

Following Oxytonic, there was Zymatoid, exploited from Rockford, Ill., and described as an "antiseptic, germicide and antiphlogistic," which had "absolutely no peer in medicine." Analyzed in the A. M. A. Chemical Laboratory, Zymatoid was found to be one more weak solution of sulphur dioxide and sulphuric acid in water!

After Zymatoid had faded from the picture, there came Anti-Phymin, put out, first of all, from Attica, Ind., and later from Pensacola, Fla. It, too, was recommended for practically the whole gamut of human ailments. The A. M. A. Laboratory reported that Anti-Phymin was a dilute solution of sulphurous acid and sulphuric acid in water!

And now Sanovapor. One of the outstanding features of nostrum exploitation is the lack of originality!

The New Physics.—Confidence in the uninterrupted order of law in the course of natural phenomena is based, after all, upon only modest successes achieved by human research in the intellectual coordination of natural events. This confidence has, therefore, no absolute character. Even today many are influenced by a feeling of opposition to the postulate of any unbroken order of laws. It is not easy for us to look upon our acts of will as dependent upon strictly causal sequence and to waive our faith in the spontaneity of our actions. "We can indeed do as we *like*, but we are compelled to like what we must do" means a bitter pill for proud man. . . . Despite our conviction that practical life cannot get along without the fiction of a free will, the doctrine of uninterrupted causality is in no serious danger of a threat on the part of philosophic psychology. Especially, experiences concerning the action of internal secretions, of hypnosis, and of certain poisons upon psychic reactions, have had the effect of fairly well silencing opposition from that quarter Today faith in unbroken causality is threatened precisely by those whose path it *had illumined as their chief and* unrestricted leader at the front, namely, by the representatives of physics—Einstein, Albert: The Drift of Civilization: A Symposium, New York, Simon and Schuster, Inc, 1929.

---

[1] When sulphur dioxide is dissolved in water, it forms an equilibrium mixture of sulphurous acid and sulphur dioxide. $SO_2 + H_2O \rightleftharpoons H_2SO_3$

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

DIABETES AND PREGNANCY — STERILITY

To the Editor:—1. I have a patient with diabetes mellitus, a woman, aged 30, whose blood sugar ranges from 160 to 250 mg. per cubic centimeter with no sugar in the urine at this level. She is on a moderate diet, without insulin. She would like to have a child. Would it be safe for her to go through a confinement if she goes on insulin and keeps the blood sugar within normal limits? 2. Another patient, aged 38, is desirous of having a child. She has been curetted and has been on various glandular preparations. Both she and her husband appear healthy and normal, but no pregnancy has taken place. Please advise what else should be done. Please omit name and address. M.D., Kansas.

Answer.—1. A large proportion of women with outspoken diabetes mellitus are sterile and many diabetic women who become pregnant have abortions or premature labor. Formerly true diabetes had an unfavorable effect on pregnant women because a large number of them died. Nowadays many women with diabetes are successfully carried through pregnancy with the aid of insulin, but in some diabetic patients death results in spite of insulin. In the case cited, the patient should be advised to try to become pregnant. If she conceives, a careful control of her urine and blood sugar and the use of insulin if necessary will most likely enable her to go through gestation without any harm.

2. The statement is made that both the patient and her husband appear healthy and normal but tests should be made to make certain of this. First the husband's sperm should be examined. The sperm may be obtained in a small wide-necked jar or bottle or, better still, from the vagina after natural intercourse. If the latter method is chosen, the patient should be instructed to insert a piece of cotton into the vagina after coitus and go to the physician's office immediately so that the examination may be made as soon as possible. The simplest way to secure the sperm from the vagina is by means of a pipet. If the sperm is normal, a careful physical examination should be made of the patient. When making a pelvic examination, one must not omit using a speculum. If cervicitis is present it can be detected more certainly by inspection than by palpation. Not infrequently a cervical infection is the cause of sterility and it is usually easy to cure by means of an electrical cautery. If the sperm is normal and the pelvic examination fails to reveal any abnormalities, a Rubin tubal patency test should be performed. This test is followed by pregnancy in many instances. A curettement for sterility should not be done until it has been shown that the tubes are patent. Glandular preparations except perhaps thyroid are seldom effective in overcoming sterility.

INTOXICATING EFFECT OF ACETYLSALICYLIC ACID AND COCA COLA

To the Editor:—The young people of this community are using from 15 to 20 grains of aspirin dissolved in the well known soft drink Coca Cola as an intoxicating beverage and seem to get a result very closely resembling that from alcoholic beverages. Can you explain the mechanism of the intoxication? Will the continued use result in physical impairment and, if so, what may we expect?

E. L. Roberts, M.D., Cissna Park, Ill.

Answer.—The effects are due chiefly to central depression caused by the acetylsalicylic acid (aspirin), fortified possibly by a direct central stimulant action of caffeine and other constituents present in Coca Cola. Acetylsalicylic acid is known to exert a more powerful central depression than sodium salicylate because of the presence of the acetyl group. For this reason, acetylsalicylic acid is extensively employed by the laity as an analgesic, in the relief of headache, neuralgia and so on, and as an hypnotic. The actions of this drug are similar to those of small doses of alcohol, or of a weak alcoholic beverage, or of the barbitals or bromides. In definitely effective, but not paralytic, doses the effects are characterized by removal of central nervous inhibition, thus causing loss of self-control, laughter, dreams, abolition of pain and distress, general excitation, increased heart rate, and flushing of the skin; in short, the typical effects of a narcotic drug. Acetylsalicylic acid is not an unpleasant drug to take, and when taken with a beverage like Coca Cola, advertised for its exhilarating effects, which may be caused by a direct central stimulation by caffeine or other constituents, it is easy to see how the effects of one can be fortified by the other. For instance, a function now unopposed, because of the removal of inhibition by acetylsalicylic acid, is driven harder and faster than before.

The continued use of such a medicated beverage can result in undesirable effects, of the same general nature as those of narcotic habituation. These may be manifested by one or more of the following symptoms: nervousness, irritability, apprehension, insomnia, loss of appetite, cardiac irregularity, anemia, loss of body weight, diminished resistance, increased susceptibility to colds and to infections in general; or, in other words, a general impairment of health and character and all that this connotes. There is no doubt of positive dangers from the widespread use of such a medicated beverage, especially among the young. Here is a most insidious evil—the reenforcement of a popular and highly advertised beverage by a well advertised drug, both long suspected of dangerous tendencies. When opiates and cocaine went their way, then came the barbitals. Two states (California and Virginia) have already enacted legislation against the free dispensing and prescribing of these newer narcotics. The indiscriminate or illicit use of acetylsalicylic acid may cause similar restriction.

BURNING OF ROOF OF MOUTH FROM ARTIFICIAL DENTURE

To the Editor:—I have a patient who had two teeth extracted in the upper jaw in front. The permanent bridge was placed two weeks later. In a day or two following this, the patient started with burning in the roof of the mouth, mostly anteriorly, of a severe and annoying character. Many trips to her dentist followed and the two tooth bridge was cut apart without relief of symptoms. She went to another dentist, who blamed the bridge and removed it, with one tooth on each side of the bridge. A rubber denture of four teeth was made covering most of the roof of the mouth, with no amelioration or symptoms. At this time I sent her to a neurologist, who found everything normal and suggested a removal of the denture for such length of time to stop the symptoms, which took one week. The denture was then replaced and symptoms returned the same day. I had the dentist roentgenograph the upper jaw and the surrounding teeth, but nothing pathologic was found. I also had the dentist cut away as much rubber as possible from touching the roof of the mouth, and this brought no results. Salivation was always an annoying symptom and still is. The first teeth were removed two years ago and the other two one year ago. Can you tell me anything that can be done to relieve these symptoms and still give the patient biting surfaces? B. A. Braude, M.D., Johnstown, Pa.

Answer.—If a new bridge, which does not press on the gum tissue, can be made for this patient, she should have no further trouble. If she was comfortable after the denture had been out for a week, there appears to be no reason why there should be discomfort from wearing a "fixed" bridge—a bridge permanently attached to the two upper cuspid teeth.

INTERFERENCE WITH PREGNANCY COMPLICATED BY PHLEBITIS

To the Editor:—Mrs. W., aged 39, the mother of three children, the youngest of whom is 6 months of age, developed a phlebitis in both limbs after the last birth, and is not yet back to normal. The general health is fair and the blood picture normal. The patient is now six weeks pregnant and I am inclined to produce an instrumental termination. Would this possibly make a subacute phlebitis acute? Will leaving it alone be the better course? S. L. Weisbrod, M.D., Milford, Mich.

Answer.—Since only six months has elapsed from the time of onset of the phlebitis, it may be hazardous to do anything that may stir up the phlebitis. Since the phlebitis was bilateral, the infection must have been fairly extensive. There would be a distinct risk in performing an instrumental abortion at the present time. It is safer to allow the pregnancy to continue to term and have a normal delivery. Even at that time there will be some danger of a recurrence of the phlebitis, but it will probably be far less than instrumental interruption of pregnancy at the present time.

ESTIMATION OF BLOOD UREA — VEHICLES FOR THE DISPENSING OF ACETYLSALICYLIC ACID AND PHENOBARBITAL SOLUBLE

To the Editor:—1. Please give me the technic for estimating blood urea by titration with mercuric chloride and a comparison as to accuracy with a colorimeter method. 2. What is the best vehicle for acetylsalicylic acid? 3. What is the best vehicle for phenobarbital sodium? I dispense quite a bit of these drugs and have trouble getting it into solutions. Kindly omit name. M.D., Georgia.

Answer.—1. A paper on "Apparatus for the Determination of the Salivary Urea Index" was described by Hench and Aldrich (The Journal, April 12, 1924). The same authors published a paper on "Urea Retention: A Simple Method for Its Estimation by the Mercury Combining Power of Blood" (*Arch. Int. Med.* **38**:474 [Oct.] 1926). The principle of the method described by Hench and Aldrich was employed by Liebig in 1853. Owing to the fact that the method is not strictly accurate, it has been of little use in recent years. Hench and Aldrich have shown, however, that there is a definite parallelism between the figures for the mercury combining power of the blood and the urea and nonprotein nitrogen and point out how figures for urea may be roughly calculated. The LaMotte Chemical Products Company of Baltimore manufacture the Hench and Aldrich blood urea outfit, which has been graduated to read directly the number of milligrams of urea per hundred cubic centimeters of blood. Directions are supplied with the outfit. While this method will probably give reasonably reliable information regarding the level of the blood urea, it is not sufficiently less complicated than quite a number of methods which give accurate figures for the urea nitrogen of the blood to be given preference over these methods. Owing to its greater simplicity in the case of saliva, there would seem to be some reason for its use there.

2. Acetylsalicylic acid should not be dispensed in a vehicle unless it is taken shortly after preparation. In this instance, it may be dissolved in a mixture of alcohol and glycerin. In the presence of moisture, however, it rapidly breaks down to acetic acid and salicylic acid.

3. Phenobarbital soluble (phenobarbital sodium) is not considered stable on keeping in aqueous solution. In case an elixir of phenobarbital is desired, it is suggested that phenobarbital itself be used in a vehicle of alcohol and glycerin.

CEREBRAL HEMORRHAGE AS CAUSE OF INFANT MORTALITY

To the Editor:—What should be recorded as the cause of death of an infant, aged 14 days, born of a primipara, in right occipito-anterior presentation, after a hard twelve hour labor? Pantopon, ⅓ grain (0.02 Gm.), was administered at the first stage, and chloroform anesthesia later. No pituitary was given. After moderate resuscitation of the 9 pound (4,000 Gm.) baby girl, she seemed all right, nursing the breast, taking water, functioning and developing normally. At two weeks suddenly she started a fit of crying and ceased to take anything by mouth. After five hours' crying, she quietly relaxed. There was a tendency to hold the head to the right. The right eyelid was partly open, the left eyelid closed. The pupils remained stationary. There was jerky Cheyne-Stokes breathing. The heart beat was intermittent—now slow and now rapid. One minute periods of cyanosis occurred every hour or so. The temperature by rectum was 99 F. She died in eighteen hours from the onset. The stump, which seemed to have healed, oozed bloody serum during the last six hours. Donald McKay, M.D., Flatonia, Texas.

Answer.—The cause of death was most probably cerebral hemorrhage. That the process was a cerebral disturbance is indicated by the tendency to fixation of the head, the suggestion of right facial paresis, nonreacting pupils, and the respiratory and circulatory disturbances. This picture is most often produced by a cerebral hemorrhage, which in this case may be explained by the difficult labor and is supported at least by the oozing from the stump. The factor of trauma is important. There may have been too little hemorrhage to cause death shortly after birth, but continuous oozing might later bring about sufficient accumulation to cause the sudden collapse indicated. The blood was probably deficient in coagulating elements, which is suggested by the oozing from the stump.

TREATMENT OF PERSISTENT URETHRAL DISCHARGE

To the Editor:—I have a case in which early instrumentation and massage of an acutely inflamed prostate seem to have caused a urethral discharge of four years' standing. I have never found any gonococci, and the cellular elements vary from epithelial cells to straight pus and sometimes a number of lymph cells. I have found no tubercle bacilli. The prostate may be slightly enlarged but not nodular; the vesicles are not palpably affected. My irrigations of the bladder with mild antiseptics seem to have provoked a heavier discharge from the urethra. Can you recommend something? Please omit name. M.D., Wisconsin.

Answer.—A recurrent urethral discharge quite often is due to a chronic prostatitis and vesiculitis. Overflow of the exudation out of these organs then appears periodically as a urethral discharge. Digital stripping of the organs attached to the urethra often is insufficient in bringing about complete emptying of the prostate and seminal vesicles. By massaging the prostate and vesicles, one can secure satisfactory results. Decided improvement and in numerous cases eventual cure will be brought about by systematic massage combined with medical diathermy of these organs. Each treatment should be followed by instillation into the posterior urethra of an aqueous solution of strong silver protein, from 0.25 to 0.5 per cent in strength. Repeated endodermic injections of some foreign protein have also a salubrious effect.

District of Columbia July Examination

Dr. W. C. Fowler, secretary of the Commission on Licensure of the District of Columbia, reports the written examination held at Washington, July 14-15, 1930. The examination covered 6 subjects and included 60 questions. An average of 75 per cent was required to pass. Fourteen candidates were examined and passed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
Yale University School of Medicine	(1924)	87.1
Georgetown University School of Med.	(1929) 82.3, (1930)	84.5
George Washington University Medical School	(1929)	78.6, 82.7, 84, 85.5, (1930) 85.3
Emory University School of Medicine	(1925)	78
Johns Hopkins University School of Medicine	(1927)	87.4
Harvard University Medical School	(1925)	85
University of Virginia Department of Medicine	(1926)	85, 85.4
Queen's University Faculty of Medicine	(1926)	78.7

Wisconsin June Examination

Dr. Robert E. Flynn, secretary of the Board of Medical Examiners of Wisconsin, reports the written and practical examination held at Milwaukee, June 24-27, 1930. The examination covered 19 subjects and included 100 questions. An average of 75 per cent was required to pass. Seventy-six candidates were examined and passed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
Loyola University School of Medicine	(1929) 88, (1930)	85
Northwestern University Medical School	(1930)	85, 86
Rush Medical College	(1930)	75, 79, 85, 85, 85, 85, 86, 87
University of Illinois School of Medicine	(1930)	81, 87
Harvard University Medical School	(1929)	85, 86, 86
Washington University School of Medicine	(1929)	89
Columbia University College of Phys. and Surgs	(1929)	85, 85
University of Oregon Medical School	(1929)	86
University of Pennsylvania School of Med.	(1928) 86, (1929)	87
Marquette University School of Med.	(1930)	78, 80, 80, 80, 81, 81, 82, 82, 82, 82, 83, 83, 83, 84, 84, 84, 85, 85, 85, 86, 86, 86, 86, 86, 86, 86, 87, 87, 88, 89, 89, 89, 90
University of Wisconsin Med. School	(1928) 86, (1929)	81, 82, 83, 84, 84, 85, 85, 86, 86, 87, 87, 88, 88, 88, 88, 90, 90
University of Manitoba Faculty of Medicine	(1916)	84
Leopold Franzens University Faculty of Med., Austria	(1919)	80

Dr. Flynn also reports 22 physicians licensed through reciprocity with other states and 1 by endorsement of National Board credentials, at the meeting held in Milwaukee, June 24-27, 1930. The following colleges were represented:

LICENSED BY RECIPROCITY

College	Year Grad.	Reciprocity with
University of Arkansas School of Medicine	(1929)	Arkansas
Northwestern Univ. Med. School	(1896) (1907) (1929, 2)	Illinois
Rush Medical College	(1927, 2) (1928, 2) (1930, 2)	Illinois
University of Kansas School of Medicine	(1929)	Kansas
University of Minnesota Medical School	(1929) (1930)	Minnesota
Barnes Medical College	(1906)	Illinois
Jefferson Medical College	(1891)	Illnois
Meharry Medical College	(1928)	Tennessee
Vanderbilt University School of Medicine	(1928)	Tennessee
University of Wisconsin Med. School	(1928) Illinois, (1929)	Nebraska
University of Liverpool Medical School	(1925)	Illinois

Nevada May Examination

Dr. Edward E. Hamer, secretary of the Board of Medical Examiners of Nevada, reports the oral and written examination held at Carson City, May 5-7, 1930. The examination covered 10 subjects and included 90 questions. An average of 75 per cent was required to pass. One candidate was examined and passed. The following college was represented:

PASSED

College	Year Grad.	Per Cent
George Washington University Medical School	(1924)	88.3

Book Notices

USEFUL DRUGS: A LIST OF DRUGS SELECTED TO SUPPLY THE DEMAND FOR A LESS EXTENSIVE MATERIA MEDICA WITH A BRIEF DISCUSSION OF THEIR ACTIONS, USES AND DOSAGE. Edited by Robert A. Hatcher, Ph.M., Sc.D., M.D., and Cary Eggleston, M.D. Prepared under the direction and supervision of the Council on Pharmacy and Chemistry of the American Medical Association. Eighth edition. Cloth. Price, 60 cents. Pp. 176. Chicago: American Medical Association, 1930.

The appearance of a new edition of Useful Drugs is timely in view of the issue between the medical and nonmedical delegates on the floor of the Pharmacopeial Convention in May of this year. In a recent editorial discussing the attack on the physicians' right to apply the doctrine of therapeutic usefulness as a criterion for revision of the Pharmacopeia, THE JOURNAL again urged adherence to Useful Drugs as a safe guide to essential therapeutic preparations selected from the Pharmacopeia, the National Formulary and New and Nonofficial Remedies, stating that the need for such adherence by physicians will be even greater in the future than it has been in the past.

Useful Drugs is prepared under the direction and supervision of the Council on Pharmacy and Chemistry of the American Medical Association, the editors of the present volume being Dr. Robert A. Hatcher, a member of the Council, and Dr. Cary Eggleston. It presents a brief and comprehensive discussion of a selected list of drugs and is designed to supply the demand for a less extensive materia medica and therapeutics and for examinations in these subjects by the various licensing boards. The first edition of the book was prepared some fifteen years ago as a result of efforts made by the Council on Medical Education of the American Medical Association and the Confederation of State Examining and Licensing Boards to restrict instruction in materia medica to a fundamental list of drugs with which all medical students and practitioners might be expected to be familiar. Such a list was made and, after various revisions and critical suggestions from many representative members of the medical profession, was published in 1913. Since then the text has gone through several additions and revisions undertaken with a view to the deletion of drugs deemed to have become superfluous and the addition of others the value of which has become established.

Articles newly included in the eighth edition are: amidopyrine, diphtheria toxin for the Schick test, diphtheria toxoid, ephedrine, ephedrine hydrochloride, ephedrine sulphate, liver extract, merbaphen (novasurol) and mersalyl (salyrgan). Articles deleted from the book are: aconite, tincture of aconite, stramonium, and strychnine nitrate. The statements of actions, uses and dosage have been carefully revised to bring them up to date with the latest and best results of therapeutic and pharmacologic research. A copious index is provided.

DIE BEHANDLUNG DER RHEUMATISCHEN KRANKHEITEN. Herausgegeben von Privatdozent Dr. med. Arnold Zimmer. Mit einem Geleitwort von Geh.-Rat Prof. Dr. A. Bier. Paper. Price, 19.50 marks. Pp. 268, with 47 illustrations. Leipzig: Fischers medizinische Buchhandlung, H. Kornfeld, 1930.

The authors of this volume have been associated with the Professor August Bier Klinic in Berlin, and Professor Bier has written the foreword. Apparently the book is based on the experiences of this clinic and the treatment advised is that employed in this clinic. The term "rheumatic disease" is used in a generic sense, covering the various types. The chapter on medical treatment is written by Dr. Bruno Thom. Under the head of general treatment, the use of insulin is advised to increase the appetite of undernourished individuals. Under the head of treatment with specific antirheumatic remedies (and, by the way, the consensus at present is that the salicyl group is not specific in the true sense of the word) a large number of German proprietary preparations are indicated. It is the opinion of the author that in the milder types of acute polyarthritis the salicyl treatment lessens the treatment of cardiac complications. This statement is almost certainly fallacious. As Bier was the father of the passive hyperemic therapy, which he now considers a form of foreign protein therapy, it is not surprising that a chapter is devoted to the use of nonspecific protein or fever therapy. This chapter is written by Zimmer, The author believes that certain proprietary preparations capable of exciting a fever reaction are more valuable than some simple preparation such as typhoid vaccine. Chapter IV, on the surgical treatment of chronic arthritis, was written by Prof. Wilhelm Baetzner. Chapter V, on the orthopedic treatment of rheumatic disease, was written by Dr. H. Beck. Then follows a chapter on physical therapy by Dr. Ludwig von Pap; a chapter on balneotherapy by Hirsch; a chapter on massage and gymnastics by Kahlrausch; endocrine disturbances and rheumatic disease by Fehlow; technic of the reduction cure by Richter; venereal disease and rheumatism by Richter. Zimmer and Kempf have chapters on the relation of varicosities to arthritis deformans and their treatment. They believe that the varicosities observed frequently in the neighborhood of the affected joint, especially the knee, may be a factor in the discomfort or disability in this disease and advise their treatment by injections. Then follows a chapter on the treatment of gout by von Pap. The final chapter, by Zimmer, is on the interferometric method of Abderhalden's reaction as a diagnostic means in chronic rheumatic disease. This volume contains little, if any, information of value that may be regarded as new in the treatment of rheumatic diseases.

Disease and the Man. By George Draper, M.D., Associate Professor of Clinical Medicine, Columbia University. Cloth. Price, $4.50. Pp. 270, with illustrations. New York: Macmillan Company, 1930.

Among the leaders in American medical thought who urge a return to the hippocratic doctrine of viewing the man as a whole is the author of this book. The previous volume on "Human Constitution" appeared some years ago. The present book carries on the studies since that date. Many of the chapters have appeared in medical and biologic periodicals. An introductory chapter is followed by discussions of genetics, morphology, the influence of sex in determining human disease potentiality, the psychologic panel, the constitutional clinic, and the patient and his physician. Each of these chapters emphasizes the main thesis of the work as a whole and several contain illustrative cases indicating the clinical application of the study of constitution. The view that the investigation of disease requires knowledge of heredity, constitution, environment and personality no longer needs argumentative support. The problem of today is to secure application of this conception by general practitioners, specialists, industrial physicians and group practitioners who are crowded for time, insufficiently remunerated and economically incapable of making the type of study that a constitutional clinic demands.

Ricerche anatomo-cliniche su alcune emopatie. Da L. Riccitelli, aiuto e docente. Paper. Pp. 151. Pisa, 1930.

This brochure is made up of four articles concerned with various aspects of hematology. The titles will give an idea of the topics treated. The first article is on the existence of an acute hemocytoblastic aleukemic syndrome as an anatomic and clinical entity. The second treats of splenomegalic pernicious anemia and its relations with the ordinary pernicious anemia and with the splenomegalic hemolytic anemias. The third has to do with the relations between the agranulocytosis of Schultz and other abnormal blood conditions. The last is entitled the problem of the neuro-anemic syndromes.

Intern's Handbook: A Guide to Rational Drug Therapy, Clinical Procedures and Diets. By Members of the Faculty of the College of Medicine, Syracuse University. Under the direction of M. S. Dooley, A.B., M.D., Chairman, Publication Committee. Cloth. Price, $3. Pp. 254. Philadelphia: J. B. Lippincott Company, 1929.

This book has been prepared by members of the faculty of Syracuse University with a view to encouraging the proper use of drugs by interns and with a view to providing the intern with a ready reference to the subjects which he might be called to know in an emergency. The list of drugs is essentially a list of useful drugs somewhat more abbreviated than that which appears in the volume prepared under the auspices of the Council on Pharmacy and Chemistry. Following the list of drugs is a section on the treatment of poisoning and a section on such essentials of clinical pathology as might occupy the attention of the intern in the average general hospital. The rules governing roentgenology are planned to aid the intern with his work in that department. The section on diagnosis consists essentially of outlines of the most used procedures. There are also sections on diets, on serums and vaccines, on obstetrics, and on other specialistic procedures. The book has a good index and there are plenty of blank pages for important notes.

Neue Deutsche Klinik: Handwörterbuch der praktischen Medizin mit besonderer Berücksichtigung der inneren Medizin, der Kinderheilkunde und ihrer Grenzgebiete. Herausgegeben von Prof. Dr. Georg Klemperer und Prof. Dr. Felix Klemperer. Band III: Echinokokkenkrankheit—Gelenkerkrankungen (chronische). Cloth. Price, 40 marks. Pp. 805, with 235 illustrations. Berlin: Urban & Schwarzenberg, 1929.

The third volume of this new encyclopedia of medical practice is essentially a collection of thirty-six monographs covering such subjects as eclampsia, eczema, electrical diagnosis and treatment, inflammation, enuresis, epilepsy, vomiting, the catching of cold, ferments, fevers, obesity, fractures, hospitals, furuncles, gallstones, obstetrics, brain abscess and tumors, psychiatry, and yellow fever. The German names for those conditions make the titles range from echinococcus diseases to *disturbances of the joints (Gelenkerkrankungen)*. Like the previous two volumes, this book is printed entirely on coated stock. It is superbly illustrated. The articles are sufficiently long to cover every important fact of the subjects considered and they are quite up to date. Practically all of them are written by German authors who have achieved importance in the fields concerned. Thus, those dealing with pathology are by Gerlach, director of the pathologic institute at Halle; the article on encephalitis is by von Economo, who is credited with having made the first modern identification of this subject in 1916; the subject of fractures is illustrated with more than a hundred plates, showing the fractures under the x-rays and the various devices used in treatment. One of the most valuable articles in the book is that on the deformities of the feet and ankles by Stracher. Each of the articles is complete with bibliographic notes, many of them referring to literature as recent as 1927 and 1928. By typographic display, important points are fully emphasized. This encyclopedia goes so far beyond any available similar work in English that comparison is impossible.

Care of Aged Persons in the United States. Bulletin of the United States Bureau of Labor Statistics, No. 489. Paper. Price, 70 cents. Pp. 305, with 40 illustrations. Washington, D. C.: Supt of Doc., Government Printing Office, 1929.

This volume provides a complete survey of the care of the aged by federal, state and local governments, by fraternal, labor, religious and private organizations, by employers and by special funds. There are 1,270 homes for the aged in this country and data have been obtained for 1,037. They care for approximately 70,000 people. About 85,000 people are cared for in almshouses. The data are invaluable to any one interested in the subject. They cover diets, furnishings, costs, systems of support, insurance and medical care.

Praxis und Theorie der [illegible] e zur Einführung in die Psychot[illegible] und Lehrer. Von Dr. Alfred Adl[illegible] 12.80 marks. Pp. 245. Munich: J. F. Bergmann, 1930.

Dr. Alfred Adler of Vienna presents in his book on individual psychology a series of lectures or discussions intended to be an introduction to psychotherapy particularly of interest to physicians, psychologists and teachers. He elucidates his well known and interesting conceptions as to the development of the neurotic and the psychotic individual, explains the attitude of the neurotic person toward life and society, gives an understanding of the goal or aim of these individuals and thereby affords a better insight into the prevention and treatment of these modes of individual reaction. Adler explains the strivings for superiority of neurotic individuals, the masculine protest, the extreme egotism and excessive ambition at the basis of the neurotic character, which is associated with a feeling of inferiority and inadequacy and which interferes with the purposeful activity of the individual and his adjustment to his surroundings. On the basis of his conceptions of the struggle for power and superiority, Adler explains various neuroses, perversions, melancholias, paranoias, and delinquencies in childhood and adolescence. The author attempts to elucidate the attitude and mode of development of the social and antisocial traits exhibited by these persons. He believes that they frequently originate in early childhood.

He emphasizes the necessity of encouraging and developing a social feeling (*gemeinschaftsgefühl*). He thinks that if the neurotic and the maladjusted child could be taught how to cooperate with his fellows the behavior difficulties would be adjusted. In order to achieve this goal, cooperation between parents, teachers and the affected children is necessary. Adler does not see as much in the influence of sex development on the mental habits and behavior as his distinguished teacher Freud. Indeed, Adler declares that he is at variance with Freud on this point and he believes that Freud overemphasizes the sex component in the psychic manifestations. The author stresses the need for prophylaxis, which he thinks will be best advanced by education of parents, physician and teachers in an understanding of the principles of modern individual psychology. He considers that the school offers the most promising possibilities for the control of the problem child. By this he implies that the parents have already failed. In order to achieve results it is important that physician, teacher and parent should cooperate and direct the child in the right directions to prevent maladjustments and teach him that to be normal spells willing and cheerful cooperation. Individual psychology attracts by its simplicity and its content of practical common sense. It offers a working hypothesis for the recognition and possibly the correction of some of the commoner behavior disorders. It attempts to explain to a degree the origin of the mental twists and unpleasant peculiarities of children as well as adults in every rank of society. Because of its practical uses and its application to everyday life, individual psychology has exerted a great influence on modern thought in the practice of medicine, pedagogy and psychology. It is not a complete and comprehensive system. It fails to explain to complete satisfaction origins, course and progress of many of these psychic deviations. Adler does not seem to take into account the influence of heredity, though he does speak of constitutional and physical deficiency as the basis of psychic inferiority. Individual psychology represents the thoughts and concepts of Alfred Adler. As such it is probably not all embracing or all enduring. Nevertheless he has founded a school and has succeeded in attracting ardent adherents in every part of the world as well as securing the marked attention of thoughtful persons in pedogogy, educational psychology and medicine.

THE DIETARY OF HEALTH AND DISEASE FOR THE USE OF DIETITIANS, NURSES AND INSTRUCTORS IN THE SCIENCES THAT PERTAIN TO NUTRITION. By Gertrude I. Thomas, Instructor in Dietetics, University of Minnesota. Second edition. Cloth. Price, $2.50 net. Pp. 276, with 5 illustrations. Philadelphia: Lea & Febiger, 1930.

This is offered as a textbook for schools of nursing and of home economics. The book is compiled from a dozen larger books and from the periodical literature. It seems to include just about all that those for whom it is intended should and can assimilate. It is concerned largely with tables of food values, recipes, special diets and similar subjects. It is fairly well organized but the addition of new material in the second edition has disturbed the organization. Thus the ketogenic diet is covered on pages 180-183 and again under epilepsy on page 257, where it is called the Peterman diet and quoted in full from his article in THE JOURNAL but not referred to under ketogenic diet in the index.

ULTRA-VIOLET RADIATIONS AND THEIR USES. By Robert Aitken, M.D., F.R.C.P.E., Lecturer on Diseases of the Skin, Edinburgh University. With a foreword by Sir Norman Walker. Cloth. Price, 10/6 net. Pp. 208, with 15 illustrations. Edinburgh: Oliver & Boyd, 1930.

This book completely covers the subject of ultraviolet radiation. In it the author briefly reviews the physics of light and its biologic effects. The rôle of the layers of the skin in the transmission of light, the changes produced in the blood stream, and the pathologic effects of ultraviolet radiation are clearly and lucidly stated. In the chapter dealing with apparatus the author differentiates between the carbon and the mercury arc, evaluates the energy derived from these sources, and states the indications for its use. A goodly portion of the book is devoted to technic. Here the author discusses the use of dosimeters and the significance of erythema and explodes the theory that ultraviolet radiation is contraindicated in pulmonary tuberculosis and in acute ailments in infants and in the aged. The major portion of the book is devoted to the treatment of various diseases all anatomically classified. The author cites not only his own experiences but those of his co-workers in the field of actinotherapy. An excellent bibliography is included. The book is systematic and thorough and should be useful both to students and to practitioners.

GROWING UP IN NEW GUINEA. A Comparative Study of Primitive Education. By Margaret Mead, Assistant Curator of Ethnology, American Museum of Natural History. Cloth. Price, $3.50. Pp. 372, with illustrations. New York: William Morrow & Company, 1930.

The author, as shown in her book "Coming of Age in Samoa," has the peculiar faculty of telling anthropologic and ethnologic facts in a way to interest the general reader. The group that she discusses in this book has a character different from that of most other groups of human beings; its tabus differ from those of most other peoples. The children are reared by a method that gives them independence early in life, and a responsibility for their acts that might well suggest methods to educational psychologists of more civilized communities. The sex life has a particular form of restraint somewhat like the puritanical concepts of the Victorian Age and of America previous to 1900. The manner in which this sex life inhibits character development is detailed by the author. There are eleven appendixes to the book giving specimens of the method of study and of the development of the Manus people. Miss Mead is convinced that imitation is the most powerful teacher, much more powerful than any adult technic, and she is inclined to deprecate the power of education to overcome biologic traits in human life. It makes no difference what one teaches in the school provided adults at home and away from home established other methods of conduct.

GUIDE TO THE SURGICAL INSTRUMENTS AND OBJECTS IN THE HISTORICAL SERIES WITH THEIR HISTORY AND DEVELOPMENT. By C. J. S Thompson, M.B.E., Hon. Curator of the Historical Section of the Museum With a foreword by the Conservator, Sir Arthur Keith, M.D., F.R.C.S. F.R.S. Boards. Pp. 92, with illustrations. London: Royal College of Surgeons of England, 1929.

The author is best known for two excellent books on the history of poisons and of quacks. As curator of the museum of the Royal College of Surgeons he has studied the history o medical technic. His guide is a history of the developmen of medical accessories and apparatus including the scalpel, the tourniquet, the forceps, the stethoscope, the thermometer and what not. The book also describes faithfully the anatomic preparations in the museum, Lister's instruments, the hands o several famous surgeons, and innumerable other objects o interest. For those who have visited the museum it is a memento of great value; others who read the little guide will impatiently await their first visit.

A TEXTBOOK OF THE PRACTICE OF MEDICINE. By Various Authors. Edited by Frederick W. Price, M.D., F.R.S., Consulting Physician to the Royal Northern Hospital. Third edition. Cloth. Price, $11.50. Pp. 1871, with illustrations. New York: Oxford University Press, 1929.

Since the first edition of this book, which appeared in September, 1922, there have been five reprintings of that edition and two of the second. Obviously it must have had an excellent sale. The third edition has been thoroughly revised. Many new articles have been added covering such subjects as vitamins, glandular disorders, electrocardiographic studies, and several unusual diseases of which much has been written in recent years. Following the announcement of new discoveries, changes in classification have been made. Yellow fever, phlebotomus fever and dengue have been moved from the section on spirochetal infections to that on infectious diseases of unknown etiology. Rickets is now classified as a deficiency disease. There have been complete rewritings and additions to articles on encephalitis, scarlet fever, malaria, syphilis and hyperthyroidism. This volume, to which many authors have contributed, is a good representative of modern clinical practice in the British Isles. Twenty-six leading practitioners are listed as contributors. Beginning with a general article on fever, infection and immunity, it covers immunotherapy, then various infections, tropical diseases, parasitic disorders, chemical and physical disturbances, metabolic disorders, and glandular, digestive and circulatory disturbances. Then come diseases affecting various systems and finally psychologic medicine. Unfortunately, the book is poorly printed, on poor paper with occasional smudging of type. The letters are small and the printing shows through the thin stock. In general the articles are of a high order. They are well written, systematic, easily followed and quite up to date. The therapy is simple, and the volume does not seem to have been written primarily to promote unestablished proprietaries, as has been the case with many other foreign systems. The general practitioner will find this one of the best ready reference books he can have at hand.

Medizinische Anthropologie: Eine wissenschaftstheoretische Grundlegung der Medizin. Von Dr. Oswald Schwarz, Privatdozent an der Universität Wien. Paper. Price, 13 marks. Pp. 383. Leipzig: S. Hirzel, 1929.

It should no doubt have been realized from the first that it is impossible to separate the science of medicine from all other sciences that deal with the structure, the life and the birth of man. Lately, however, it is being realized more and more that anthropology is one of the most fundamental of sciences with which medicine must be concerned. Schwarz has therefore prepared an outline of anthropology directed primarily to the physician rather than to the public. He begins by showing the relationship of medicine to other sciences. After discussing the diseases of man and the responsibility of man for carrying on human culture, he turns to the position of anthropology in the system of knowledge, the fundamental aspects of anthropology in relation to medicine, and the present tendencies of thought in the medicine of today. He recognizes the fact that medicine is turning more and more to the study of personality and of the individual rather than of mankind. He lists Bauer, the pathologist, Krehl and Freud as some of the greatest leaders in this modern movement. Indeed, he is inclined to call Freud the most advanced of all the modern leaders who are concerned with the progress of modern medicine.

Diseases of Women. By Ten Teachers under the direction of Comyns Berkeley, M.A., M.D., M.C., Obstetric and Gynæcological Surgeon to the Middlesex Hospital. Edited by Comyns Berkeley, H. Russell Andrews and J. S. Fairbairn. Fourth edition. Cloth. Price, $6 net. Pp. 558, with 184 illustrations. New York: William Wood & Company, 1930.

This edition shows considerable revision and improvement. Like previous editions, it is a collective effort of ten of the leading gynecologists of England. It is simply and tersely written, is well illustrated, and should be a valuable work for students in gynecology, including as it does a complete section on the principles of technic of gynecologic surgery. The chapters on ectopic pregnancy are well written and the work includes an excellent and important chapter on chronic ill health in women from the psychologic standpoint: neurasthenia in relation to pelvic disorders, a subject that American textbooks might do well to include. The American gynecologist will be surprised by the liberal use recommended for the uterine sound, the recommended methods of examination of discharges, the fact that general anesthesia is recommended for the Rubin patency test, and the absence of any mention of the cautery treatment of endocervicitis. Devoting a chapter each to acute and chronic endometritis is distinctly at variance with American teaching. However, the pleasing and informal style in which the entire book is written, together with the fact that it presents an accurate picture of British gynecology of today, should make this volume a desirable addition to the gynecologist's library.

Die Arten der Schlaganfälle des Gehirns und ihre Entstehung. Von Dr. Ph. Schwartz, a. o. Professor an der Universitat, Frankfurt a. M. Paper. Price, 48 marks. Pp. 269, with 150 illustrations. Berlin: Julius Springer, 1930.

A consideration of apoplexies in general based on the study of a large series of cases has long been needed to confirm or disprove many of the current theories of the mechanisms of the various types of cerebral vascular accidents. Schwartz has studied hundreds of cases and in his book illustrates his results graphically by means of many beautiful photographs. He considers the macroscopic and microscopic observations in hemorrhage associated with hypertension, in softening associated with arteriosclerosis, and in embolism. He has a complete discussion of the pathogenesis of these various types, comparing and contrasting them in great detail. His conclusions are based on a thorough study and should be read in original detail by all interested in cerebral vascular diseases.

Medicolegal

Mental Capacity Determinable by Physical Condition

(Love v. Love (Md.), 148 Atl. 814)

Margaret Love died, Nov. 2, 1928, aged nearly 96. Certain of her grandchildren who had received no recognition under the will contested it. Verdict and judgment were given in their favor on the issues of testamentary capacity and undue influence. The executor then appealed to the Court of Appeals of Maryland.

Dr. Taylor, who attended the testatrix, testified that she was incompetent to make a valid deed or contract on the day she executed the will. Under the well settled rule in Maryland, said the Court of Appeals, he was competent to express an opinion as to the mental capacity of his patient without giving any reasons for his opinion. On behalf of the executor, however, it was contended that Dr. Taylor disqualified himself, after expressing his opinion, by stating that that opinion was based on the physical condition of the testatrix; that he was unable to say whether she had sufficient mental capacity to make a gift; that there was nothing unusual or abnormal about her mental condition, except that she was a failing old lady; that he observed nothing to produce her condition of senile decay, except that she was feeble and failing in health; and that he was unable to say when, in a person suffering from arteriosclerosis, as he testified the testatrix was, the disease would interfere with the blood supply of the brain and lessen its functioning.

The question, said the Court of Appeals, is whether the discussion, on cross-examination, of the ground of the witness' opinion showed that opinion to be so lacking in foundation that it must be stricken from the record, on the motion of the executor, notwithstanding that it was properly admitted. The court held that it was not necessary to strike the opinion from the record. The opinion of the witness, said the court, was undoubtedly weakened, but we cannot say that it was nullified. The weight of it was for the jury to determine. So far as we know, said the court, it has never been held that physical deterioration may not reach a point where the brain ceases to function, although there may not be any specific mental disease. The rulings of the court below were therefore affirmed, and the case remanded.

Parke J., however, dissented. The only witness, he said, who expressed an opinion that the testatrix was incompetent when she made the will was the family physician, whose opinion was shown by his testimony in chief and by his cross-examination not to have been based on any evidence of mental incapacity, and consequently to be without probative force.

Estoppel of Patient to Deny Liability for Services

(Dempsey v. Angelette (La.), 125 So. 887)

The wife of the defendant, Angelette, became ill, and he employed the plaintiff, Dr. Dempsey, to treat her. Dr. Dempsey had treated Angelette and his family for a number of years. The patient did not respond to treatment, and in the early part of January, 1927, Angelette requested Dr. Dempsey to obtain the services of another physician. As the patient was suffering from nausea and vomiting, a stomach specialist was called in. According to the testimony of Angelette and his wife, when they suggested a consultant be summoned, they considered that Dr. Dempsey had given up the case. Nevertheless, after a consultation between Dr. Dempsey and the consultant, the patient was removed to the Touro Infirmary. She remained at the infirmary from January 1 until discharged, January 18, the stomach specialist having decided that the patient was suffering, not from stomach trouble, but from a goiter.

Dr. Dempsey, according to his testimony, continued to render services to the patient while she was in the hospital and thereafter, and later, on Angelette's request, he called in another consultant. This consultant recommended a surgeon who specialized in operations for goiter. The patient was again admitted to the Touro Infirmary, March 18, and after an operation by the surgeon selected was discharged, April 8.

Dr. Dempsey thereafter sued Angelette for $205, claimed as compensation for professional services rendered between Jan 2, 1927, the day after the patient was first taken to the Touro Infirmary, and April 9, 1927, the day following her discharge from the infirmary after she had been operated on. Angelette admitted an indebtedness of $60 but denied liability for the remaining $145. Judgment was rendered in favor of Dr. Dempsey, and Angelette appealed to the Court of Appeal of Louisiana, Orleans.

Angelette and his wife both denied that Dr. Dempsey had treated Mrs. Angelette during the period when she was in the Touro Infirmary. Angelette contended that Dr. Dempsey did not call regularly at the hospital to visit Mrs. Angelette and that when he did call, he, Angelette, was under the impression that it was merely a friendly visit. During both periods when the patient was in the infirmary, the specialist directed and administered all of the treatment that the patient received. Angelette contended, therefore, that he was not responsible to Dr. Dempsey for any visits he made; he considered that Dr. Dempsey turned the case over to the specialist on both occasions. Both the defendant and his wife admitted that they did not discharge Dr. Dempsey. Two physicians testified on behalf of Dr. Dempsey. One testified that it was the custom for the family physician to continue his services unless discharged. The other one testified that it was the custom for the family physician to continue his services if the family requested him to do so.

It appears, said the Court of Appeal, that the defendant did continue his services. While he may not have been solely in charge of the case, he cooperated with the specialists in treating the patient. Angelette, the defendant, at no time objected to Dr. Dempsey rendering such service. If he considered that Dr. Dempsey was no longer in the case, Angelette should have so informed him. It was too late to complain, said the court, after Angelette had received the benefit of Dr. Dempsey's services. The judgment of the trial court for the full amount, in favor of Dr. Dempsey, was affirmed.

Evidence: Dying Declarations.—Before a dying declaration can be admitted in evidence, the trial judge must be satisfied beyond a reasonable doubt that it was made under the realization and solemn sense of impending death. The declaration must be the utterance of a sane mind. It must be restricted to the homicide and the circumstances immediately attending it and forming a part of the res gestae. A declaration, or part of it, is not admissible unless it would be competent and relevant if it were the testimony of a living witness. Great caution should be observed in the admission of dying declarations, and the rules which restrict their admission should be carefully guarded. In this case it was shown that the declarant was of sound mind, that she realized what she was saying, that she had been dangerously wounded internally and that an operation had been performed, and that she did not evince the slightest hope of recovery. When she was making a statement concerning the circumstances under which she was wounded, she said: "I am going to die; I cannot get well; you need not worry about me." About twenty-four hours later, she died. Her dying declaration was held to have been properly admitted as evidence.—*Walton v. State (Miss.), 126 So. 29.*

Practice of Dentistry: Revocation of Licenses.—The Florida statute regulating the practice of dentistry (Acts of 1925, chapter 10109, sec. 18; C. G. L., 1927, sec. 3551) is penal in its nature. It must therefore be strictly construed and strictly followed. The statute authorizes the state board of dental examiners to revoke the license of any dentist shown to have been employing unlicensed persons to perform work which can lawfully be done only by persons licensed to practice dentistry in Florida. There is no provision in the statute for review by appeal or writ of error of the action of the state board of dental examiners revoking licenses, but in such cases, said the Supreme Court of Florida, Division B, it is well settled that mandamus will lie to consider the whole proceeding, wherein it may be determined by the court whether the action of the board will be sustained or the dentist restored to his right to practice dentistry. On a motion for a peremptory writ of mandamus, the court held that an accusation charging a licensed dentist with having violated the dental law of the state, by employing an unlicensed person and allowing that person to practice dentistry in his office, failed to charge the dentist with having committed any act which under the provisions of the statute constituted grounds for the revocation of his license to practice dentistry. The most the evidence showed was that a person not licensed to practice dentistry had on two occasions performed, in the office of the dentist whose license had been revoked, some service which could lawfully be done only by a person licensed to practice dentistry, but there was no evidence that the dentist in whose office he had performed such service had employed him or that he had directed the unlicensed person to perform the work. The board was without authority to consider and act on charges other than those contained in the accusation served. A peremptory writ of mandamus was issued.—*State ex rel. Jordan v. Pattishall et al., State Board of Dental Examiners (Fla.), 126 So. 147.*

Workmen's Compensation Acts: Compensability for Death by Lightning.—It is the settled law in Minnesota that the death of an employee caused by lightning is compensable only when by reason of employment he is so exposed to injury by lightning as necessarily to accentuate the natural hazard and when the accident is incident to his employment. *The employment must expose the employee to the hazard in* some way peculiar to it, so that he does not stand in relation to the hazard in only the same way as the public generally. The Industrial Commission, and later the Supreme Court of Minnesota, was asked to take judicial notice of statements by an expert on the phenomena of electricity and lightning, concerning the relative chances of objects at different heights being struck, and it was insisted that the chance of the deceased workman being struck was enhanced by the fact that he was with large horses on the highway, with no other large objects above the ground.

We may take judicial notice, said the Supreme Court of Minnesota, of that which may be regarded as common knowledge of every person of ordinary intelligence; that is, of that which is or ought to be generally known. We do not take judicial notice of things which are not of common and general understanding. We may take judicial notice of scientific facts which universal experience has rendered axiomatic; that is, generally recognized scientific facts. The doctrine should be extended, where it may reasonably be accepted, rather than restricted; yet we cannot take judicial notice of such facts as are known, if at all, only by a specially informed class of persons. We may take notice of the use of lightning rods and that they are to some extent effectual within their immediate area, but to go to the extent now asked would take us into the field known only, if at all, to the scientist and the technician. The rule does not permit that. The Industrial Commission properly rejected the application of the doctrine of judicial notice in this case.—*Lickfett v. Jorgenson et al. (Minn.), 229 N. W. 138.*

COMING MEETINGS

American Academy of Physical Therapy, Boston, November 12-14. Dr. Thomas L. Smyth, 111 North Eighth Street, Allentown, Pa., Secretary.
American Association of Railway Surgeons, Chicago, November 5-7. Dr. Louis J. Mitchell, 29 East Madison Street, Chicago, Secretary.
Central States Pediatric Society, Memphis, Tenn., November 7-8. Dr. A. H. Parmelee, 310 South Michigan Boulevard, Chicago, Secretary.
Medical and Surgical Association of the Southwest, El Paso, Texas, November 6-8. Dr. W. Warner Watkins, Box 1587, Phoenix, Ariz., Secretary.
Radiological Society of North America, Los Angeles, December 1-5. Dr. I. S. Trostler, 25 East Washington Street, Chicago, Secretary.
Southern Medical Association, Louisville, Ky., November 11-14. Mr. C. P. Loranz, Empire Building, Birmingham, Ala., Secretary.
Southern Surgical Association, Lexington, Ky., December 9-12. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.
Western Surgical Association, Kansas City, Mo., December 5-6. Dr. Frank R. Teachenor, 306 E. Twelfth St., Kansas City, Mo., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

William Heberden the Elder, 1710-1801. J. Ruhrah, Baltimore.—p. 619.

Relation of Protein Intake to Nitrogen Retention and Albuminuria in Nephrosis.—A case of chronic glomerular nephritis in a child whose condition, under observation, passed into the so-called nephrotic subgroup of glomerular nephritis is presented by Cowie et al. These studies demonstrate that, in this case of nephrosis in a child characterized by a high metabolic rate, a protein intake sufficient to induce a positive nitrogen balance of from 1 to 3.76 Gm. was necessary and sufficient to keep the patient edema-free. This amount of protein caused a marked diminution of the urinary albumin but it did not cause the albumin to disappear after a continuous edema-free period of eleven months. A blood protein content of 5 Gm. was necessary before the patient became permanently edema-free. At one time the patient was edema-free when the serum protein was 3.8 per cent. In. studies of nitrogen balance the actual chemical estimation of the nitrogen in the stool is shown to be necessary.

Heliotherapy and Peripheral Blood.—Hoeffel and Lyons are of the opinion that there is no justification for the belief that light rays, considered either collectively as including the entire spectrum or individually as ultraviolet rays, have any specific effect on the blood. The effect of light on the healing of a pathologic process, such as tuberculosis, cannot be distinguished from that exerted by other factors the beneficial influences of which are well recognized.

Diagnostic Value of Sodium Fluorescein in Epidemic Meningitis.—A study of the value of sodium fluorescein as a diagnostic agent in epidemic cerebrospinal meningitis is presented by Bonar and Bailey with observations in thirty-three examinations in twenty-one cases. Ingested or injected sodium fluorescein permeated the meningeal barrier in all but two uncured patients with clinically and bacteriologically diagnosed epidemic cerebrospinal meningitis. A probable explanation for the failure of the test in these two patients is proffered. The test is of value in the differentiation of epidemic cerebrospinal meningitis from other diseases in which sometimes there are manifestations of meningeal irritation, such as pneumonia, erysipelas, spasmophilia, encephalitis, tumor of the brain and tetanus. The presence of small amounts of blood does not invalidate the test, which makes it especially valuable in the diagnosis of meningitis.

Acute Suppurative Thyroiditis in Children.—Two cases of acute suppurative thyroiditis in children, aged 2½ and 13 years, with operative recovery, are recorded by Mora. In both cases the primary infection was a sore throat, and in both instances the offending organism was a hemolytic streptococcus.

Differential White Count in Infancy.—The differential blood count of thirty-seven normal and sick infants was studied by Smith from a supravital preparation and from fixed smears, and the observations were correlated. In forty-three of forty-eight comparative smears, the percentage of polymorphonuclear leukocytes was higher, and that of lymphocytes was lower in the living preparation than in the fixed film. The average of twenty-four counts from the group of normal infants showed the proportion of polymorphonuclear neutrophils to be 8.6 per cent higher in the supravital than in the fixed cover-slip smear and almost 12 per cent higher than in the slide. The lymphocytes, on the other hand, ran 14 per cent and 11 per cent higher in the fixed smear of the slide and cover-slip, respectively, than the corresponding cells of the supravital preparation. The principal reasons for this discrepancy are unequal distribution of the cells and, especially, failure to identify and include all fragmented polymorphonuclear leukocytes in the differential count of the fixed smear. With the supravital technic, the spread of cells is more even, trauma is reduced, and both motile and dying cells may be more readily identified. In pyogenic infections, especially when associated with a leukocytosis, the differential count from the fixed smears gives at times a much lower polymorphonuclear and a higher lymphocyte percentage than expected. That this discrepancy is often due to an increased fragility of the polymorphonuclear leukocytes is evident from comparative supravital studies. In a routine differential count from the fixed smear, particularly when it is employed as an index of the patient's resistance, the extent of white cell damage encountered on the slide should be noted. If fragmented cells have been included in determining the individual cell percentages, mention of this fact should also be made.

Sepsis with Leukopenia in Children.—Ten cases of the clinical syndrome of a sepsis, with severe anemia, thrombopenia and agranulocytic leukopenia are reported by Bigler and Brennemann. Their relationship to aleukemic leukemia, aplastic anemia, agranulocytic angina and other conditions is discussed.

Problem of Dental Caries.—Evidence is given by Bunting et al. in support of the view that dental caries is a specific infective process the activity of which is dependent on certain metabolic states. As the result of dietary and therapeutic experiments, active dental caries was reduced to a negligible quantity in 433 children. Of the methods employed, dietary measures appeared to be the most important. The diets prescribed for the control of dental caries were well balanced, well fortified, adequate rations in which sugar was reduced to the minimum.

Diffusible Blood Serum Calcium in New-Born Infants.—Studies of calcium partition in the blood serum of fifty new-born infants, ranging from 5 to 22 days in age, are reported by Ray and Phatak, together with determinations of the serum inorganic phosphates, chlorides and protein fractions and the whole blood cholesterol. The total serum calcium, as determined in thirty-two cases, averaged 11.4 mg. per hundred cubic centimeters of serum. The average diffusible serum calcium, as estimated in forty-two determinations, was 5.3 mg., or 46.7 per cent. The nondiffusible calcium averaged 6.2 mg., or 53.6 per cent, in thirty-one determinations. No significant statistical correlation could be found between the total or diffusible calcium and the inorganic phosphates, protein fractions, chlorides or cholesterol. A chart is presented showing the frequency distribution of the total calcium, the diffusible calcium in the serum and the diffusible calcium in the filtrate. It is suggested that studies of calcium partition are of definite use in the interpretation of any clinical condition involving calcium disturbance.

Pneumonia in Children.—The cases of 147 patients with pneumonia admitted to the children's medical division of Bellevue Hospital from Nov. 1, 1928, to April 30, 1929, were studied clinically and bacteriologically by Plummer et al. A control series of 161 children was studied at the same time and by the same bacteriologic methods. The accuracy of the throat swab method of typing is shown by a series of thirty-seven cases in which cultures were obtained from the sputum, blood, ear exudate, chest fluid or specimens procured by postmortem puncture of the lung or at autopsy. The unclassified group in the 147 cases of pneumonia was reduced from 81.6 to 49.7 per cent by the separation of the ten new types of Cooper, Edwards and Rosenstein. The incidence of types in the 147 cases of pneumonia in children is tabulated. The incidence of types in the 161 control children, seventy-two of whom had respiratory infections but not pneumonia, is tabulated; 73 per cent had pneumococci in the throat; 29 per cent had one of the fixed types, and 44 per cent had unclassified strains. The incidence of types according to age is recorded. The incidence of pneumonia in general is high in the first year and drops rapidly after that. A higher incidence of the fixed types was found after the first year. The cases are classified according to clinical diagnosis. There was a predominance of types I, II, IV, VII and IX in the cases of lobar pneumonia and a high incidence of type VI in the cases of bronchopneumonia. The mortality rate in the 147 cases of the series is 17.7 per cent, and the variation according to type is reported.

Nitrite Reaction as Diagnostic Test in Influenzal Meningitis.—A positive nitrite reaction with the spinal fluid was obtained by Greenthal in thirteen consecutive cases of influenzal meningitis, and was always absent in meningococcic, tuberculous and streptococcic meningitis. The nitrite test, according to the method described, may be used as a rapid corroborative test for the diagnosis of influenzal meningitis.

Infectious Mononucleosis.—A case of infectious mononucleosis in a baby, aged 7 months, is reported by Price with a general discussion of the disease. Especial reference is made to the difficulty in diagnosis between infectious mononucleosis and acute lymphatic leukemia in the early stage.

Digestion: Efficiency with Various Foods and Under Various Conditions.—The amount of residue obtained after the digestion of various foods has been studied by Childrey et al. in six dogs, all deprived of the colon. The foods best digested were meat, rice, dextrose and fat in small amounts. These foods might well be used in the treatment of patients with diarrhea and in the preoperative or postoperative care of patients with serious diseases of the colon, rectum or anus. The combining of certain foods such as bread and milk and raw egg and milk, improved the digestion of both substances. Lactose, when given in considerable amounts, proved to be a laxative that interfered not only with the digestion of food eaten the same day but also with the digestion of food eaten the following day. Cheese and lard given one day also interfered with the digestion of food eaten the following day. Meat was better digested when given in lumps than when given finely comminuted. The same was true of Swiss cheese. Raw meat was better digested than cooked meat. Except in the case of a few foods, it was difficult to give enough so that the efficiency of digestion would fail. The dog usually protected himself by vomiting part of the meal. Raw egg when not mixed with other foods was highly indigestible. Raw cornstarch given alone was almost completely indigestible. The addition of lemon juice to food hurried the progress of residue through the bowel and interfered somewhat with the efficiency of digestion. Orange juice had little effect on digestion. Pie crust did not seem to be much more indigestible than white bread. It was more digestible than graham bread. Anxiety and excitement influenced adversely the efficiency of digestion. Food when taken in one large amount was better utilized than when taken in several fractions at half-hourly intervals. Apparently each feeding stimulated peristalsis and caused the food to pass too rapidly through the bowel. Purgatives, sodium bicarbonate and barium sulphate interfered with digestion. Morphine slowed the progress of material through the bowel. It had little effect on the digestion of ground cooked meat, given at the same time, but it interfered with the digestion of meat given the next day.

Addison's Disease in a Negro.—The fifth case of Addison's disease in a Negro, with necropsy observations, is recorded by Sala and Jacobi. The other recorded cases are reviewed. A comparison is made with the disease in white persons. The difficulty of diagnosis and the prominence of symptoms not usually stressed in white people are emphasized. The laryngeal and respiratory symptoms are stressed particularly.

Local Immunity of Peritoneum and the Shwartzman Phenomenon.—A modification of the phenomenon of local skin reactivity introduced by Shwartzman is described by Frisch. This modification consists in the employment of an intraperitoneal instead of an intravenous injection of toxic substance twenty hours after such a preliminary inoculation into the skin. By means of this modification, the principle of local peritoneal immunity was demonstrated. Rabbits in which the intraperitoneal injection of *Bacillus typhosus* culture filtrate was able to elicit the Shwartzman phenomenon in previously prepared skin sites were rendered negative to this phenomenon by repeated injections of this culture filtrate intraperitoneally. It was then shown that this skin reaction could still be produced if the reacting factors were introduced intravenously. It must thus be concluded that the immunity produced under these circumstances was of a distinctly local character involving only the peritoneum, and that the entire organism was not yet immune. It was also determined that between three and four injections of *B. typhosus* culture filtrate were necessary to render the peritoneum immune to this filtrate.

Blood Regeneration During Remission in Pernicious Anemia.—From evidence collected from a group of sixty-eight patients with pernicious anemia undergoing remission as a result of liver treatment and from a consideration of the theoretical factors that influence blood regeneration under these circumstances, Riddle concludes that the magnitude of the reticulocyte response is governed directly by the extent of the bone marrow hyperplasia during relapse, and that the rate of the reticulocyte response is governed directly by the dosage of the active principle contained in liver. As the magnitude and the rate of the reticulocyte response are to a certain extent interdependent, the condition of the bone marrow apparently influences indirectly the rate of the response, and the dosage of liver used influences indirectly the magnitude of the response. For four patients whose collected data were satisfactory for mathematical analysis, the blood regeneration was formulated according to an equation used by Robertson to express a general law of biologic growth and regeneration. When the rate at which the reticulocytes in the blood of these patients were transformed into mature erythrocytes was estimated by this equation, the curve representing the concentration of reticulocytes during the reticulocyte response could be duplicated mathematically. It was estimated that in these patients two days was required for the differentiation of reticulocytes in the blood into mature erythrocytes. In two other patients in whom the stimulus to regeneration of blood was less intense, it was estimated that between three and four days was required for the maturation of reticulocytes in the blood to their mature form. A correlation of the relative maturity of the reticulocyte with the amount of reticular material it contained showed that, under the circumstances present, reticulocytes containing small amounts of reticular material disappeared during the following day. When the amount of reticular substance in a reticulocyte was used as a standard for estimating its degree of maturity, it was found that during the early part of the reticulocyte response reticulocytes were liberated in an earlier stage of development than toward the end of the response. The rate at which reticulocytes are liberated from the bone marrow into the blood appears to be a factor of importance which influences the rate and magnitude and velocity of the reticulocyte response. The rate of the liberation of the reticulocytes into the blood seems to be proportional to the rate at which they are formed from the more primitive red blood cells within the bone marrow and to the numbers of reticulocytes being formed there. An increase of a million red blood cells per cubic millimeter of blood is accompanied by an excretion of approximately 10 Gm. of endogenous uric acid in patients with pernicious anemia during early remission.

Size of Red Blood Cells in Anemia: Value in Diagnosis.—The determination of the individual cell volume as suggested by Haden and as recorded by Murphy and Fitzhugh is a more simple means of determining the average cell size than is the measurement of the mean cell diameter. Determinations of the individual cell volume are helpful in differentiating pernicious anemia from other anemias in most instances in which difficulty in diagnosis might arise, the main exception being in the rare condition called aleukemic leukemia. During and shortly following acute loss of blood there is an increase in the average individual cell volume, whereas in anemia resulting from chronic loss of blood the individual cell volume is generally low. Figures presented suggest that with adequate liver therapy the red blood cells of patients with pernicious anemia return to normal volume. An individual cell volume figure greater than normal should indicate inadequate treatment. Not only is the method for determining the individual cell volume a simple one to use, but the information so obtained is also as reliable as is that obtained by measurement of the mean diameter of the red blood cells by the method used.

Iron Metabolism in Pernicious and Secondary Anemia.—There is present in blood serum a partly diffusible iron compound the estimation of which, Riecker says, may be used to determine the presence and degree of iron starvation in disease and likewise the effect of iron medication. The amount of serum iron is increased in hemolytic diseases of the blood and decreased in the presence of long continued hemorrhage or a dietary deficiency of iron. In pernicious anemia, the level of the serum iron usually is higher than normal but becomes normal during remissions in the disease. A remission in pernicious anemia is accompanied by an increase in excretion over the intake of iron, as determined by analyses of stool and urine. In secondary anemia, one rarely finds as marked iron starvation as in experimental hemorrhage in animals on a diet low in iron, and from this standpoint alone the indications for medicinal iron are limited.

Electrocardiogram with Large Q in Lead 3.—Attention is directed by Pardee to the occurrence of records showing left axis deviation of Q-R-S or a normal electrical axis, combined with a large Q wave in lead 3, one that is 25 per cent or more of the largest deflection of Q-R-S in whichever lead this may occur. The majority of such records are obtained from patients with the anginal syndrome, but certain patients with myocardial fibrosis and congestive failure, certain patients with rheumatic heart disease, especially with pericarditis, and a few with hypertension will give such records. Certain patients who have cardiac symptoms but no definite evidence of cardiac disease have been found to show this large Q_3, and rarely (twice in 277 cases) such records are obtained from apparently normal hearts. These records show a clockwise rotation of the vectors of the Q-R-S group, and frequently there is an inversion of T_3 or of T_2 and T_3. Both of these features depend on right ventricular activity, and it is suggested that the finding of a large Q_3 indicates disease of the left ventricle, so that the right ventricle predominates during the spreading of the contraction in spite of the left axis deviation or normal axis direction of Q-R-S. The effect of diaphragmatic movements on the large Q_3 is noted, and it is suggested that the occasional finding of a large Q_3 in normal hearts may be due to an unusual distribution of the branches of the auriculoventricular bundle and that a high position of the diaphragm may be a contributory factor.

Modification of Dextrose Tolerance Test as Index of Metabolic Activity of Liver.—Evidence is presented by Althausen et al. to show the value of the modified dextrose tolerance test as a metabolic liver function test. The test possesses the following advantages: (*a*) It is simple and requires no especial equipment. (*b*) It is harmless to the patient. (*c*) Unlike the levulose and galactose tolerance tests, it is reliable not only in disease groups but also in individual cases. (*d*) It brings out latent functional impairment of the liver and permits one to follow the progress of the disease. (*e*) It checks well with the results of the rose bengal test. (*f*) As a metabolic test, its results are probably independent of biliary obstruction. (*g*) In combination with a dye excretion test, it offers valuable diagnostic aid in toxic cirrhosis of the liver. The chief limitation of the modified dextrose tolerance test is its inaccuracy in cases of diabetes mellitus with marked morning hyperglycemia.

Renal Damage Following Administration of Merbaphen.—Among 741 necropsies, Sprunt found nine instances in which the patients received merbaphen during the clinical course of their illness. In three of these cases, extensive necrosis of the renal epithelium was observed. Attention is drawn to the fact that in one case merbaphen was given under circumstances adverse to its use, while in two cases conditions which may be considered as counterindications were also present.

Transfusion from Group II (A) Donor to Group III (B) Recipient Without Fatal Results.—Burnham reports a case in which a full transfusion, 400 cc., into a recipient weighing but 85 pounds (38.6 Kg.) of group II (A) blood into a group III (B) recipient was accidentally performed, with only slight symptoms: coughing, oppression in the chest, slight dizziness and pain in the lumbar regions. The incompatible transfused blood remained in the circulation of the recipient from three to five days. The absence of serious consequences was shown to be due to the fact that all of the group-specific isoagglutinin a in the recipient's serum was entirely incapable of clumping the group II (A) cells of the donor at body temperature, although it clumped these cells vigorously at room temperature.

Parathyroid Tumor and Changes of Bones.—The following points were noted by Snapper in a patient suffering from extensive decalcification of the bones, combined with violent pain: 1. The illness began as osteitis fibrosa generalisata. Therefore there existed a pseudo-osteomalacic end-stage of Recklinghausen's disease. 2. There was a great increase in the calcium content of the serum. The deviation was considered to be a symptom of hyperfunction of the parathyroids. 3. There was a *small swelling in the thyroid. On account of these facts,* a tumor of a parathyroid gland was suspected, and it was found during operation. After extirpation of this small tumor, clinical recovery occurred.

Experimental Gastric Ulcer: Effect of Consistency of Diet on Healing.—A simple ulcer of the rabbit's stomach (from 1.5 to 2 cm. in diameter) produced by excision, Fauley and Ivy state, heals within thirty days, irrespective of the consistency of the diet. A similar ulcer, but with a silk suture in its base, will heal if the rabbit is fed a soft diet but will tend to become chronic if the rabbit is fed a rough diet. They have confirmed Ferguson's observation that, if an acute lesion is made by this method and the rabbits are kept on a rough diet, a chronic ulcer results in numerous instances. The consistency of the diet has an influence on the healing of an ulcer of the stomach, if other factors that tend to delay the healing are operating simultaneously. These results indicate that in chronic ulcer in man a soft diet would facilitate the healing of the ulcer, which confirms clinical experience and supports the use of a diet of the character of that employed in the generally accepted therapeutic procedures for gastric ulcer.

Basal Cell Carcinoma.—Owen's observations of 836 cases do not indicate that true basal cell carcinoma may occur on the mucous membrane. The review lends weight to the contention that carcinomas having their origin on the mucous membrane lack that low grade of malignancy which the basal cell carcinomas that are situated on the skin possess. It would seem rather hazardous to diagnose as basal cell carcinoma a tumor having its origin from the basal cell layer of the mucous membrane when there are present metastasis and rapid extensive growth consisting chiefly of undifferentiated cells or cells showing squamous characteristics. This tumor seems to be a squamous cell carcinoma.

Neuromuscular Changes in Amyelia and Relation to Those of Congenital Clubfoot.—A study made by Dittrich of the muscles of the lower extremities in a case of amyelia indicates that the muscular alterations are similar to those found in congenital clubfoot, with the exception that the changes are not so far advanced. The appearance of the sciatic nerves in amyelia is similar to that of the nerves in congenital clubfoot, with the addition, in the former, of a marked degree of hyperemia. The relationship of the spinal canal in amyelia to the spinal cord indicates that the primary defect of development is that of the bony portions of the spine.

Changes of Spleen in Subacute Bacterial Endocarditis.—The principal features of the spleen in subacute bacterial endocarditis of the *viridans* type found by Fox were as follows: The most important gross lesion is the infarct. Practically every case shows perisplenitis whether an infarct exists or not. In early stages the organ is not greatly enlarged but suggests a soft splenic tumor of the congestive type. In the later stages the organ is definitely enlarged as the result of hyperplasia of its constituent tissue and the inflammatory and hyperplastic changes incident to infarctions. Hyperplasia of lymphatic elements proper is not a feature of this disease; on the contrary, those tissues are inactive. Hyperplasia of cells of the reticulo-endothelial series is not seen early but appears more evident in the cases of longer duration. Marked changes of the linings of blood vessels are not especially peculiar to this disease. Evidences of destruction of blood are missing in early but are present in older cases. Degenerations and coagulation within germ centers are frequently observed. Structures suggesting Bracht-Wächter bodies have been seen several times. Clasmatocytes are occasionally seen, but rarely in any numbers. Polymorphonuclear neutrophils are prominent, as revealed in spleens of this series of cases of bacterial endocarditis. Eosinophils are also frequently seen.

Correlation of Qualifying Examinations.—Bierring suggests the acceptance of the National Board examination by the medical schools. This would apply only to the written tests in the fundamental medical and clinical sciences.

Experimental Method in Modern Medicine.—Babkin believes that the best way to introduce the experimental method into practical medicine would probably be to train young medical graduates, especially those whose aim is an academic career in medicine or surgery, for a couple of years in the biologic laboratories. By this is meant not so much technical training in some of the biologic sciences—physiology, biochemistry, pharmacology—as the acquisition of a certain mental attitude toward theoretical and practical medical problems. A "scientific" point of view on phenomena under observation, and "scientific" treatment of such, cannot be acquired from books. Only actual research work in a laboratory, and continuous and strenuous mental effort directed toward the solution of certain experimental problems, will teach a young man how to deal scientifically with them. At the present time an attempt is being made in that direction at McGill University by the creation of a scheme of "Experimental Surgery" (supported by the Rockefeller Foundation). Young surgeons, who have proved themselves capable in that branch of medical science, enter one of the biologic laboratories (physiology, biochemistry or pharmacology) and work there for two years as research students conducting experiments, many of which involve operative procedures on animals. They will return afterward to the university surgical clinic, where it is hoped that they will retain and foster within themselves the experimental spirit which they acquired in the laboratories.

Extract of Suprarenal Cortex Substance.—Coffey and Humber discuss in detail their work with suprarenal cortex extract. Under the auspices of the Better Health Foundation of California they intend to carry on a constructive five-year program of scientific research. The Better Health Foundation of California is a nonprofit corporation and was organized to carry on work for the extension of scientific research and other worthy purposes. To obtain the best results it has been decided that the future distribution of their extract for research work to cooperating physicians, clinics or hospitals will be made available through the Better Health Foundation, because in that way improper claims or commercial exploitation of the extract may be better prevented.

Carotinemia.—Miller reports three cases. The first patient with a severe generalized, allergic dermatitis developed a yellow discoloration of the skin of the entire body while eating raw carrots and other vegetables. The second patient, with an ill defined gastric complaint, was diagnosed as having gallbladder disease because the yellow color of her skin was thought to be due to bile pigments. The third patient sought medical care because of the embarrassment of the dirty, yellow color of her palms.

Detection of Insular Hormone in Duodenum.—It would appear from experiments made by Laughton and Macallum that a substance exists in normal duodenal mucosa which has a specific stimulating influence on the islets of Langerhans; in other words, an insular hormone. This, coupled with Workman's observations, introduces a new factor into the etiology of diabetes mellitus. Insular failure may result from excessive stimulation of the islets by the duodenal hormone produced as a result of excessive sugar intake over long periods. Secondly, inflammatory conditions in the duodenum may lead to a deficiency in the hormone, followed by a diminished activity in the islets themselves resulting in a hyperglycemia.

Sclerosis and Occlusion of Coronary Arteries.—Forty-four cases of coronary disease seen in the necropsy service during the past four years have been reviewed by Klotz and Lloyd. Coronary disease of the heart usually affects men between the ages of 55 and 60, rarely before 30, and is the outcome of an endarteritis associated with atheroma and calcification. The arteriosclerotic process brings about a stenosis of the vessel, but the complete occlusion results from thrombosis. They have not encountered a case in which thrombosis developed in the absence of sclerotic arteries. The sclerotic patches in the arteries are multiple, various branches of the right and left coronary being involved at the same time. The presence of stenosing endarteritis in both right and left coronary arteries enhances the myocardial damage that results from nutritional disturbances. A unilateral stenosing endarteritis may progress to a considerable degree without causing myocardial damage or cardiac manifestations. If the developing stenosis progresses slowly, the anastomotic circulation between the right and left coronaries compensates for the vascular derangement, when one coronary alone is seriously affected. Rapidly occluding processes as obtained in thrombosis induce more serious myocardial disturbances than the slowly progressive and compensating stenoses associated with chronic endarteritis. The stenosing arteriosclerosis appears to have its beginning either in a primary endarteritis or in an intimal degeneration followed by endarteritis. Although rheumatic lesions of the arteries may play a part in the origin of the sclerosis, they were unable to demonstrate this association in their specimens. Nor were they able to demonstrate a direct relation between syphilis and coronary sclerosis. Furthermore, in this discussion they do not include the stenosis arising at the aortic entrance to the coronary arteries resulting from syphilitic aortitis. The manner of distribution of the scleroses does not support the contention that the arterial lesions are the result of mechanical stresses due to unique branching of the coronary arterial system. The factors in the causation of endarteritis and atheroma of the coronary arteries are still undetermined.

Sickle-Cell Anemia.—Scriver and Waugh report a case of sickle-cell anemia observed in Canada and show that the number of sickle cells in the blood in vivo may be varied by the change of the partial oxygen pressure, that this is a reversible reaction, and that sickling takes place when the oxygen pressure falls below a pressure of 45 mm. of mercury. These observations agree with those previously noted in vitro by Hahn and Gillespie. An explanation is advanced for the presence of large aggregations of sickle cells in organs obtained at necropsy or at operation.

Multiple Adenopapillomas of Stomach. — Reports of eighty-eight cases of multiple gastric adenopapillomas have been found by Ackman in the literature, and one more case is added. The lesion is classified pathologically under two heads: polyadenoma "polypeux" and polyadenoma "en nappe." Polyadenoma "en nappe" is much rarer, only seven cases having been reported previously. The eighth is described here. The condition is generally thought to be inflammatory in origin, though a congenital origin and a familial tendency have been noted by several writers. The experimental production of these tumors by irritants is significant. There is no characteristic symptomatology, though epigastric pain is the most frequent symptom. Hematemesis is occasionally the first sign. Of laboratory diagnostic aids the roentgenogram probably comes first, though even this is apt to be misleading. Achlorhydria is an almost constant finding and when combined with myxorrhea is considered very suggestive. Malignant transformation is quite common but is rarely multiple. The latter fact is thought to be due to immunity. Their case showed, in addition to a large carcinoma, malignant changes in the stalk of a pedunculated adenopapilloma at the pylorus. Treatment should be surgical.

So-Called Cyanide Rash in Gold Mine Mill Workers. —Braddock and Tingle discuss a dermatitis that occurs among workers in mill plants where the cyanide process of gold extraction is used. It is suggested that the condition may be a simple dermatitis due to irritation by a strong caustic and not to poisoning by cyanide, and that the immediate exciting agent is probably lime, whether as the oxide in the dust flying round the slaking barrel or as a strong solution of the hydroxide in the mud of the mud press.

Dust Inhalation and Iron Ore Mining. — Collis and Goadby assert that prolonged inhalation of dust from iron ore does not originate miners' phthisis nor any tendency to pneumonia, but it does set up bronchitis; it causes shortness of breath and impairs chest expansion without, however, setting up troublesome symptoms; it is associated with roentgen shadows indicative of fine diffuse fibrosis; and it originates definite generalized pulmonary changes of a fibrotic type which impair the usefulness of the lungs.

Modern Conception of Arthritis.—Cecil states that in rheumatic fever the most important predisposing factor is environment. Rheumatic fever is a rare disease among the well-to-do. It is extremely common among the children of the poor. This increase of susceptibility in the poor is probably a combination of improper diet and exposure to cold. The well-to-do are better fed and better clothed and escape infection. Probably another predisposing factor is exposure to a carrier of the rheumatic fever virus. This may be heredity, but contagion may be an important factor. In both rheumatic fever and infectious arthritis, focal infection is of vital significance. Statistics show that rheumatic fever cannot be prevented by the removal of all foci of infection, but the incidence is considerably reduced. Other factors are influential in the etiology of infectious arthritis. Among them, nervous or emotional shock should be stressed. It is surprising what a large percentage of these patients give a history of overwork or some emotional disturbance just prior to the onset of arthritis. Other factors, such as trauma and exposure to cold and dampness, sometimes provoke the first attack. Cecil has seen a number of butchers who say they have contracted arthritis from too many trips to the refrigerator. In hypertrophic arthritis, overweight and advancing years are the two great predisposing agents. Heredity also plays an important part. Nearly every patient with Heberden's nodes will give a history of a mother or father who was afflicted with the same condition.

Synovial Fluid in Health and in Disease: Arthritis.—According to Forkner, a sugar content under 60 mg. per hundred cubic centimeters is almost always associated with infection in the joint. A sugar content under 45 mg. is strong evidence in favor of the presence of pyogenic organisms. A p_H value in the neighborhood of 7.0 is strong evidence in favor of the presence of bacteria. A p_H value under 7.0 is almost certain to be associated with the presence of pyogenic organisms. An icteric index over 5.5 is almost invariably a sign that trauma is playing or has played a significant part in the etiology. A positive Wassermann reaction in the joint fluid associated with a negative reaction in the blood is strong evidence in favor of syphilitic arthritis. A positive Wassermann reaction in the blood associated with a negative reaction in the synovial fluid probably represents good protection against the ultimate development of syphilitic joint disease. A high leukocyte count of 11,000 or more cells per cubic millimeter associated with 60 per cent or more of granulocytes in the synovial fluid of a patient with chronic nonspecific arthritis is likely to be associated with the presence of a positive culture of attenuated organisms. A leukocyte count in the joint fluid of 5,000 or fewer cells together with less than 50 per cent of granulocytes in a patient with chronic nongonorrheal arthritis is likely to be associated with a negative culture of the fluid. The presence of large numbers of red blood corpuscles in the synovial fluid of a patient with arthritis is evidence against chronic nongonorrheal, tuberculous, syphilitic or acute septic arthritis and is in favor of trauma as the etiologic agent. Animal inoculation is of value in the diagnosis of syphilitic arthritis occurring early in the disease.

Basic Diet for Chronic Arthritis.—Snyder and Traeger assert that the regulation of diet is of utmost importance in the treatment of chronic arthritis. Each patient should be placed, for a short period, at the beginning of treatment on a basic diet, which is then regulated and adjusted to fill the individual requirements of the case. The regulation of the diet depends largely on such factors as the patient's general condition, weight, blood on chemical examination, and clinical progress. The basic diet must have low caloric value, low carbohydrate, protein and purine values, adequate vitamin content, elasticity and availability. A basic diet for chronic arthritis is presented.

Use of Drugs in Treatment of Atrophic Arthritis.—Young concludes his review by stating that when drug treatment is instituted it should be done with the definite purpose of correcting some phase of the patient's illness. In order to do this, one must know the patient clinically and understand the pharmacology of the drug to be used. Drugs used in this manner in conjunction with other methods, as indicated by the condition of the patient, will be of distinct value and contribute toward the improvement that can be obtained in a large percentage of these patients when properly treated.

Treatment of Chronic Infectious Arthritis by Sympathetic Ganglionectomy.—Hench et al. believe that resection of sympathetic ganglions and trunks is not applicable to all forms of arthritis, nor is it useful in all stages and degrees of chronic infectious arthritis. In this experimental stage it is the authors' impression that it is of definite value in certain carefully selected cases. It seems to be a justifiable procedure in these selected cases when all other reasonable measures have failed. Used properly, but not delayed too long, it may, by maintaining increase in temperature, circulation and perhaps metabolism of the more distal joints of the extremities, induce a stage of compensation in the arthritic disability that cannot be produced otherwise. Their final opinion regarding the proper selection of cases for the operation, and its value in these cases, cannot yet be expressed.

Results of Treatment of Arthritis.—The results of treatment of 108 cases of type II arthritis by the orthopedic clinic of the Stanford University School of Medicine are noted by Exelby. Sixty-three of the patients received emetine. Of 134 cases of type II arthritis in which stool examinations were made, 27 per cent showed positive results. Of 117 cases of type II arthritis in which dental examinations were made, 58 per cent showed one or more dead or abscessed teeth. Of the sixty-three patients treated with emetine, 8 per cent received complete relief from symptoms, 19 per cent considerable relief, 19 per cent slight relief, 22 per cent no relief, and the results are not known in the remaining 32 per cent. There is no correlation between the duration of the process and the success of treatment in this series of cases. The complete 12 grain (0.8 Gm.) course of emetine produced more favorable results than did shorter courses of emetine. Of fifty patients who received a full course of emetine, 58 per cent showed some toxic symptoms; 32 per cent showed moderately severe or severe reactions. Women seem somewhat more susceptible to emetine intoxication than do men. The age seems to affect the susceptibility but little. The fall in blood pressure found in almost all persons taking the emetine treatment seems not to be related in degree to other toxic manifestations of the drug.

*Intestinal Obstruction: Unusual Case. B. K. Sikand and E. V. Claydon.—p. 422.

Bacillus Coli Infections.—Wilkinson discusses a *Bacillus coli* infection of the urine, a condition which he says is frequent in children, commoner in girls than in boys, appearing in acute, chronic and recurrent forms, but which is relatively seldom fatal. This condition has been called pyelitis, but it is not always part of a septicemia or evidence of a nephritis. It is hardly likely that a severe septicemic condition in children, with renal infection and possibly abscess formation, could have a mortality as low as 3 per cent after the age of 2, and it is significant that the collection of seventy-eight postmortem records took no less than twelve years at two large children's hospitals, whereas, clinically, *B. coli* infections are of common occurrence.

Bacillus Coli Infections.—In Nabarro's experience, infections with *B. coli* in children are by no means rare; they often get well spontaneously; at other times they become chronic or tend to recur. In the chronic and recurring cases cystoscopy, pyelography and, if necessary, catheterization of the ureters should be carried out in order to ascertain whether there is any abnormality present to account for the clinical condition. These surgical procedures should not be so long delayed that the child's kidneys are found to be irreparably damaged when the biochemist makes an investigation of the blood urea and of the renal function. Every case of urinary tract infection should be investigated by a team of five—a physician, a surgeon, a bacteriologist, a biochemist and a radiologist and, if the patient should unfortunately die, then also a pathologist to hunt carefully for anatomic abnormalities. If this were always done these cases would be more thoroughly and systematically investigated than in the past, and the results would be better than have hitherto been obtained.

Intestinal Obstruction.—Sikand and Claydon relate the case of a man who was suddenly seized with acute abdominal pain after eating a heavy meal. He vomited at the time and continued to do so throughout the night. The following morning he was markedly collapsed, with a pinched face and a pulse uncountable and imperceptible at the wrist. The respiration rate was 22 and the temperature 97.7 F. The abdomen was distended, rigid and tender, especially in the epigastrium; movements were practically nil. The patient had not passed urine and the bowels had not been open since before the onset of the attack; a gentle enema gave no result. The abdomen was opened by a midline subumbilical incision. Loops of slightly distended but much engorged small intestine presented, and the abdominal cavity contained a considerable amount of blood-stained fluid. The trouble was eventually traced to the sigmoid loop, which was long and mobile, and which had swung across the abdomen to the right side, where it had herniated into a large retrocecal fossa. It was tightly gripped in this position by a tense peritoneal band extending from the abdominal wall behind the cecum to the lower end of the attachment of the mesentery of the ileum. The sigmoid loop was tightly stretched but was not twisted. It was found that in taking up this position it had come to lie across the mesentery, obstructing the blood supply of the ileum for six or eight feet to within one foot of the ileocecal junction, where the structures, including the appendix, were quite normal. The constricting band of mesentery was divided. Continuous intravenous saline solution was given throughout the operation, but at this stage life was almost extinct and it was considered advisable to close the abdomen. The patient died about one hour later.

Melanogenesis. G. H. Percival and C. P. Stewart.—p. 497.
*Analogy of Black Colostrum to Melanidrosis: Colored Milk and Colored Sweat. D. M. Greig.—p. 524.
*Nature and Structure of Suprarenal Cortex. J. P. M'Gowan.—p. 545.

Analogy of Black Colostrum to Melanidrosis.—Greig points out that in sweat secreted under abnormal conditions there may be on rare occasions some constituent which on oxidation by air yields a black pigment; in colostrum there may be on rare occasion some constituent which by the action of oxidase, which colostrum is known to contain in excess, yields a black pigment. The change in the sweat takes place on the surface; the change in the milk occurs intraductally. The sudoriparous and the mammary glands have the same phylogeny and similar physiologic principles modify and control their function. The conclusion is justifiable that there is a close analogy between black colostrum and melanidrosis.

Nature and Structure of Suprarenal Cortex.—Certain appearances of the suprarenal of fowls suffering from leukosis have led M'Gowan to make deductions regarding the structure and function of its tissues. The occurrence of a myelocytic proliferation in the sinusoids would seem to be an instance of the general rule that myeloid tissue is formed in endothelial or subendothelial situations in veins. The cortical nodules are considered to be periarterial structures and to be formed in the mature gland by the development of the reticulo-endothelial elements situated in the sheaths of arterioles. The cells of the cortex, therefore, are mesoblastic in origin. The relation of the function of the cortex to that of the sex glands is discussed.

*Fahraeus's Test for Suspension Stability of Erythrocytes in Tuberculosis Practice. J. Crocket.—p. 106.
Two Recent Cases of Typhus Fever in Glasgow. C. M. Smith.—p. 117.

Fähraeus's Test for Suspension Stability of Erythrocytes.—Crocket believes that the sedimentation test is a simple and satisfactory means of determining the degree of toxemia resulting from the absorption of products of destruction. The test is particularly useful in tuberculosis; taken on several occasions, it helps one to assess the fitness of the patient and points to the probable course that the disease will take. The test should not be taken by itself but used along with other means of investigation, as its results are not parallel with the facts of the case in more than 85 per cent of the cases. The test is sufficiently simple and rapidly carried out to be adopted in the consulting room in general or dispensary practice.

Study of Yeasts by Complement-Fixation Test.—Stone asserts that by using a saline washing of the yeast as antigen the complement-fixation test can be applied in the identification of various members of the yeast and sporothrix groups. Specimens of thrush (*Oidium albicans*) obtained from ten successive cases gave identical results. By the complement-fixation test, all belong to one serologic type. Specimens of yeasts obtained from other sources have been studied and are shown to fall into five types. The sporothrices of Beurmann and Schenck appear to be identical, and quite distinct from yeasts so far studied. The sporothrices of Gougerot and Jeanseln appear to be identical with black yeasts obtained from other sources.

Radiographic Study of Coronary Arteries.—Jones describes his method of injecting the blood vessels of the heart with barium sulphate for purposes of radiologic study and then relates the results of his study of three cases. He says that the occlusion of the artery to the auriculoventricular node is a much more serious lesion than the occlusion of a branch of a similar size on the lateral aspect of the left ventricle. The larger the artery occluded, the greater is the liability to intracardiac thrombosis, aneurysm and rupture. Coronary anastomosis becomes much more extensive with increasing age. It is clear, therefore, that the coronary system of persons over 50 may be capable of adjusting itself rapidly to any sudden vascular alterations. Compensatory anastomosis is well developed when the rate of occlusion has been slow, and the myocardium is normal in those cases in which occlusion has been gradual. Low blood pressure tends to delay the opening of new anastomotic channels. Chronic interstitial myocarditis is a common occurrence prior to infarction and that is due to the coronary sclerosis that existed prior to the final occlusion. The presence of fibrosis is serious in that the finer arterioles are obliterated and thereby the anastomosis is much diminished. Canalization of the thrombus will assist to a certain extent in reestablishing the blood supply.

33: 519-582 (Sept.) 1930

*Cerebral Lesions in Whooping Cough. W. Mikulowski.—p. 519.
*Pneumonia in Early Infancy. E. Cassoute, R. Poinso and Zuccoli.—p. 546.
Eczema in Nurslings. R. Froycz.—p. 550.

Cerebral Lesions in Whooping Cough.—Mikulowski condemns the common opinion that whooping cough is merely a cough lasting six weeks and accompanied by vomiting. It is in his opinion one of the most frequently fatal diseases of childhood. The cough itself, in fact, is merely a defensive reflex reaction of the organism to the general infection; laryngeal contractions and convulsions often accompany, precede or even replace the cough. Whooping cough is often accompanied or followed by cerebral lesions, especially hyperemia, edema of the brain and the meninges and venous thrombosis. These cerebral lesions are the result of the toxic and infectious influence of the pertussis virus on the brain and the nervous and vascular system and are closely connected with pulmonary lesions arising from a center of inflammation in the lungs.

Pneumonia in Early Infancy.—Cassoute et al. are convinced that pneumonia occurs in nurslings. Typical cases present the same symptoms that accompany pneumonia in older patients. Although the helmet-shaped shadow revealed by roentgen examination is present also in chronic syphilitic pneumopathies, tuberculous pneumonia and pseudolobar bronchopneumonia, the syndrome and development of these diseases is so different that they can be easily distinguished from the typical forms of pneumonia. However, certain atypical or prolonged forms of pneumonia in which the evolution of the disease is longer and the symptoms more irregular are difficult to distinguish from pseudolobar bronchopneumonia or splenopneumonia, although their resemblance to the typical forms is marked.

*Subhepatic Pain in Peptic Ulcer. A. Cade and M. Milhaud.—p. 461.
*Concealed Cancer of Esophagus. S. Bonnamour and P. Pichat.—p. 469.
Classification and Action of Cholagogues. M. Milhaud.—p. 477.

Pain in Pyloric and Duodenal Ulcers as Cause of Incorrect Diagnosis.—Cade and Milhaud show that the localization of the pain produced by pressure is of little pathognomonic significance in the diagnosis of pyloric and duodenal ulcers, and in distinguishing between such ulcers and chronic cholecystitis. Three cases are cited in which pain was felt in he region of the gallbladder and in which other symptoms eemed clearly indicative of cholecystitis; but operation revealed duodenal ulcers. Unfortunately dyspeptic symptoms, gastric chemism and roentgen examination give no better results. The best advice that can be given, therefore, is not to forget that here is a possibility of pyloric or duodenal ulcer even though he syndrome indicates cholecystitis.

Concealed Forms of Cancer of Esophagus.—Bonnamour and Pichat point out that dysphagia is not always present in cancer of the esophagus, a fact not as yet well known because n most of these cases the diagnosis is made only on postmortem examination. The principal forms of cancer of the esophagus without dysphagia are: (1) gastric; (2) cachetic and anemic; (3) bronchopulmonary; (4) mediastinal and laryngeal, and (5) metastatic. The diagnosis is difficult when dysphagia s absent; in fact, one must usually first consider the possibility of cancer of the esophagus and then look for symptoms, the most important of which are frequency, precocity and minimal mount of vomiting, hiccups, excessive secretion of saliva, leuropulmonary signs and roentgenoscopic mediastinal obscurity.

Vaccinotherapy in Bronchial Pneumonia Among Children.—Gardère cites clinical observations and statistics to show hat while vaccinotherapy in bronchopneumonia among nurslings does not noticeably affect the prognosis, nevertheless the mortality rate is slightly lowered by its use. It is well, therefore, to use vaccination regularly in addition to other methods of treatment in order to give children every possible chance or recovery. When vaccine cannot be secured, proteinotherapy n the form of subcutaneous injection is the best substitute.

Treatment of Severe Inflammation Caused by Lower Wisdom Tooth. M. Dechaume.—p. 222.

Ocular Complications Caused by Vaccine.—Toulant hows that dangerous complications may develop from infection of various parts of the eye with vaccine, since the eye does not participate in the general immunity acquired by previous vaccination. All who assist in the care of vaccinated children, and those who assist in the preparation of vaccine, should take special precautions to protect their eyes from contact with the serum itself or with infected material. The author mentions a severe case of keratitis which developed from a father's rubbing his eyes after caring for his child who had been vaccinated. The infection may be localized in the eyelids, the conjunctiva or the cornea. Vaccinal keratitis is the most dangerous of the three, frequently lasts from six months to a year, and often results in the complete loss of one or both eyes. No particularly successful treatment has yet been found to combat this infection. The best procedure, therefore, is for all those in contact with vaccine to exercise all possible care. Every one should have at hand a 1 or 2 per cent solution of silver nitrate, or an eyewash of strong silver protein (10 per cent) or of chloramine (2 per cent) to be used immediately as an antiseptic if infection of the eye is suspected.

Indications for Operation in Acute Mastoiditis.—The three chief symptoms to observe in determining the advisability of a surgical operation in cases of mastoiditis are pain, temperature and discharge. If in a case of otitis, after the opening of the tympanum, the pain does not disappear in a short time but persists either steadily or spasmodically, and if palpation reveals soreness in the mastoid region, one has a right to suspect the development of mastoiditis. Although the pain alone is insufficient evidence, under these conditions the temperature curve is usually found to deviate from the normal either by a steadily increasing temperature, by failure of the fever developed earlier to disappear after the opening of the tympanum, or by a marked irregularity of temperature on different days or from morning to evening. The discharge also will probably show irregularities; in some cases it shows a marked increase while in others it stops and starts from one day to the next. Therefore, while no one of the three symptoms of pain, fever or irregularities in discharge is sufficient grounds for an operation, careful clinical observation of all three makes it possible to determine definitely when surgical intervention is necessary. Liébault makes a special point of the fact that the symptoms formerly considered decisive (retromastoid puffiness, then swelling in this region and later redness and fluctuation) appear too late to have any diagnostic value, since they indicate not that mastoiditis exists but that it has existed.

*Treatment of Poliomyelitis with Serum of Former Patients. A. Netter.—p. 1169.
Preparation and Handling of Radioactive Bodies. F. Heim de Balsac, E. Agasse-Lafont and A. Feil.—p. 1171.
Proof of Existence of Traumatic Cholecystitis. G. Parturier.—p. 1173.
Perforations of Postabortal Infected Uterus. P. Monod and E. Kiraly.—p. 1175.
*Accidental Parasitism of Digestive Tube by Tyroglyphus Farinae. J. Quérangal des Essarts.—p. 1176.

Treatment of Poliomyelitis with Serum of Former Patients.—Netter advocates the use of serum of former poliomyelitis patients in the treatment of the disease. This serum is an efficacious means of preventing the evolution of poliomyelitis in its preparalytic stages and of arresting paralysis in the later stages. When former patients are difficult to find, a neutralizing serum can often be obtained from the blood of healthy adults who have been in contact with or near poliomyelitis patients, or even from the blood of adults from localities where cases of poliomyelitis have formerly existed.

Accidental Parasitism of Digestive Tube by Tyroglyphus Farinae.—Quérangal des Essarts, in the course of almost a thousand coprologic examinations, found *Tyroglyphus farinae* eight times. The occurrence of this acarid seemed entirely accidental and isolated, as further examinations of the stools of the same patients revealed no more traces of the parasite or its eggs. The author describes briefly the eight cases cited.

Prognostic Value of Variations of Weight in Pulmonary Tuberculosis. J. Caussimon.—p. 1185.
*Origin and Practical Importance of Leukocytosis, Fever and Azotemia as Postoperative Reactions. D. Berceanu, M. Slatina and Albulesco.—p. 1187.

Importance of Leukocytosis, Fever and Azotemia as Postoperative Reactions.—Leukocytosis as a postoperative reaction occurs to a degree corresponding with the activity of the hematopoietic organs of the patient; this activity depends on the disease from which the patient is suffering, his age and his physical resistance. Postoperative leukocytosis causes companion reactions of fever and azotemia. From these facts Berceanu et al. draw the following conclusions: *Intense leukocytosis with high fever and pronounced azotemia indicates general physical vigor and activity of the hematopoietic organs; hence an extremely favorable postoperative prognosis. Likewise* moderate leukocytosis with correspondingly mild fever and azotemia suggests a moderately favorable prognosis. Little or no leukocytosis may be taken as a warning of unfavorable postoperative evolution.

*Tourniquet Capillary Resistance Test and Familial Serotherapy in Hemorrhagiparous Conditions. P. Chalier and R. Froment.—p. 1201.
Periodic Vomiting with Acetonemia. G. Leven and R. Leven.—p. 1202.

Tourniquet Capillary Resistance Test and Familial Serotherapy in Hemorrhagiparous Conditions.—Chalier and Froment describe a case of severe purpura in the course of ordinary diphtheritic angina revealed by a tourniquet capillary resistance test, which is invaluable in determining hemorrhagiparous conditions. In the treatment of such conditions the authors find human serotherapy extremely effective, especially when serum from the blood of members of the same family is used. Several of their patients who were suffering from hemorrhages both in diphtheritica angina and from other sources have been cured by subcutaneous injections of serum from the blood of a relative when injections of serum coated with gelatin and animal blood serum had been wholly inefficacious.

*Advantages of Phrenicectomy Combined with Pneumothorax. C. B. Udaondo and A. Vadone.—p. 493.
*Pathogenesis and Treatment of Mega-Esophagus. P. Guns.—p. 505.

Advantages of Phrenicectomy Combined with Pneumothorax.—Udaondo and Vadone advocate the use of phrenicectomy as a subsidiary to pneumothorax in certain cases in which this method perfects and completes the action of the pneumothorax. This use of phrenicectomy has the following advantages: (1) prolonged duration of the pulmonary collapse, reabsorption of the insufflated air being balanced by the ascent of the diaphragm; (2) prolonged interval between insufflations; (3) ideal conditions for pulmonary reexpansion, because of the reduction of the pleural cavity, after abandoning the pneumothoracic cure, and (4) more complete pulmonary repose. However when the diaphragm is fixed by obliteration of the costodiaphragmatic sinuses, the operation is contraindicated because the ascent of the diaphragm is impossible. For this reason it is best to proceed first with the pneumothorax and then ascertain either by roentgen examination or by pleural pressure whether a phrenicectomy is indicated.

Pathogenesis and Treatment of Mega-Esophagus.—Guns conducted a series of experiments to determine the pathogenesis of mega-esophagus. He found that the source of this disturbance is in the autonomic nervous system. A phrenocardiospasm is first produced. This is replaced by a cardiospasm under the mechanical influence of the weight of the substances in the esophagus. As the mass directly above the seat of the spasm increases, it fatigues the diaphragmatic muscles and causes the contracture to take place wholly in the cardia. This mechanical action is amplified by the peristalsis. There have been many opinions as to treatment. However, at present most physicians prefer to practice dilation of the cardia to 5 or 6 cm. in diameter by means of bougies. Guns has achieved favorable results by using strychnine along with dilation.

Congenital Pseudarthrosis of Tibia. M. Camurati.—p. 1.
*Arthritis Due to Bacterium Coli-Commune. E. Codeleoncini.—p. 163.
Remote Results of Free Autoplastic Bone Transplants in Pseudarthrosis of Femoral Diaphysis. F. Melina.—p. 174.

Arthritis Due to Bacterium Coli-Commune.—Codeleoncini's patient, a coachman, aged 67, was a man whose general health was bad, which explains possibly in part the unusual site of the colibacillary infection. The patient developed a pain of moderate intensity in the left knee, which appeared and disappeared without evident cause. The pain increased later but retained the same character. The part was neither red nor swollen. The patient had recently lost from 8 to 11 pounds (3.6 to 5 Kg.). Later a slight edema of both lower limbs developed. In the urine a considerable quantity of colibacilli were found. The clinical diagnosis was subacute arthritis of the left knee and tumor of the prostate. The swelling involved later the lower third of the thigh and the uppermost third of the leg. The normal depressions of the patellar and parapatellar regions had, in part, disappeared. Roentgen examination of the knees revealed nothing pathologic. A month after admission to the hospital, the cavity of the left knee was opened and about 300 cc. of thick, yellow and thready pus was evacuated. Numerous bacilli were found, which were identified as colibacilli. The patient was somewhat relieved; the pain nearly disappeared. Two days later there was a marked rise of temperature with chills and the knee again became painful. About 100 cc. of the same kind of pus was evacuated. The bacteriologic examination gave the same results as before. Seven weeks later, a general intoxication due to cancerigenic metastases and altered metabolism developed and death occurred three months after the first evacuation. In view of the small number of cases that have been reported, the author hesitates to advance any theory to explain how colibacilli became localized in the left knee but thinks the low state of health of the patient favored such localization. He is inclined to assume that, owing to the ubiquitous nature of colibacilli, such infections may not be as rare as is supposed. As for the treatment of arthritis due to colibacilli, surgical and orthopedic methods are most important. Also autovaccinotherapy, when indicated and possible to carry out, if begun promptly and followed up with rapidly increasing doses, is valuable. Of late, a great deal is said about d'Herelle's bacteriophage. In France, Fisch's vaccine and Vincent's anticolibacillary serum are much used. Antiseptics, given intravenously (methenamine, 40 per cent solution), or applied locally (for example, compound solution of iodine or solution of chlorinated potassium carbonate [Javel]) sometimes give good results.

*Biologic Diagnosis of Pregnancy by Aschheim-Zondek Method. G. Addessi.—p. 449.

Diagnosis of Pregnancy by Aschheim-Zondek Method.—Addessi, after referring to other methods proposed for the biologic diagnosis of pregnancy, considers the value of the Aschheim-Zondek test. From the application of the test to forty-eight pregnant women, in various months of gestation, there were forty-seven positive results and one negative result. Of eight extra-uterine pregnancies, six gave a positive reaction and two a negative reaction. In sixteen puerperal women it was demonstrated that the hormone of the anterior lobe of the hypophysis is eliminated with relative rapidity, for after the sixth day since the birth the reaction has always been negative. In twenty-four controls consisting of women of various ages with various gynecologic disorders, inflammatory conditions of the adnexa and parametrium, healthy men of various ages, and others, the result of the test was always negative. The author emphasizes the importance and the utility of the test, especially in those cases of initial pregnancy in which the clinical examination ofttimes does not furnish sure results.

*Cervical Spina Bifida Occulta and Its Late Clinical Symptoms. G. Reggiani.—p. 677.
Subcutaneous Leiomyofibro-Angiomatosis: Case. C. Malossi and G. Gelli.—p. 729.

Late Clinical Symptoms of Cervical Spina Bifida Occulta.—Observations in a case of amyotrophic paralysis of the upper limbs in a man, aged 48, in which the roentgen examination revealed a split in the seventh cervical vertebra, furnished Reggiani the occasion to survey and discuss the so-called late syndromes of cervical spina bifida occulta. After describing and discussing the diagnostic aspects of the case, he considers observations made by others in cases of cervical spina bifida occulta. Cases in adults are discussed in their clinical manifestations and in their genesis. From comparisons drawn between the observations previously made and his own case, the author concludes that a malformation of this nature does not present peculiar clinical aspects. He admits, however, the possibility of syringomyelic syndromes, paralysis and muscular atrophy being among the anomalies of primary development. Having found in the observed case data that pointed to syphilitic infection, the author thinks that such a factor may intervene as an occasional cause in the determination of the syndromes observed in spina bifida occulta in the adult.

Mixed Osteohypertrophic Nevus of Left Maxilla, Chin, Neck and Left Half of Tongue: Case. P. Lacchia.—p. 617.
Scurvy in Infant: Case. G. Marcelli.—p. 626.

Arneth and Schilling Formulas in Exanthematic Diseases and Diphtheria.—Nervi made both the Arneth formula and the Schilling blood count in seven normal children as controls and in four groups of children with diphtheria, scarlet fever, measles or varicella. The blood for examination from the stricken children was taken in one group at the peak of the disease and in the other group at three different periods (at the peak of the disease, at the descending period from the crisis to the convalescence and in late complete convalescence). The author presents his results in tables. The current theories are briefly reviewed. In normal children the figures given by the Schilling blood count agreed with those of the Arneth formula. In the Schilling blood count the neutrophils are divided into two groups: neutrophils with only one nucleus and polymorphonuclear neutrophils. While modifications of the neutrophilic picture were observed in the Arneth formula, the author observed that, in infectious diseases, cells of one or of two nuclear segments predominate, that is, there is a shifting of the neutrophils to the left. This shift curve has no relation with the seriousness of the condition and it is more marked during the period from the crisis to the convalescence, while it returns almost to normal in complete convalescence. The author considers that in infectious diseases the bone marrow is under the influence of a toxic or infective stimulus which compels a rapid production of young cells. The predominance of young cells is more marked in scarlet fever, is less in measles, is still less in diphtheria and is almost insignificant in varicella. In the determination of the Schilling blood count the author considers the young forms of neutrophils as regenerative cells that improve the condition of the blood. In infectious diseases, young forms of the type of the regenerative cells with a single nucleus predominate in the circulation during the acute period. In the period from the crisis to the convalescence, an intense regeneration of the blood takes place, while few myelocytes and metamyelocytes appear in the circulation, and in complete convalescence the blood returns to normal or almost normal. The author could not find even in the most serious forms of infections a high percentage of immature cells. He concludes that the value of the neutrophilic picture of Arneth is more theoretical than practical in the diagnosis and prognosis of infectious diseases. The formula does not point out either the nature or the intensity of the stimulus of the bone marrow. The Schilling blood count gives a clearer idea for the interpretation of the picture given by infectious diseases, but, if the grave symptomatology of these diseases is taken in consideration, even the Schilling blood count is of but little value. However, the knowledge derived from these two formulas on the conditions of the blood during infectious diseases should be taken as the basis for a qualitative and quantitative estimation with regard to the rôle assumed by the bone marrow and the peripheral blood in the evolution of several infections.

Changes of Sugar Metabolism in Peptone Shock with Circulatory Insufficiency. E. Schiff, H. Eliasberg and A. Mazzeo.—p. 697.
*Rhythm and Action Current of Heart in Typhoid in Children During Shock Caused by Antityphoid Vaccine. M. Gerbasi.—p. 709.
Anemia and Idiopathic Hypertrophy of Heart in Early Childhood: Case. E. Frola.—p. 733.

Rhythm and Action Current of Heart in Typhoid During Shock Caused by Antityphoid Vaccine.—Gerbasi studied the behavior of the rhythm and action current of the heart during the shock caused by the intravenous injection of lysed typhoid vaccines in fourteen children with typhoid, aged from 2 to 13 years. All the patients recovered. Electrocardiograms were taken immediately before the injection, during the crisis of the reaction caused by the vaccine and after the disappearance of the reaction. In seven of the children the electrocardiograms were repeated during complete convalescence when the general condition of the patients had markedly improved. The administration of any medicament that could in any way interfere with the results, or act even indirectly on the heart, was suppressed during a period preceding and including the observations. It was a constant observation that after the intravenous injection of typhoid vaccine the waves in the electrocardiograms were smaller in cases in which the activity of the heart was more seriously affected than in those cases in which the functioning of the heart was less seriously impaired. That is, in the first group of patients the phenomena of generation of the action current of the heart (or nervous stimulus) was less intense than in the former group. Examination of the electrocardiograms proved that the shock that follows the intravenous injection of antityphoid vaccines causes an activation of the electromotive force of the heart. It also causes alterations of different form and intensity of the functions of the heart. These alterations are in relation with the more or less serious condition in which the heart is under the influence of the disease. They may be overcome when the functioning of the heart is reasonably good, but otherwise they may endanger the patient's life. Hence the advisability of considering the alterations caused by typhoid not exactly as a contraindication for the use of intravenous injections of antityphoid vaccines, when they have not caused serious disturbances in the functioning of the heart, but as a clear indication of the caution necessary in the use of the vaccines in patients in whom the functioning of the heart is impaired.

*Rigid Fixation of Jaws Due to Forward Luxation: Arthroplasty. A. Battista.—p. 1122.

Rigid Fixation of Jaws Due to Forward Luxation: Arthroplasty.—Battista describes in detail his operation on a boy, aged 9, who, as a result of a fall from a wall six feet high, in which he struck on his chin, developed a rigid closed fixation of the jaws due to forward luxation of the mandible. The author made a vertical incision beginning a finger's length from the tragus. Crossing the zygomatic arch, the incision extended 5 cm. in the temporal region. A second (transverse) incision was made, starting from a point from which it formed a right angle with the first incision and running along the lower border of the zygomatic arch. As the soft parts were reached they were dissected downward so as to avoid the facial nerve; thus the bony skeleton was reached. The displaced head of the condyle, held tightly in the zygomatic arch at about the junction of the temporal and the upper maxillary processes, was easily recognized by its different shade of color, due to its enveloping cartilage. The neck of the condyle was isolated in order to liberate it from the newly formed tissue—partly fibrous and partly bony. This maneuver, when completed, allowed the author to pass behind it the curved portion of a spatula to protect the internal maxillary artery. He proceeded then with the resection of the condyle and the upper end of the neck. The lower jaw could now be easily mobilized, as the articulation of the opposite side offered only slight resistance. To complete the intervention, the operator resected a rectangular flap of the temporal aponeurosis, with its base in the zygomatic arch, and inserted it in the breech, fastening it loosely with a few sutures about the neck of the condyle, performing thus a partial arthroplasty after the method of Murphy. The tissues were reconstructed and the skin incision was closed, but a narrow strip of gauze was left in the wound as a tampon. The author was ready to perform a tracheotomy in case grave asphyxia developed. The postoperative course was uneventful. On the third day the small tampon was removed, and the wound healed rapidly. For a few days only, the mouth was found open from time to time; then, soon, the patient began to masticate some food—preferably toast. To protect the blood vessels, the author found it useful in his case to use instruments with a rather sharp curve in order to overcome the differential level of the two planes—the surface and the deep-lying tissues. It is important that the curved instrument can be easily inserted behind the condyle and constitutes a strong resistance in the resection procedure. It is useful, too, to apply pressure to the other end of the instrument, after the manner of a lever.

*Nonsurgical Treatment in Ureteral Calculosis. P. Pieraccini.—p. 1156.
Block of Right Branch of Bundle of His, with Auricular Fibrillation. M. Sorrentino.—p. 1161.

Results of Nonsurgical Treatment in Ureteral Calculosis.—Pieraccini concludes: Before subjecting to surgical intervention a patient who presents a calculus wedged in the ureter—especially if the calculus is small and localized in the lower portions of the duct, and is not associated with serious pyelo-ureterovesical inflammatory conditions, it is always indicated to resort to nonsurgical instrumental therapy. Even if the disorder presents all or some of the aforementioned characteristics, one may still hope for a spontaneous emission of the concrement by the administration of diuretics and by subjecting the patient to an appropriate diet. In many statistics in which the percentage of cures effected by instrumental nonsurgical treatment is high, no doubt many cases are considered as successes in which elimination of the calculi would have taken place spontaneously. According to the statistics of Taddei, in cases of recent involvement in which the patients are carriers of small, noninfected calculi in a low position in the ureter, spontaneous expulsion occurs in about 50 per cent of the cases in from six days to one month from the discharge of the patient from the clinic, which interval corresponds closely to the interval between the day on which ureteral catheterization was performed and the day on which the stone was passed.

Siglo Médico, Madrid

86: 57-80 (July 19) 1930

*Functional Synergy of Mastication and Elevation of Upper Eyelid. M. Marín Amat.—p. 57.
*Treatment of Anthrax. F. Jofré de Villegas.—p. 60.
Left-Sided Strangulated Inguinal Hernia Caused by Exertion. V. Fidalgo Tato.—p. 64.

Functional Synergy of Mastication and Elevation of Upper Eyelid.—Marín Amat reports the case of a child, aged 8, whose parents (in whom there was no consanguinity) and six brothers and sisters were normal. The general physical and mental condition of the child was normal, except for a typical synergy of mastication and elevation of the right upper eyelid. The abnormality was congenital, unilateral and accompanied by total ptosis of the eyelid. The eye opened only while the child either opened his mouth or moved his lower jaw to the left. When the eye was opened a paralytic covergent strabismus (caused by paralysis of the external rectus) was observed. The acuity of vision was normal in both eyes. The pathogenesis and treatment of this condition are unknown. An origin, similar to that of other synergies (in which a functional association of the cerebral nerves has been held responsible for the condition) is suspected in these cases. The author reviews the literature and makes reference to a personal observation (previously reported) in which the inverse phenomenon existed (the eye was constantly open and closed only when the mouth was opened). Two hypotheses are given to explain the phenomenon: (1) the intervention of motor fibers arising from the masticator nerve (in the motor portion of the trigeminus), by exercising an abnormal influence on the levator palpebrae superioris muscle, and (2) the presence of an anastomosis between the nuclei of origin of both cerebral nerves between which the functional synergy exists. The only scientific proof is the electrical exploration of the oculomotor nerve in its entire course. The most plausible explanation of the case under discussion seems to be that the functional synergy between the levator palpebrae superioris muscle (innervated by the oculomotor nerve) and the depressor muscle of the inferior maxilla (innervated by the masticator nerve) is caused by the presence of an abnormal peripheral anastomosis between the oculomotor and the masticator nerves.

Treatment of Anthrax.—Jofré de Villegas says that success in the treatment of anthrax depends on early diagnosis and treatment. As soon as anthrax is diagnosed a crucial incision with the thermobistoury is made, giving some points of cauterization around the anthracic area to limit the edema. At the same time 30 cc. of antianthrax serum is given and the dose is repeated the next day. These two first injections of antianthrax serum should be given intravenously to avoid the rapid propagation of the infection in the blood. From the third day of the treatment on, the dose of antianthrax serum should be reduced to 10 cc. daily for the next four days and should be given subcutaneously. The patient should receive also tonic and stimulant drugs to maintain him in the best possible condition. The author has treated eighteen persons with anthrax by the combined treatment of thermocautery and anthrax serotherapy and twelve by the administration of antianthrax serum alone. In each of the groups only one patient died. The author considers that the use of serotherapy should be generalized. By this method the suffering inherent to cauterization and the presence of scars may be avoided. The mortality rate is small (8 per cent in the author's cases).

Treatment and Prognosis in Cerebral Abscesses.—According to Uffenorde, the pathologic anatomy in abscesses of the brain shows that during their treatment complications may be caused by the virulence of the pathogenic micro-organisms, by a progressive encephalitis or by perforation into the ventricle. These complications occur not only in otogenic and rhinogenic but also in traumatic abscesses. The author discusses le Maitre's method and then describes his own procedure. He thinks that his method of opening the abscess and of careful drainage is the more advantageous. He employed it in twenty-four patients, fourteen of whom recovered.

Counteracting Fatal Hemorrhages During Puerperium.—Heim points out that the prevention of fatal hemorrhages is one of the most serious problems in obstetrics. There is danger of fatal hemorrhage in placenta praevia, in premature detachment of the placenta, in lacerations and in atony of the uterus. The author reports the clinical histories of two cases of atony with uterus arcuatus and with lacerations of the cervix uteri. As a result of delayed treatment, death from hemorrhage was imminent. However, the patients were saved by a blood transfusion and by the simultaneous extirpation of the uterus. Occasionally there occur cases of atony in which the conservative methods, even if applied early, bring only temporary improvement. In such instances it is often difficult to decide whether blood transfusion alone will be sufficient or whether the exclusion of the source of hemorrhage by means of total extirpation is necessary. The author thinks that in such cases the vaginal method for removal of the uterus is advisable.

Postmenopausal Hemorrhages as Sign of Cancer of Uterus.—A review of the literature and observations at the women's clinic in Munich convinced Zweifel that about 80 per cent of postmenopausal hemorrhages are caused by cancer. He stresses that, in all cases of postmenopausal hemorrhages, cancer of the genitalia should be thought of and a thorough gynecologic examination should be made. Only when such an examination reveals a different cause for the hemorrhage, may it be concluded that cancer is not present. If not caused by malignant growths of the genitalia, the hemorrhages may be due to erosions, polypi or decubital ulcers. Such causes can be detected by the general practitioner. Whenever the diagnosis is not clear, exploratory curettage should be done. Thorough examination is also necessary in hemorrhages during the menopause because about one third of these are likewise due to cancer. In the conclusion the author emphasizes that in cases of menopausal or postmenopausal hemorrhage it is unpardonable negligence on the part of the practitioner to omit the gynecologic examination. By an expectant attitude and medicinal treatment much valuable time may be lost, whereas an early diagnosis would save the patient's life.

Indirect Injuries from Roentgen Rays.—Lossen reports the case of a man who had been given roentgen treatment on account of psoriasis. Neither during nor after the irradiations did roentgen ulceration become manifest. However, about two years later, the man sustained an injury on the right elbow and an ulcer appeared which represented the aspects of a typical roentgen ulcer and required three years for healing. Some time after that there developed without apparent cause a roentgen ulcer on the left arm. The patient commenced a lawsuit against the physician who had given the roentgen treatment. The first question to be answered was whether the physician was justified in employing roentgen therapy. To this a positive answer could be given, because in psoriasis that is refractory to other treatments roentgen irradiation is considered advisable by most authorities. Investigations regarding the method employed by the physician revealed that the technic also had been correct. The author thinks that indirect roentgen injuries are due to a hypersensibility to roentgen rays on the part of the patient. He then discusses various factors that might be the cause of the hypersensibility. In the conclusion it is pointed out that the causes of such indirect roentgen injuries cannot always be completely determined. Then the author stresses that the patient has to be given instructions regarding the care of the skin after irradiations. When roentgen injuries develop, a specialist should be consulted immediately. The German Roentgen Society makes a special study of the prevention of roentgen injuries.

Disorders Caused by Electric Current That Develops When Different Metals are Used in Dental Work.—Lippmann gives the clinical histories of two patients who had severe headaches, felt weak, were nauseated, lacked appetite, had increased flow of saliva, complained of a burning sensation on the tongue, and found that all foods had a metallic taste. The first patient was toothless. At first she had one gold prosthesis and one india-rubber prosthesis and she felt well. However, when the india-rubber prosthesis broke, it was replaced by one of tin and now the disturbances became manifest. The true cause of the disorders was at first not recognized and a renal disturbance was thought of. The patient remained in bed and did not wear her prostheses and the symptoms disappeared. However, when the prostheses were again replaced the same symptoms recurred. When the true cause was recognized the one prosthesis was again replaced by an india-rubber one, and now the patient gradually recovered. In the second patient a mixture of metals, namely, copper, zinc and lead, had been used for bridge work but they had been incompletely fused. Some copper and zinc crystals remained separate and therefore the alloy did not act as one metal but as two and an electric current developed. The author concludes that if two different metals are present in the mouth an electric current develops. This causes nervous and various other disorders. By electrolysis small portions of the metals disintegrate and it is probable that copper and zinc in ionic form may cause chronic poisoning.

Investigations on Carotin and Vitamin A.—Wolff et al. made animal experiments that confirmed the observations of other investigators, who found that disorders which result from a lack of vitamin A may be counteracted by carotin. However, certain reactions indicated that carotin and vitamin A are not identical. The authors describe the methods that make it possible to separate the vitamin A content from carotin. They determined the vitamin A content and the carotin content in several vegetable and animal products, and they came to the conclusion that in plants vitamin A is either entirely absent or occurs in minute quantities that cannot be detected. The source of vitamin A is carotin. The latter is changed by the animal organism into vitamin A. In animal products, both substances can be detected. Tests showed that egg yolk and butter contain both carotin and vitamin A. Liver and cod liver oil, however, contain almost exclusively vitamin A.

Is Paroxysmal Tachycardia an Allergic Disease?—Luria and Wilensky describe the case of a woman with paroxysmal tachycardia. The anamnesis revealed that the attacks were especially severe following ingestion of large amounts of sweets, particularly raisins and new honey. When the patient was put on a lactovegetarian diet from which all sweets were excluded, the attacks of tachycardia ceased. Later the patient was given honey cake with raisins, and an attack followed. When she was given 100 Gm. of old honey tachycardia did not develop, but the ingestion of 200 Gm. of raisins was followed by a severe attack. The patient was ordered to abstain entirely from raisins and now the attacks did not recur. In order to determine whether the woman was hypersensitive to sweets or carbohydrates, cutaneous tests were made with starch, apples, honey and raisins. Control tests were made on a normal person. Repeated tests revealed that the patient was hypersensitive to extracts from raisins and honey. In the conclusion the authors point out that the observations in this case indicate that perhaps some cases of paroxysmal tachycardia are due to allergy. They recommend the further investigation of this problem.

Disturbances in Carbohydrate Metabolism in Exophthalmic Goiter.—Kugelmann performed levulose tolerance tests on healthy persons and on patients with exophthalmic goiter. In the morning the blood sugar content was tested while the persons were still fasting. Then 100 Gm. of levulose was administered and blood sugar tests were made first after fifteen minute intervals and then after thirty minute intervals. In healthy persons the blood sugar increases slightly but within two hours has again reached the normal level. In patients with exophthalmic goiter the increase is considerable and even three hours after the administration of the levulose the blood sugar is still much higher than normal. On the basis of his observations the author concludes that in the liver in thyrotoxicosis the glycogen depots are depleted, and the liver is no longer capable of changing large quantities of levulose into dextrose and of storing the dextrose. This demonstrates that in exophthalmic goiter there exists a functional disturbance of the liver, which becomes manifest in the pathologic behavior of the intermediate carbohydrate metabolism.

Treatment of Morphinism with Combined Administration of Insulin and Dextrose.—Since several investigators had detected an abnormal carbohydrate metabolism in morphine addicts, namely, a reduced blood sugar content, Anton and Jacobi attempted to treat morphinism with insulin and dextrose. They give case reports of three morphine addicts. Two or three times daily the patients were given 10 or 15 units of insulin. The insulin injections were combined with the peroral administration of 50 Gm. of dextrose. The result of the treatment was that the abstinence symptoms were negligible or were entirely absent, the patients gained in weight and strength and the psychic equilibrium was quickly restored. The authors point out that observations on only three cases do not permit a final evaluation of the method. However, the good results obtained in these cases justify the further investigation of the treatment.

Dry Bed for Infants. Sepke.—p. 1195.

Therapy of Bronchial Asthma.—According to Woldrich the therapy of bronchial asthma should be based on a careful anamnesis. Then skin tests should be made in order to determine the specific allergy. In the majority of cases that came under the author's observation, the anamnesis revealed attacks of pneumonia and chronic bronchitis. Cutaneous tests with a mixture of staphylococci and streptococci gave positive results in 63 per cent of the cases. Other patients showed hypersensibility to dust, pollen, hairs of animals, climatic conditions and foods. The investigations proved that in the majority of cases vaccine therapy was necessary. The author prepared the vaccines either from the sputum or from the nasal secretion. In 37 per cent of the cases the cure was complete and in 45 per cent improvement was noted. In 18 per cent there was no change. Autovaccines brought better results than other vaccines. In cases of dust hypersensibility, attempts were made to remove the cause and the results were generally favorable.

Protein Therapy in Angina Pectoris.—Schmidt is of the opinion that in cases of angina pectoris the favorable effects of muscle extracts and also of heart hormone preparations are not due to hormonal action but represent a protein therapy. The author discusses two forms of angina pectoris. In the first form, which is caused by thrombosis of the coronary arteries, protein therapy is not effective. The second form, designated by the author as "exertion" angina, differs from the first in symptomatology as well as in pathogenesis. Great fear, manifestations of cardiac insufficiency and decrease in the blood pressure are absent in this exertion angina and the pulse is usually especially strong. Observations in many cases of exertion angina convinced the author that it is a sympathetic neuralgic condition that increases as the result of abnormal vasomotor reflexes. The protein therapy influences the sympathetic neuralgia as well as the vasomotor disturbance. The author is of the opinion that in many instances of exertion angina the cardiac plexus may show anatomic changes and it may also be caused by such conditions as syphilis, tuberculosis, nicotinism, metabolic disorders with glycosuria and concrement formations in the urinary and biliary tracts, endocrine disorders, chronic affect conditions, and mental strain. Because of these conditions other symptoms such as sciatica, lumbago, arthralgia and myalgia are often noted. Between the attacks of angina pectoris the chronic neuralgic condition of the cardiac plexus becomes manifest in points that are sensitive to pressure. In the highly sensitive cardiovascular plexus even minor conditions may cause a sympathetic neuralgia. Although neuralgic conditions can be influenced by protein therapy, there is usually a negative phase during which the painfulness increases temporarily. That abnormal vasomotor reflexes are involved in exertion angina is proved by such symptoms as urticaria, wheal reflex, Quincke's edema, chills and spasmodic yawning. Meteorological conditions such as changes in atmospheric pressure, electrical storms and fog as well as psychic factors influence the vasomotor action. This indicates that a certain relation exists between constitutional asthma and exertion angina. And since the beneficial influence of protein therapy has been demonstrated in constitutional asthma, it may be expected that the abnormal vasomotor reflexes in exertion angina may likewise be influenced by protein therapy. The author's experiences with protein therapy are limited to a small number of cases and he therefore refrains from a final evaluation but he recommends this therapy for further investigation. He thinks that complications from protein therapy may be avoided by the use of glyceryl trinitrate.

Disturbances in Vertebral Column After Amputation of Thigh.—Karfiol asserts that pains in the stump in patients in whom the thigh has been amputated have their origin frequently in the vertebral column. They are due to the overburdening that is caused by suspending the prosthesis from the shoulders. To overcome these difficulties it is advisable to attach the prosthesis to the pelvis.

Treatment of Local Infections with Cautery.—Von Bramann reports that at the surgical clinic of the university of Berlin the thermocautery was used during the last two years in 209 cases of local infections; namely, in 102 cases of progressive phlegmon, 66 abscesses, 35 cases of chronic osteomyelitis, 4 cases of emphyema of the joints, 1 case of carbuncle of the kidney and 1 case of pyelonephritis. The technic of thermocauterization in cases of phlegmons or abscesses is as follows: The phlegmon is incised in its entire length, and all cavities and pockets are opened. Then the granulations are removed with a sharp curet. Necrotic tissues are removed with the knife or with scissors. The vessels are seized but are not ligated until after the cauterization. The open wound is cauterized with Hadenfeldt's instrument. The muscular surface is thoroughly seared until an eschar is formed. The under surface of the skin, however, is cauterized only slightly or not at all, so as to avoid gangrene. Tendons, larger vessels, nerves and bones should not be cauterized. Following arrest of hemorrhage the wound is closed with a lacing bandage, which is covered by a second bandage. The dressing should not be changed until eight days after the operation. The pains, which before the operation are usually severe, cease entirely or partly immediately after the operation. The author gives detailed reports of cases that showed unusual aspects and also of those which had a fatal outcome. The reports show that thermocauterization does not always prevent erysipelas. However, the favorable results prove that, if employed correctly, it is a reliable method for the treatment of progressive phlegmons. For the therapy of phlegmons of the tendon sheath cauterization is not advisable, because neither the tendon nor the sheath of the tendon should be burned. But if the phlegmon spreads to the arm, then thermocauterization should be resorted to. Its advantages are the small scar, the elimination of tamponade, of drainage and of frequent changes of dressing, and the rapidity of healing.

Physiologic Principles in Feeding of Patients with Tuberculosis. A. Durig.—p. 1036.

Segmental Neuralgia in Appendicitis.—Czyhlarz reports the case of a young woman who complained of severe pains in the right side. They radiated from the region of the lumbar vertebrae and extended to the region of the appendix. Movement of the right leg did not increase the pain. Pressure on McBurney's point was not painful and Rovsing's sign was likewise negative. Especially striking was the intense pain that was caused when the skin in the region of the appendix was pinched gently, and even superficial stroking of this region was painful. Another peculiar symptom was a point painful to pressure at the right of the first and second lumbar vertebrae, the point corresponding to the exit of the intercostal nerves. Because most of the appendicitis symptoms were absent, it was thought that the pains either were of a functional origin or were symptomatic of a neuralgia similar to the herpes zoster syndrome. The examination on the following day gave the same results. On the third day, however, the symptomatology had changed and now indicated appendicitis. An operation was performed and the patient recovered rapidly. The author asserts that formerly he had observed a similar case. Concerning the development of the peculiar aspects of appendicitis he advances the following theory: During an acute inflammation of the appendix, the pathogenic organism was carried by the lymphatic system to the paravertebral lymph nodes, and here the infection spread to the nerve segment and as a result the symptoms of a segmental neuralgia appeared. When the process in the appendix developed, it became more painful and the local symptoms of appendicitis became more noticeable.

Treatment of Suppurative Bartholinitis. K. Czerwenka.—p. 1067.

Rheumatism as Cause of Static Flatfoot: Rheumatic Flatfoot.—Saxl shows that, if rheumatic inflammations of the musculature, of the tendon sheaths or of the bursae in the lower extremities become chronic, an insufficiency in the function of the foot may be the result and static flatfoot develops. This condition differs from rheumatic flatfoot, which develops from an inflammation of the joints of the foot. To differentiate the two conditions is significant for the therapy. In rheumatic flatfoot the articular rheumatism should be treated first. Rest in bed and the administration of salicyl preparations are recommended. Following the cure of the arthritic process, orthopedic treatment should be instituted if necessary. In cases of static flatfoot the orthopedic treatment is of primary importance.

Etiology and Symptomatology of Aneurysm of Cerebral Vessels.—Steininger describes two cases of rupture of cerebral aneurysm and reports the results of the postmortem examinations. In both cases the aneurysm was caused by a trauma. In the first patient the trauma had occurred six years previously, in the second patient fifteen years previously. In both instances, diseases of the walls of the vessels were absent. The rupture of the aneurysm was sudden in both patients; however, severe headaches, of several months' duration, had preceded the rupture. The two cases demonstrate that cerebral aneurysm may have a traumatic cause. Other more frequent causes of cerebral aneurysm are arteriosclerosis, embolism, hypoplasia of the vessel walls and syphilis. Aneurysms of traumatic origin may exist for long periods without showing symptoms. In the cases reported, the rupture followed excessive use of alcohol and appendectomy, respectively. In discussing the symptomatology of cerebral aneurysm, the author stresses especially those symptoms which aid in the differentiation between tumor of the brain and cerebral aneurysm. If arteriosclerosis, syphilis or embolic processes exist, aneurysm is probable. Many cerebral aneurysms rupture repeatedly and give rise to successive exacerbations. When such repeated exacerbations are noted and when at such times spinal puncture yields bloody fluid, cerebral aneurysm should be thought of.

Social-Psychologic Significance of Spread of Tuberculosis. G. Ichok.—p. 255

Resistance to Tuberculosis.—In experiments on animals it was found that the virulence of tubercle bacilli obtained from persons with tuberculosis was frequently inversely proportional to the severity of the disease. Although strains of tubercle bacilli of decreased virulence were usually found in persons with mild forms of tuberculosis, nevertheless cases were observed in which a fatal outcome was produced by strains of tubercle bacilli of decreased virulence and, conversely, a case of bone tuberculosis of slight severity was observed in which the strain of tubercle bacilli isolated was of great virulence. Lange concludes, therefore, that the clinical course of tuberculosis is influenced less by the virulence of the tubercle bacilli than by the resistance of the patient.

Oxygen Inhalations in Tuberculosis.—On the basis of his observations in thirty-three cases, Oksiusow makes a preliminary report on the treatment of tuberculosis by means of oxygen inhalations. He states that the inhalation of pure oxygen through a respirator increases greatly the assimilation of food by undernourished tuberculous patients who cannot accustom themselves to the large rations used in sanatoriums. An observation period of two or three weeks should precede the oxygen inhalations. This form of treatment is indicated particularly in persons with compensated tuberculous processes who do not gain weight under routine sanatorium treatment. The technic of administration of oxygen inhalations is not complicated. Apparently the inhalations of oxygen cause hypoglycemia and this results in an increased activity of the insular apparatus of the pancreas. Of the thirty-three patients, three (one with hemoptysis and one with endocarditis) did not improve and five had been gaining weight before the treatment was begun. The remaining twenty-five, however, gained 72.87 Kg. in forty-seven days of treatment. It is therefore recommended that oxygen inhalations be tried in a large tuberculosis sanatorium.

Diabetes Insipidus During Pregnancy.—Anselmino and Hoffmann report a case in which diabetes insipidus became manifest in two successive pregnancies and disappeared again during the first days of the puerperium. The diagnosis diabetes insipidus was based on the determination of the sodium chloride content of the blood and of the urine during thirst periods and during water tests. The examinations of the blood and of the urine revealed that this case of diabetes insipidus was of the type that is characterized by hypochloremia and hyperchloruria. On the basis of the Hann-Jacobi theory, according to which diabetes insipidus is due to a disturbance in the equilibrium between the secretions of the anterior lobe of the hypophysis and its posterior lobe (an excessive secretion of the anterior lobe causes diabetes insipidus) the authors reason that in this case the isolated manifestation of the disease during two gravidities may be explained as follows: A syphilitic infection caused a functional deficiency of the posterior lobe. Under ordinary conditions this deficiency was latent. However, during pregnancy the functional capacity of the organ was taxed more and the deficiency became manifest.

Bilirubin Content of Blood During Puerperal Infection.—After calling attention to the significance of the reticulo-endothelial system in the defense against infections, Woskressenski discusses the relation between the reticulo-endothelial cells and the bilirubin content of the blood. In 116 patients with puerperal sepsis the author repeatedly tested the bilirubin content. In those patients who recovered it was found that, although the values were high in the beginning stage of the sepsis, they decreased until the normal content was reached. In cases with a fatal outcome, however, the blood bilirubin increased steadily. In other instances it increased and decreased, corresponding to exacerbation and to improvement in the septic process. The author comes to the conclusion that in cases of puerperal sepsis the bilirubin curve indicates the prognosis.

Symptomatology and Pathogenesis of Exophthalmic Goiter. G C. Bolten. —p. 4002.
*Perforation Symptoms in Appendicitis. R. Finaly.—p. 4019.
Ventriloquism. E. Huizinga.—p. 4023.

Perforation Symptoms in Appendicitis.—Finaly thus sums up: Perforation may occur in appendicitis without high temperature or abnormal pulse frequency in cases in which the closure of the lumen of the appendix and the necrosis of the wall are the result of a mechanical cause and the infection itself is of secondary importance. Under such circumstances, gangrene or perforation may arise before the protecting adhesions have developed. Sudden lessening or cessation of pain is a sign of perforation if that manifestation is followed shortly after by high temperature, increase of defense symptoms and greater pulse frequency. The author warns, however, against regarding the aforementioned manifestation in all cases as a diminution of the process, since the absence of high temperature, almost normal pulse frequency and absence of rigidity in the abdominal muscles may be associated for varying periods with gangrene and perforation. Conservative treatment of appendicitis is contraindicated if the condition of the patient admits an operation, since, if adhesions are present, one cannot wait to see whether they are sufficient to localize the results of a perforation that threatens or has occurred. It will be recalled that the walls of an "infiltrate" are not impermeable for bacteria and toxins. In case of a suspected appendicitis, the physician should not wait until the next day before calling again but should call again in a few hours; for within a short period the true nature of the sickness may be revealed, and by the following day the perforation may be twenty-four hours old and peritonitis may have become generalized.

*Primary Tuberculosis in Adults. M. Arborelius.—p. 115.

Primary Tuberculosis in Adults.—Intracutaneous tuberculin tests (Mantoux) with doses of up to 1 mg. were performed by Arborelius from 1927 to 1929 in 3,288 Swedish soldiers at the start of military service. Negative results were presented mainly by the men from rural communities, fully one third of whom were free from signs of a previous tuberculosis. In about half of those whose cutireaction became positive during service, other symptoms also appeared which agreed with the recognized signs of primary tuberculosis in children. In the more pronounced cases the primary infection was indicated chiefly by fever, greatly accelerated sedimentation reaction, marked tuberculin reaction and roentgenologically demonstrable pulmonary infiltrations in the hilus region. In some cases the picture was that of an acute bronchopneumonic pulmonary process. In three instances, objectively demonstrable symptoms were present before the cutireaction became positive. In the men with a positive reaction to begin with no cases as described were noted, but in several cases tertiary pulmonary tuberculosis appeared. After-examination was made in 218 out of 260 cases of typical primary tuberculosis in soldiers treated from 1923 to 1927. In almost half of the cases, exudative pleuritis had followed within six months. Of the patients examined up to six years after infection, about 15 per cent had tuberculosis and about 8 per cent had died of tuberculosis. While erythema nodosum often accompanied the primary tuberculosis, a connection between the two seems to Arborelius uncertain. Sixty case reports are given, together with a bibliography containing 359 references.

UNIVERSITY IDEALS AND THE FUTURE OF MEDICINE *

SIR WALTER FLETCHER, K.B.E., C.B.,
M.D., D.Sc., LL.D., F.R.S.
Secretary of the Medical Research Council of Great Britain
LONDON, ENGLAND

It is a great privilege for all your guests to be allowed to join with you today in this celebration, and to congratulate you upon the achievement of such notable enterprises within your university and medical school.

Today you praise famous men and the fathers that begat you. Today you give thanks for the generosity of all those later benefactors who have enabled you to approach more closely to your ideals. Today you look back with thankfulness on the road you have traversed so far, and you look forward into the puzzling uncertainties of the future, but with high hopes and well grounded confidence.

You have most generously invited two Englishmen to be honored as your guests here today. I doubt whether you can possibly guess in full the thoughts and emotions that must crowd our minds and hearts as we remember your history and as we now join with you in this commemoration of the past, and this dedication to the needs of the future.

Matthew Arnold said that the University of Pennsylvania should be called "the University of Franklin." It was Benjamin Franklin who truly sowed the acorn that has grown into this great tree—this great university—and it was he who carefully attended to the grafting within it of the school of medicine. He saw to it, moreover, that the hospital which he himself had founded was brought within the sphere of the university as it grew. Because of him, you can rightly claim that your medical school was the first British school of medicine planted beyond the seas; and we, on our part, can hail it as the first school of medicine in America.

I hope it will not be thought out of place for me to speak of Franklin here as one of the greatest British subjects that ever lived. It was because of those ideals of liberty and justice and truth that were inborn in him that he became one of the first and one of the greatest of all American subjects, and we Englishmen have the right to share your pride of possession. May I confess that I, perhaps as you do, like to put Benjamin Franklin in that select list of characters whom I should greatly wish, if I could, to meet in the flesh? How we should enjoy his wisdom and goodness, his keen interest in every created thing, his ripe knowledge of men, women and affairs, his perfect manners, and his dry but refreshing and kindly humor.

You think of him today, and you think also of the long succession of leaders and benefactors who have followed him. John Morgan and William Shippen, Benjamin Rush, Caspar Wistar, Robert Hare, Joseph Leidy and William Pepper—William Pepper here is not a name of an individual but of a whole dynasty; these men give your medical school a noble lineage indeed.

As you think gratefully of the lives and work of these men today you will wish so to plan for the future that the great heritage you have received and possess may be guarded and shaped so as to serve the best intellectual and material interests of the generations to come.

ADJUSTMENT TO ADVANCE OF SCIENCE

We stand now indeed at a time of great anxiety and difficulty in the affairs of medical education and its proper development in relation to other studies. Within the lifetime of by no means the oldest in this room today there has been seen a rapid growth of the medical sciences and the medical arts beyond any parallel in any other period of the world's history. Mankind has advanced further in the development of the powers of medicine in the last sixty years than during the whole of the preceding twenty centuries. The generation just passing has seen the emergence of surgery from the murderous shambles that Lister knew, and from which he saved us, to the modern surgical theater with its refined, intricate and merciful arts. It has seen the rise of the science of bacteriology from its very birth. It has seen developments in various parts of biology and chemistry that have given origin to branches of work, each now claiming to be a separate science, and each showing the strong instinct of the young for setting up in its own house in its own way.

This great and recent expansion of the medical sciences and arts has come so rapidly upon us that little time has been given for the necessary adjustments and adaptations either in our ideas or in our buildings. In every university the machineries of finance and instruction have been strained, and a rapid succession of improvisations has been the only possible mode of growth.

In the field of research the whole body of knowledge has been advancing so fast that the individual workers at their various points on its growing borders are in danger of becoming so far separated one from another in the very course of their advance as to lose the fertility that comes from the easy exchange of idea and method. In the field of education our embarrassments have become acute indeed, both for the teachers and for the taught. The unfortunate students of medicine, who are not yet by any compensation of nature endowed with any greater average ability than their predecessors, are now nevertheless obliged when equally young and within the same period of time to acquire a much larger body of detailed knowledge;

---

* Read at a convocation held in celebration of recent medical progress at the University of Pennsylvania, Philadelphia, Oct. 10, 1930.

indeed, they must learn in several subjects not far from threefold that which was necessary only a generation ago. In every medical school the teachers feel acutely that circumstances are becoming almost too strong for them and that the medical student is now in danger of receiving not an education worthy of the name but only course after course of hasty and crammed instruction.

The efforts made in the universities of the United States to meet the needs of this time of almost fevered growth and transformation have been most remarkable, and they have been studied with interest and admiration by every other civilized country. You have had some great advantages. You have enjoyed great wealth, and this has been made freely available by private benefactors for enlightened public purposes. You have the fine tradition, sadly lacking still in many parts of Europe, that it is an honorable obligation for the sons of any university to repay some part of their debt of her by helping, according to their means, the expansion of her freedom and power. You have not been afraid to make bold experiments, to tear down buildings not fully efficient, and to adopt the best of what you can devise here or find elsewhere. You have been able by your variety of institutions to proceed, if we view the country as a whole, by the method of experiment, and all other countries have been able to gain by the study of the results, whether found in your educational methods or in your material installations.

Here in Pennsylvania you have had the advantage and the stimulus of possessing the senior of all the medical schools of the new world. Over a hundred years ago you had built more accommodation for your medical school than had been dreamed of then at either Oxford or Cambridge. Over fifty years ago you had taken the daring and original step of building a hospital as an integral part of the medical school within the university, and that is an advance that has not yet been emulated by any university within Great Britain, greatly as it is to be desired. You built a university laboratory of hygiene long before any other existed in Great Britain. You have not allowed, moreover, this early start and your seniority to impede you by any viscosity of conservative tradition. You have torn down and rebuilded, again and again. You now have a constellation of magnificent and well planned buildings, providing for research and education over all the great present fields of medicine. Your visitors here have cast admiring, though sometimes envying, eyes on these results of the planning by devoted and skilful men, and by the generosity of your benefactors.

Benjamin Franklin in his day spoke of the scanty resources to be found in Pennsylvania "in a hundred leagues," as he said "of our vast forests" as compared with those to be found in every part of England, England which he described as "that pretty island which is but like a stepping stone in a brook, scarce enough of it above water to keep one's shoes dry." Those of us who come, as I do, from that "pretty island" may well wonder what Franklin would have thought, and how greatly he would have rejoiced, if he could see the great buildings that now adorn so many acres of Pennsylvanian ground, the outward expression of the intellectual resources you celebrate today.

No doubt you have had your own anxieties here, as we have had in England, during these years of rapid expansion and building—anxieties lest particular endowments and the satisfaction of today's urgent need by buildings of particular kinds should bring, so to speak, a premature static crystallization in stone of the dynamic growth of rapidly advancing sciences. You may have anxieties again lest the funds that have been provided should be absorbed unduly by bricks and mortar, and not adequately invested in the proper maintenance and reward of the scientific workers, without whose ability and labors the buildings would remain an empty shell. All these anxieties yield problems that are to be solved only by trained knowledge and by a sensitive imagination; but they are problems of which the solution as it is worked out must affect for good or ill the development, health and happiness of all the generations to come.

EXTENSION OF MEDICAL SERVICE

William Penn said that the wisest man was he who could see farthest into the future. It would be a very wise man who could forsee in any detail the paths along which medicine is to advance in the days to come, or outline the new territories it will occupy. But we can draw at least some general conclusions from the intricate story of the recent rapid developments. We have to think of these under two main heads, one concerned with the growing extensiveness of medicine in its practical application, the other concerned with the intensive development of the fundamental sciences that serve it.

The very word "medicine" has for all of us, at first sound, and certainly for all laymen, a disagreeably narrow meaning. We think of the drug or mixture prescribed by the doctor in our illness. Doctors' potions indeed, by a curious mischance we must not now examine, have always unfairly attracted to themselves words far too dignified and too general for such narrow uses, whether "medicine" from the Latin, or "physic" from the Greek. Medicine in its proper sense has a far wider and nobler application. It includes all the sciences and all the high arts that the practicing physician or surgeon brings to serve his fellow man in disease or accident. But the true realm of medicine has already extended, and is still extending, far beyond this; more and more, as our knowledge grows, it is coming to have its domination in almost every activity and interest of human life. For one thing, it has become more and more addressed to the arts that are preventive rather than curative. In this audience and in this country I need not refer in any detail to the great and familiar triumphs of modern preventive medicine, whether in the fields of sanitation and hygiene or in the fight against specific tropical diseases. More and more, again, has medicine been brought to meet the practical needs of our modern industrial life and to guard the health, comfort and usefulness of the workers in factory, workshop and mine. You may well be proud in this country of the part your men have played in the development of tropical hygiene and of industrial medicine; brilliant instances of their achievements that have made life easier for the worker or more possible in the tropics will be in the minds of everyone here.

This modern extension of the fields of medical service has indeed been so rapid and far reaching that it is becoming almost difficult to find any department of man's daily business which it does not vitally affect. It may interest you to know that the British government has had recent occasion to find a formula for delimiting the field of medicine, and that which has been adopted by it is the following:

> Medical research deals by no means only with the cure of disease. It deals with the proper development and right use

of the human body in all conditions of activity and environment, as well as with its protection from disease and accident, and its repair.

You will see that in the vast territory here marked out there lies the whole volume of human life in all its daily business to and fro on the earth between the cradle and the grave.

With every year that passes now, moreover, the points of contact between the functions of humanity and what we have still perforce to call "medicine" are fast multiplying. We are bound to expect that the recent growth of medical territory is but little as compared with what our children will see in the coming years. I need point in illustration of this only to two, among the many, new territories, the new continents of knowledge, just opening before us. We are now only in the first dawn of our knowledge of the laws of nutrition, and of the ways in which the state of the body is affected by changes, often almost incredibly minute, in the exact quality of the food supplied to it. Even the successes already won in this field in the prevention of scurvy, of beriberi, of rickets and of deficiencies in teeth only show us dimly the immense possibilities that lie before us here of gaining new powers of controlling health and of evading disease.

We are now only at the dawn, too, of our knowledge of mental processes, and of the intricate links between states of the body and states of the mind. How dare we set any bounds to the empire that must open to us as growing knowledge becomes translated into new powers in education, new powers of finding by scientific method the choice by the individual of the work and career most likely to make him most useful and happy; and new powers again of maintaining or restoring mental health?

These illustrations I give must be so familiar already to you that I shall seem to be guilty of platitude when I say that the physician of the future must find his work to become more and more concerned with those two fields of nutritional science and mental science—with the healthy body and the healthy mind. May I, nevertheless, and in digression, point out to you here that though the practitioner has these two new worlds opening to him in which so great a part of his effective future work must come to lie, yet so rapid has been the advance of knowledge as compared with the motility of human institutions that even now, in Great Britain at least, the medical student receives at no point in his course of study any well based and organized instruction either in the field of nutrition or in that of mental functions. In those fundamental subjects he has to depend at present on little that deserves any better description than that of occasional gossip, while the resulting loss to the community at large is immeasurable.

DEVELOPMENT OF FUNDAMENTAL SCIENCES

While medicine has thus been extending its kingdom and multiplying the fields in which it has practical service to give to mankind, at the same time another development has been marking this age, an intensive development in which medicine has been bringing more fully into her service and discipline the fundamental sciences on which all the arts of medicine depend. The central science of medicine is physiology, the study of the functions of living matter and of the organized body. As knowledge grows the physiologist is taken deeper and deeper into the problems which on the one hand call for the technical methods of the chemist, and, on the other, need the methods of the physicist. In science it is not differences in kinds of knowledge that demand new buildings, but differences in kinds of technical method and apparatus. What was first called physiologic chemistry has now set up in her own chambers as biochemistry. Only thirty years ago there was no professorial chair of biochemistry in Great Britain; now chairs and separate buildings for it are to be found in almost every university. Here similar developments have come with ever greater rapidity and completeness.

The development of physics in relation to medicine seems likely to follow a more complex path. The direct application of physics in aid of the physician and surgeon by means of x-ray photography for diagnosis, and the use of irradiations of divers kinds for curative treatment, have called already for extensive equipments and for specially trained men to use and apply them. But physics is beginning to have a more primary and intimate part to play in biology and medicine than this. I need only mention the advancing study of colloidal states in relation to the processes of the living cell and the functions of the body; or, again, the analysis of the action of light radiations in producing from a given molecule, whether outside the body or on its surface, the still unknown but vital constituent of food—the so-called vitamin D.

Or I might point to the fascinating study by refined optical and other physical methods of those mysterious, elusive and invisible bodies, the so-called viruses. These are the agents of many of the most distressing, most fatal, and most expensive of diseases among men, live stock, and crops; they stand in size between the smallest known unit of living matter and the largest inanimate molecule; and they have almost incredible powers of rapid self-multiplication. Our hope of mastery over them appears to lie largely in the improved application to their study of refined optical and other physical methods.

You have been able to establish here already an institute for medical physics, providing for the development of physical methods useful in practical medicine as well as for the more fundamental researches in what may well be called biophysics. This significant venture will be watched from far and near with great interest and hope. You have happily so planned your scheme as to allow growth of the subject to follow its natural lines, so hard for us now to foresee in detail, and to follow in organic relation on the one side to the arts of medicine, and on the other to the primary sciences of living matter.

I would ask you here to note a feature of great interest in this story of the rise of biochemistry and biophysics—a feature of it destined, I think, to have a fixed importance in the history of medicine. Biochemistry was born the daughter of physiology. Medicine, indeed, has always been the mother of sciences. At the beginning, the trained organic chemist was inclined to think slightingly of his new cousin, the biochemist, who dealt under so great difficulties with material inherently evanescent, and, from the chemist's standpoint, so uncleanly and confusing. Almost everywhere a great change has come in this respect. The pure chemist has come to see that in the living cell are proceeding at great rate, and at low temperatures, transformations that he could have performed himself in the laboratory only at the cost of relatively immense energy and violence. Patient study of the chemical conditions and processes of the cell has already revealed truths of created wonder that otherwise would have lain beyond chemical knowledge. The chemist is now entering into biochemistry not only to bring his long acquired skill to aid medicine but in order himself to make additions to chemical knowledge as such. The time will not be long deferred, as we must believe, before the physicist in like measure will increasingly come not merely to cooperate with those who are advancing medicine, but come so as to find in the world of living matter his own absorbing interest and his own opportunity for gaining new truth.

PLACE OF THE SCHOOL OF MEDICINE

What broad lessons of university policy are we to draw from considerations like these? I have endeavored on a broad view to sketch the double form of growth now manifest in medical development. I have spoken of the extension of its kingdom in every part of human life. I have spoken of its increasingly intensive use of the technical methods belonging to almost every branch of fundamental science. If we find these views of it to be true, what guidance do we gain for the future? To that I think the answer, again on broad lines, is both clear and simple. It is that the school of medicine should be, and should continue always to be, as here it has always been, an integral and organic part of the university. I would not play with words here but think in terms of realities. It is easy to retain a school of medicine nominally and formally within a university, and yet to segregate it as a self-sufficing technological institute. When I speak of a medical school as properly within the university, I mean that it would be embedded within the organic structure of the university, both as to its functional relations and as to its geographic position. It should bear its intimate share in the common intellectual and moral ideals of the complete university body. I would justify that claim on all grounds, whether those of the expediencies of today or those of the ideals that endure through all ages.

Let us take the lowest ground first, the ground of expediency; a school of medicine which is an independent unit, or which is divorced organically from its university in function or in geographic distance, can hardly hope to be more than a school for producing well trained practitioners; it can hardly hope to attract any recruits to the service of medicine other than those who, from the beginning, seek to fit themselves for professional practice. The practice of medicine offers indeed one of the noblest of all callings, and you will not think that I do not hold it in the highest honor. "The skill of the physician shall lift up his head; and in the sight of great men he shall be in admiration." The fields, however, in which medicine has to give service to human life have extended already, as we have seen, and have still to extend, far indeed beyond those of the professional practice of curative medicine. Divorcing a school of medicine from the free current of university life must have a double peril. It must endanger the width of outlook of those who are being trained to enter a profession in which, of all professions indeed, a primary qualification for success is a sympathetic understanding of the ways and thoughts of other human beings. At the same time the isolated medical school is in danger of sacrificing to the visible needs of the practitioner of today those wider destinies which, as we have seen, are now opening so rapidly to medicine over so many and diverse fields of human activity.

If dangers come, as I submit, from a narrowness of outlook that may impede the free development of the service medicine has to give in the future progress of mankind, other dangers again will come in another way and in high degree from any isolation that tends to divorce medical studies from the system of disinterested scientific studies within the university. It is vital to medicine to maintain her increasingly intensive use of the primary sciences. Any secession from the unity of knowledge brought about by the undue segregation of medical studies must pay some penalty in weakness and sterilization. This is no empty phrase. It is a truth which practical experience, both positive and negative, has established again and again in many places. It is a truth of which the working out may come in many different forms of reality.

It may be enough now to point only to the damage done to the recruitment of able minds to the service of medicine, if medicine stands apart as a purely professional study. The history of medicine bears name after name of illustrious men who, with no thought of professional practice, have come into her service, attracted and recruited by some chance contact with her claims and her charms. At no time has this been more evident than in the past generation, and it has been evident just in proportion as university organization has facilitated the best freedom of exchange in men and in ideas among the several sciences and faculties. If the negative experience be sought, it may be found in the relative sterility that has marked those departments of medicine that have been so organized or so placed as to receive only the narrowed stream of students vowed from the beginning to one avenue only of medical service.

These, in outline only, are the arguments based on grounds of practical expediency alone, and they are weighty enough. But there are higher considerations to be taken into mind. Medicine must lose immeasurably if her studies are withdrawn from the atmosphere of university life and the impact of university ideals. The essence of a university lies in that bond of sympathy in a common pursuit which unites all the workers in all her faculties; a sympathy that brings a mutual understanding of the general relations of all branches of knowledge, of their limitations and of their difficulties. It is through this universality of sympathy, and only by making the whole field of knowledge her kingdom, that the university can place her true mark on her sons. It is the simplicity of this single purpose that marks the university, and not the complexity of her studies. The common spirit that unites all her workers is the furtherance of knowledge for its own sake, and the dedication of it to the highest purpose. Can medicine afford to lose her birthright in this community of work and aim? Can any university suffer without grievous loss the abstraction of that reinforcement to her influence that comes from those high intellectual and moral ideals that should be the life blood of medicine?

Some recent events may make us reflect here that the true ideals of a university unite no less within a common bond the universities of all the nations. With this is bound up the instinctive and habitual recognition by every worker of the debt that he owes to his predecessor and contemporaries in all parts of the realm of learning, and of the gain that comes to his own progress from the rapid and untrammeled interchange of knowledge and ideas as they are won by free inquiry. It should rightly be unthinkable that any university giving faith to these ideals should engage in claiming monopoly rights or making financial gain in the practical uses of any piece of knowledge, and least of all that it should exercise any ostensibly legal rights of monopoly so as to cause restrictions of free inquiry elsewhere. Every great step in knowledge won within a given university is based on all the long labors in other universities that gave the earlier steps. To take monopoly value from the accidental chances that link new knowledge with possibilities of commercial profit is to betray the essence of the university spirit. It seems also to be as inexpedient on a long view as it is improper. Rich men have most generously aided the universities of Canada and the United States. Will they be so willing to find help for a university that cares to make large profit by taking for itself the ripe fruit that falls from the tree planted and grown by workers elsewhere throughout the world? If financial gain comes to a university in that way there must arise, moreover, the grave dangers of a vicious indirect influence affecting the outlook of all the individual workers within it. It will be difficult for them not to feel that the university will be more inclined to reward by pay or promotion him who makes some addition to knowledge of an immediately profitable kind rather than him who works for the sake of knowledge itself. Nothing could be more disastrous than this, as we know, to the advancement of knowledge itself, and in the long run, indeed, to the material gains of the world. Only those who know the intimate realities of research work can realize how much the world will lose if the now open door of the medical laboratories becomes jealously closed.

PROGRESS THROUGH KNOWLEDGE FOLLOWED FOR ITS OWN SAKE

The servants of medicine have the challenge always before them of a direct objective, near for some, more remote for others, but always in sight—that of lessening pain, and of bringing to their full development the mind, body and estate of mankind. Little wonder if in their eagerness to press on to their goal they feel impatience of any but the paths that seem so direct and obvious. But here the lessons of science are the same as the lessons of high morality. The work of mercy can be effective only so far as knowledge guides it; and new knowledge comes, as long experience has taught, to him most fully who seeks it for its own sake first. Charity and loving kindness to our neighbor is a high commandment indeed but it was called the second commandment. The first and great commandment is to give with the whole heart and the whole mind our worship to truth for its own sake and for the sake of the beauty that it reveals.

In the air of a true university, these fundamental lessons are learned as a part of everyday reality. I venture to say that these ideals of the university spirit have been your inspiration here from the beginning, and that your great school of medicine, fostered for more than a century and a half as an integral part of the university and as one of her most favored children, has grown to her present stature under their guiding influence. Those of us who are honored by being with you here today have rejoiced in your recent accessions of strength and opportunity. We wish you Godspeed from our hearts in the further progress of your university medical school. Its work in the past and in the present may surely encourage you in a high confidence that it will now, in renewed and growing strength, go forward to service beyond any present calculation in the advancement of knowledge, the conquest of pain, and the elevation of mankind.

15 Holland Street, Kensington, W. 8.

THE PHYSICAL REASONABLENESS OF LIFE [*]

A. V. HILL, M.A., Sc.D., O.B.E., F.R.S., LL.D.
Foulerton Research Professor of the Royal Society
LONDON, ENGLAND

When I had the honor to propose my friend Professor Bronk as a member of the British Physiological Society I cited, as one of his qualifications, that he had written papers on astrophysics. This—as you may imagine—was not meant entirely seriously; nor will you charge me with supposing that a knowledge of astrophysics is, in itself, of use in physiology. There may even have been a gentle note of provocation in what I did; I may have hoped to draw an echo of protest from Prof. J. S. Haldane, who contrives—not quite seriously—to object to the use of what he is pleased to call mathematics in physiology. The most serious things, however, are often said and done with a smile. At the back of Haldane's mind, disguised in his laughing insults to quadratic equations and his jesting horror of electrical apparatus, is perhaps the strongest motive of his intellectual, one might almost say of his spiritual, life, the faith that in the living organism regarded as a whole there is something which is not simply present-day physics, the insistence that the conception of an organism is as fundamental to biology as those of electricity, space and time are to physics. I did not succeed in provoking him when I proposed Professor Bronk for membership; which is perhaps as well, for, in spite of our mutual recriminations on the subject of what he calls "mathematics," I am proud to reckon myself, in philosophical matters at least (and when I can understand him) to some degree as his disciple; indeed, if he is not abusing me for being a mechanist he is blaming me for being a vitalist—which apparently is as bad though the average is right.

I am not intending to tell you today—you have heard it often enough and it is not true—that the phenomena of life could be explained, at least by some one clever enough, in terms of the physics and chemistry of the present time. Whether the future physics and the future chemistry will suffice I will not guess; when the events of physics have become indeterminate, and the physicists, poets and mystics; when chemistry has become physics, and the chemists have become physiologists; then, indeed, the situation may be different. Until that day I shall continue—with Haldane—to insist that in the organism regarded as a whole we have a phenomenon of a different kind, one whose unity and fundamental nature are as essential as any of the concepts of physics. Why I wanted to provoke Haldane in respect to Bronk's wild oats is that I hold, and he in theory does not, though in practice he does, that the most fundamental way of investigating that organism is the way provided by physics; and that to employ physics properly biology needs, not people who have read it up the day before in an encyclopedia, not people even who might get a good second class degree in it if they tried, but the proper article. It is because I know that Bronk is the proper article and feel that his new department, the Johnson Foundation for Medical Physics, represents a great and fundamental step forward in biology and medicine, not only in Philadelphia but in America, that I have had the impudence to come here today to address you.

---

[*] Read at a convocation held in celebration of recent medical progress at the University of *Pennsylvania, Philadelphia*, Oct. 10, 1930.

SCOPE OF PHYSICAL METHODS

Physical methods alone—and those of the best—are adequate to investigate the physical phenomena of life. Some people will say that in describing these phenomena as physical we are missing their essential biologic import, we are drawing a red herring across the trail. I do not believe we are. Convinced as I am that no physicist, however bold or learned, with the aid of all his wave mechanics, his quantum theory and his relativity, can hope to describe the whole of our behavior here this afternoon as due to the properties of proteins and electrons, certain as I feel that Laplace was wrong in believing that, given the motion of all the particles of matter at any moment, a sufficient intelligence could predict all future history, nevertheless, I am quite sure that when a living organism shows phenomena of any kind which we can appreciate by our senses, those phenomena and their nature can best be investigated by physical means. And I am equally sure that such investigation will be very profitable for the future of biology, and in the end—through medicine—for the welfare of mankind.

There is really no contradiction here. If you take any of the machines conceived and made by man you will find that their detailed characteristics are essentially of a physical and chemical nature; the properties of steel and brass, of oil and water, of electricity and magnetism, of lead and acid, of copper wires and insulating tape, may all be investigated by physical and chemical means—he would be a poor engineer who held otherwise. Yet a man-made machine is essentially a human phenomenon: it was designed for a purpose, it fits man's biologic needs, it has adaptability or flexibility as we say, within certain limits it continues to function in spite of changes in its environment. In a minor way a medicine is an organism, part of the greater organism of human society.

There is nothing biologic about the properties of copper, steel, carbon, rubber and shellac; yet to deny the rôle which an electric motor or a dynamo may play in human affairs would be idle and absurd. There is clearly an essential difference between a complex electrical installation, regarded as a whole, and the materials of which it was built up. Design and purpose are apparent in the former, adaptability and coordinated response, properties inherent in the human minds which designed and built it, but not at all in the properties of matter as such. The engineer, however, who attempted to study, or to design, machinery without a very complete knowledge of those properties, would land himself in insoluble perplexities; his machines would never work.

The driver of an automobile may be, he sometimes is, acquainted with the purpose of the several parts of his machine. To construct, or to repair, however, requires very much more knowledge than merely to drive; and the physical properties of the materials are, though it may not always be apparent to the layman, the basis of the whole design. Had aluminum had all the properties of steel, except its density, copper ten times its actual conductivity, had air consisted of 79 per cent oxygen and 21 per cent nitrogen instead of vice versa, had the intensity of gravitation been ten times greater or less, what extreme differences there would have been in engineering construction and design! So it is in biology: the properties of matter are its foundation; the detailed phenomena which appear in the living organism, of which we are aware through our senses, are physical or chemical in nature and must have a physical or chemical basis. It is inconceivable, indeed, that if phenomena involving heat, light, sound or electricity are witnessed in a living cell these should not be found to depend on other factors of a physical kind. Unless we believe in magic, and as scientists presumably we do not, we must hold it as inconceivable that any physical effect whatever should not be linked with some preceding physical cause.

To that extent the physiologist must be a complete and absolute mechanist—he must admit no judgment except that of experiment, no immediate cause of any individual phenomenon except the material physical one preceding it. His problems are very difficult and complex, they may require more knowledge, more intelligence, more skill for their elucidation than at present he possesses. No matter, it is futile, not to say impudent, to assume that because his limited powers, now and here, cannot solve them, therefore they are insoluble and some form of magic or miracle must be invoked.

The title of this address was chosen with care. Convinced as I am that the whole intelligence of man, and not that particular corner of it which is concerned with exact and quantitative reasoning, is adequate to grasp the full significance of life in the biologic sense, I would much rather claim too little than too much. I do want, however, to insist that life is physically reasonable, in the sense that its detailed characteristics can best be studied by exact and quantitative experimental methods. For some years I was responsible for teaching physiology to medical students; and I frequently asked myself—or they asked me—what was the good of teaching them this and that? Why should they learn about frog's muscles and nerves, about the electrical change of the heart, about membrane potentials, and hydrogen ion concentrations? Why should they be forced to study mechanics and to pass an examination in physics? Most of them would have no use for these things in after life; a little more personal skill in handling patients might serve them and the patients better. One answer, I think, is this: they must be made to feel what I have called the physical reasonableness of life. A belief in magic is still widespread; who among us is quite free from it? And we do not want to be quite free. The common folk are all too ready to trust in the magical power of medicine or of treatment and to think of doctors as wizards or magicians. It is fatally easy to believe what it is convenient to believe, and the education of a medical man should lead him to the instinctive and confident view that magic has no place in medicine, that it is professionally dishonorable to believe, or to suggest, explanations of phenomena or methods of treatment which are physically unreasonable. To give physics, and physical methods competently and critically used, a high place in your medical curriculum is to set men's faces definitely in the right direction, and your influence against the spread of magic and fraud.

THE JOHNSON FOUNDATION FOR MEDICAL PHYSICS

We are celebrating among other things today the noble gift of Mr. Eldridge R. Johnson, from which has arisen, under the far-sighted inspiration of his friend Dr. Alfred Stengel, the Johnson Foundation for Medical Physics. It is fitting that in the oldest medical school of this continent, in the city of Franklin, one of your greatest experimental philosophers, there should be this opportunity given to see how far modern experimental philosophy can aid in the understanding of life and disease in the alleviation of human suffering. To show how this may happen I cannot do better than refer to the booklet which has been prepared to celebrate this occasion.

> As research thus yields a more quantitative understanding of vital processes in terms of these physical principles, it becomes increasingly possible to approach clinical problems from this point of view. It is one of the aims of the Foundation, therefore, to interpret pathological and normal biological systems in terms of physics; to study the effect of physical agencies such as light, heat, sound and electricity as normal factors and therapeutic measures; and to make the results of such investigations readily available for clinical use. As a consequence of such developments modern clinical practice and medical research are constantly meeting difficulties which can only be solved by men trained in the physical sciences. A second function of the Foundation therefore is to make available to the medical school an organization capable of solving specific problems that face the clinician either in the ward or in his research. This cooperative research makes possible a more adequate physical approach to many medical investigations and keeps the staff of the Foundation in close touch with practical problems of the clinic. A related type of activity is the development of new methods and apparatus for medical treatment, diagnosis and research. . . . A modern well equipped shop and instrument-design room are located in the Foundation laboratory and are under the direction of a graduate mechanical engineer who is in charge of design and construction of apparatus. These facilities are available to all departments of the Medical School. The increasing use of physical agents in therapeutics, the increased possibility of approaching medical and biological problems from the physical viewpoint and the usefulness of biophysical methods in the solution of medical research problems indicate the need for better training in this field. Members of the staff are available for lectures on established courses on such phases as are of a physical nature. Graduate work is offered leading to the degree of Doctor of Philosophy in cooperation with other departments of the Medical School and the Department of Physics. And one research fellowship is offered each year to a medical graduate of at least one year's standing, which offers full time for research on a problem of clinical interest that is of a physical nature. Through these instructional activities the Foundation hopes to increase the supply of workers in this field and to improve the capacity of the medical profession to utilize physical methods and principles. Thus established to carry out these several purposes, the Johnson Foundation promises to render a unique service to medicine and to lead the way in a rapidly developing field.

I could not summarize better than by these extracts the motives of those who are attempting all over the world, and particularly here, to apply the methods and ideas of physical science to biology and medicine; and I am completely confident that so long as Bronk is skipper of the ship, the faith of those who planned and endowed this new adventure will be rewarded by rich and wholesome cargoes.

COMRADESHIP IN SCIENCE

For those who sail and adventure—as Bronk and his crew will do—in the seas which lie between one region of science and another, life is not dull; strange, unexpected and valuable things turn up as the result of contact between different kinds of culture and different types of mind. What does not physics owe to mathematics, chemistry to physics, physiology to both of them and to zoology, anatomy and medicine? One of the happiest comradeships in science was that of Bayliss and Starling, the one essentially a physicist in outlook, the other a biologist. It is said by those who ought to know that few Englishmen of the present day have served clinical medicine so well as Sir Thomas Lewis the physiologist; certain it is that English physiology owes a great debt to the discoveries of Sir Thomas Lewis the clinician. Lewis's discoveries in cardiology were made possible by Einthoven the physicist; Einthoven the physiologist with that charming modesty which made us love him so much retorted that without Lewis's discoveries nobody would have thought of giving him the Nobel Prize for Medicine—which maybe was true. Hopkins played a leading part in the discovery of vitamins; I wonder how far he would have gone on that path had he not been chemist enough to discover tryptophan. The beautiful work of Erlanger and Gasser and their colleagues on action potential waves in nerve was possible largely because Gasser, alleged to be a pharmacologist, is by instinct and taste an electrical engineer; the no less beautiful work of Adrian on the physical basis of sensation was made possible, as Adrian himself confesses, by the invention of the amplifying valve. Kieth Lucas, one of the greatest of English physiologists, was a first-rate mechanic and instrument designer; his father's connection with the Telegraph Construction and Maintenance Company, and his voyages in the company's cable-laying ships, had early given his mind an instructive bias to electrical methods. Helmholtz's studies in the physiology of hearing and vision were possible only because of his mathematical and physical knowledge. One of the happiest men in the world is Sir William B. Hardy, zoologist, colloid chemist, physiologist, physicist, engineer, now director of a laboratory in Cambridge for studying the problems of refrigeration, all his life a sailor and adventurer in unknown seas. I need not weary you by a longer recitation of names; you know many such men in your midst; and they are, like Hardy, happy men, who could not dream of giving up their adventures on the high seas between the different sciences for any stay-at-home job.

The increasing speed of scientific development, and the increasing specialization which results, make it the more necessary that a certain number of research workers should be trained and interested in two sciences at least and working in the field between them; otherwise great and important possibilities may be missed. It is impossible for a single man to cover the whole field of science; it is becoming impossible to be acquainted with the whole of any single branch of it. If there is to be coordination and not confusion there must be continual overlap; the zoologist can make contact with the chemist if both know something of physiology; the clinician with the electrical engineer if both know something of physics; the bacteriologist with the biochemist if both know something of zoology. It is apparently too much to expect that professional physicists or mathematicians—except in rare cases—should know anything of biology; unfortunately it is possible to study physics and mathematics at school and university, to the exclusion of almost everything else, certainly of that major half of natural knowledge which is contained in biologic science. This may produce excellent physicists and mathematicians, but it leads to a singularly one-sided, one might almost say an uneducated, view of the real world; and, judging from the number of distinguished physicists who are prepared to dally with spooks and spiritualism, to a very unsophisticated and uncritical outlook on anything but their special subject. Be that, however, as it may, the fact remains that in general we biologists, and you medical men, can expect very little direct help from the majority of physicists and mathematicians; it is necessary that some of us should study these matters for ourselves.

This is no small task—the discipline necessary for an adequate and critical use of physical methods and ideas cannot properly be given in the crowded years of a medical course. It is necessary that a certain number of properly trained physicists should be attracted to biology and induced to turn their attention to its problems. We want men with disciplined and critical but also with adventurous minds to guide us in the seas which separate biology from physics; and rich are the prizes they will help to bring home to port.

VARIOUS APPLICATIONS OF PHYSICS

Let us return to the title, the "physical reasonableness of life." Consider the biologic effects of radium. Most of us have heard of the great success of radium, properly used, in treating certain forms of cancer, particularly cancer of the breast; we all know, however, that the high hopes with which its general use in cancer has sometimes been proclaimed have not been entirely fulfilled. There is no doubt at all of the effect of radium on living cells; but, strange to say, the mechanism of the effect is still uncertain. There is presumably nothing magical about it. X-rays act in a similar manner; both may work by releasing high-speed electrons in the interior of the cell. Why, however, and in what way should a normal cell be affected by a high-speed electron? It is not impious to ask, any more than to inquire why the human body needs water after exercise on a hot day. There is presumably an answer. How many such electrons are required per cell; within what range—if any—must their velocity lie; what part of the cell must the projectile hit; which cells are therefore the more susceptible; why are certain cancer cells apparently more readily damaged and destroyed by the bombardment than are normal cells, or may not the effects be due to stimulating the good cells rather than to injuring the bad ones? Such questions are obvious enough—and if we believe in the physical reasonableness of life they must have answers which presumably will not be too difficult for human beings to understand.

Consider the common hen's egg. The yolk represents a single enormous living cell, surrounded by a very delicate extensible membrane; it is suspended in the white; any physical chemist, and most biologists, would have guessed that yolk and white would have the same osmotic pressure. Not a bit of it! The osmotic pressure of the yolk is one-third greater than that of the white and remains so for many days, even in the complete absence of oxygen, so long indeed as the egg is alive. The phenomenon is obvious enough; there is no magic about it: it is surely not impious to inquire about it; no purely biologic reasoning can throw light on the matter, which may prove to be very important; if we believe that life is physically reasonable we must use physical tools for its elucidation.

The little red fiddler crab, *Portunus depurator,* always lives in deep sea water. He has no mechanism to withstand a dilution of his environment. Put into diluted sea water he rapidly changes the concentration of his body fluids, presumably by transfer through his gills, until in four or five hours he has come into equilibrium with his new surroundings. In 50 per cent sea water he dies; in 75 per cent he may live, apparently indefinitely. The shore crab, *Carcenus maenae,* on the other hand, must be ready to meet diluted sea water in estuaries, or concentrated sea water in pools. He may tolerate 25 per cent sea water for days, slowly diluting his body fluids until they reach an apparently steady value isotonic with about 60 per cent sea water. His gills presumably are permeable to the salts of sea water but are able also to resist their passage; they have very different properties from those of the fiddler crab; they are,—though initially permeable—able finally to tolerate a considerable difference of concentration on their two sides, an admirable property, essential to the crab's existence, very important presumably in some of our own cells, e. g., in the kidneys and alimentary canal, but depending on factors quite unknown. To attribute the phenomenon to some vital action of the cells is merely to put it in a certain category, not to explain it. Is it analogous to the case of the hen's egg, has it anything to do with edema or secretion? If so, the further investigation of such things by physical and chemical means may provide us with a harvest of useful information.

Few subjects are more important than physical pain. Its nature has been debated since man began to ask questions. Philosophies and religions have taken cognizance of it; few men can face it with equanimity; a disregard of it has been reckoned one of the greatest virtues. Who would have thought that the study of electrical changes in living tissues on the one hand, and of the conduction of electricity through gases on the other, would have led to the beginning of understanding at least of its physical nature and accompaniments? Yet such is indeed the case. With the aid of amplifying valves, and the beautiful physiologic technic which Adrian has invented, painful impulses in single nerve fibers can be seen on a screen, or heard in a loud speaker, intensities of pain can be measured, the difference between pain and mere sensation made clear. The philosopher may say, But this is not pain, only an accompaniment of it; maybe; but at least if the impulses are stopped the pain will end. If we can understand the nature of these impulses and the manner in which they originate, if the quantitative nature of the physical basis of all sensation can be properly described, then indeed a new field of research will be opened in neurology and a new era in medicine.

It is now beyond dispute that the principle of the conservation of energy applies just as rigidly to living cells as to the rest of the world. By Prof. Graham Lusk and his associates in New York, accompanying and following a long succession of workers in all parts of the world, this principle has been made the foundation of the science of nutrition. Vitamins indeed and salts and other things there must be, but a certain minimum of calories is essential. The animal machine, just like the steam engine, must be fed with combustible fuel to supply it with the energy it needs. In this respect at least nobody believes in magic any longer; the living cell can no more produce energy than it can produce matter out of nothing. This particular application of physics is obvious and complete; and without it a large part of the sciences of life would be unintelligible. Let us remember it when we consider the importance of biophysics.

THE GREATER ROMANCE

In a public speech it is wise to attempt to move the hearts, as well as to interest the minds, of one's audience. It would be very difficult, however, indeed well nigh impossible, to move men's hearts much by reference to the achievements and the future usefulness of a branch of science. I have urged that we must not believe in magic—that a training in physics and biology, an acquaintance with the facts of medicine and neurology, will prevent an unreasoning belief in spooks and spiritualism and miracles; a most depressing conclusion, for it is romance and magic and miracles which really move men's hearts, however hard they apparently be!

> "Romance is dead," as Kipling said, "and all unseen
> Romance brought up the 9:15."

The greater romance remains. Did we believe in the stories of spiritualism, in the alleged antics of the spirits of those who have passed on, we should be forced to conclude that the next world is filled with gibbering idiots. Did we hold with many common superstitions and accept many common forms of magic, we should have to conclude that the Ruler of the World ought really to be shut up in a madhouse. The world is not less beautiful if bits of it become intelligible; a tract of country is not less romantic if we carry a map; the sky is not less blue if we know that the blueness is due to the scattering of light by particles or molecules far up; there is no less pleasure in achievement if we use good tools than if we use bad ones. In scientific research we work and work, sometimes for months and years, in digging a tunnel with no apparent results; then suddenly comes the supreme joy of life—daylight begins to glimmer at the end, and in a few minutes we see that nature, after all, has not played us false. To one who works honestly and accurately, these moments are sure to come. And in using physical methods the joy is so much the greater because the achievement is more sure. Not only do we find the promised land, but often its details agree with surprising accuracy with the quantitative forecasts that have been made about it.

It is no use, therefore, to tell a scientist that romance is dead, or a physiologist that physiologic problems are insoluble; the emotions he has experienced in finding new worlds will effectively prevent him from believing you. No joy can be greater than to find convincing evidence for one's faith that nature is ultimately reasonable, no emotion more satisfying than to achieve exact and quantitative verification after months of trial and experiment. Do not think, therefore, you who live amid the romance of helping your suffering fellow-men, that the new laboratories here are peopled with patient drudges, moved perhaps by intelligence but never by emotion. There may be as much real poetry, as much real magic, as much real romance, within these walls as a human life can hold.

It is a necessity of religions that they should have creeds but a failing of some of them that they make these too long and incredible. In science also, which is a form of religion, we need creeds, but let us take warning and keep them short. May I suggest one to Professor Bronk for the Johnson Foundation?

"I believe in young and intelligent minds; I believe in the value of careful experiment and observation, and in the very special virtue of accurate quantitative measurements; I believe in the utility of theories provided they be not regarded as facts; I admit the necessity of criticism and disbelief; I hope and pray for the damnation of those who are not strictly honest; and I am convinced of the complete reasonableness of natural phenomena."

Believing in these things as he and his colleagues do, rejoicing in the supreme opportunity supplied by the generosity and wisdom of those who gave and planned and executed, I foresee for them a future of work and adventure which cannot fail to bring rich fruit, to themselves and their colleagues in this, the oldest of American medical schools, and so to the rest of the world.

I must not let this afternoon go by without a word of thanks. You have treated me with much honor in asking me to address you on this great occasion. I wish I could have said something of more dignity and value, something more worthy of the years of work and forethought which have gone to make the occasion possible. It is strange that you should have thought to invite Sir Walter Fletcher and myself to address you on the same day. It is almost precisely a quarter of a century ago—within a week—that I became, by fortunate and romantic chance, his pupil at Trinity College, Cambridge. It is almost precisely a fifth of a century ago that, as the result of his advice to study physiology, I became a Fellow in our College. I know he regards me with a certain parental affection, as I him with filial pride: it has moved us deeply that after this quarter of a century we should be coupled, as you have coupled us today, in the honors you have done us. It is strange, too, that you should have asked me to speak on the same occasion as Dr. Welch. I have been honored by many kindnesses from Dr. Welch, and one of my treasured possessions is a photograph of himself dressed as a brigadier general in the American army. I understand that in spite of all his achievements, in spite of all the honors which have befallen him, in spite of his supreme rank in American medicine, he is sufficient of a schoolboy still to get more joy from the uniform of a brigadier general than from all the rest. If friends in England can make any one an Englishman, then Dr. Welch is one, so the strangest thing of all is that three Englishmen have been invited to address you today. Whatever your motive, I am inclined to think that it has something to do with a special item in the Scientists' Creed which I omitted before with the intention of including now: "I believe that the pursuit of knowledge, for the welfare of the race, is one of the greatest agents of good will between men in every land." Our theories may be wrong—which does not matter much—our observations may not prove accurate enough—which is bad—our experiments partial and misleading—which is awful; but the fact that we have marched side by side in an honest endeavor to conquer ignorance, that we have sailed the unknown seas together in search of adventure and truth, and that we have learned to understand and love one another not only as fellow workers but as fellow beings—these things cannot fail to draw us together and so to minister to the welfare and comradeship of the different varieties of men. Such at least is my firm faith. I see in science and medicine more hope of cooperation between the nations than in any other field of human endeavor; and some such motive, I imagine, inspired you to invite two Englishmen, and an honorary Englishman, to take part in this great and intimate occasion.

16 Bishopswood Road, Highgate N. 6.

The Bond Between Doctor and Patient.—Any reorganization of the medical profession that threatens the personal bond between doctor and patient is to be viewed with suspicion, even if the object appears at first sight to be more thorough and careful practice. With the exception of the relationship that one may have with a member of one's family, or with the priest, there is no human bond that is closer than that between physician and patient (or patient's family), and attempts to substitute the methods of machine or organization, be they ever so efficient, are bound to fail.—Peabody, F. W.: Doctor and Patient, New York, Macmillan Company, 1930.

THE DIAGNOSIS OF TUMORS INVOLVING THE SPINAL CORD *

HENRY W. WOLTMAN, M.D.
ROCHESTER, MINN.

I propose to limit my consideration of tumors involving the spinal cord to diagnosis, which is the phase of particular interest to medical men and which has, as its natural sequence, proper treatment. The patient's story is the most important step in diagnosis.

DIAGNOSIS

Pain.—The earliest and commonest complaint is pain. In more than 300 proved cases of tumor of the spinal cord at the Mayo Clinic, pain was present in approximately 80 per cent. The average duration of the symptom was well over two years. Frazier[1] noted the duration of the disease to be twenty-eight and four-tenths months. The pain may be in the spine at the site of the tumor; it may be referred to the lower extremities even when the tumor lies high in the canal, but usually it is referred along the distribution of a posterior root, when it is known as a root pain. It is the peripheral radiation of root pain and its various qualities, such as aching, squeezing or piercing, that so frequently suggests disease of the pericardium and pleura; of the biliary, urinary and gastro-intestinal tracts; of the peripheral nerves, and of muscles and bones.

Fortunately, root pains have certain characteristics. They are segmentally distributed; that is, lengthwise in the arms and legs and circularly in the trunk. Then, since tumors grow, the pain becomes more and more intense and adjacent roots become involved; unilateral sciatica becomes bilateral sciatica, and unilateral trunk pain has added to it a complementary pain on the opposite side, completing the so-called girdle. Since there are usually no diseased organs at the site of the pain, there is, as a rule, no local tenderness. Coughing, sneezing, compression of the jugular veins, or, in short, anything which suddenly increases the pressure of the spinal fluid aggravates the pain. Root pains have a habit of awakening the patient from sleep at 3 or 4 o'clock in the morning. He discovers that relief may be obtained by walking, or by sleeping in a chair. In both of these positions the spine becomes relatively shorter. A helpful test consists in flexing the head sharply on the thorax; this simple maneuver often elicits or accentuates the pain. The explanation is probably to be sought in the resulting traction on the cord and dura, and in the increased congestion within the head which displaces the cerebral fluid into the spinal canal. A blue pencil, which Richard Bright referred to as "the most useful instrument of the physician," will be found helpful. It is important to know the precise site of the pain, which may be marked on the patient. The dates of its appearance and its radiation should be recorded.

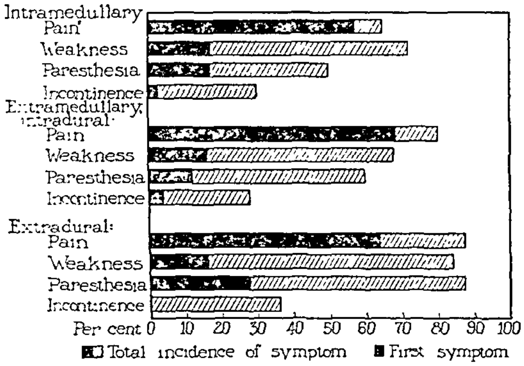

Fig. 1.—Frequency and order of appearance of four cardinal symptoms of intramedullary, extramedullary, intradural and extradural tumors involving the spinal cord.

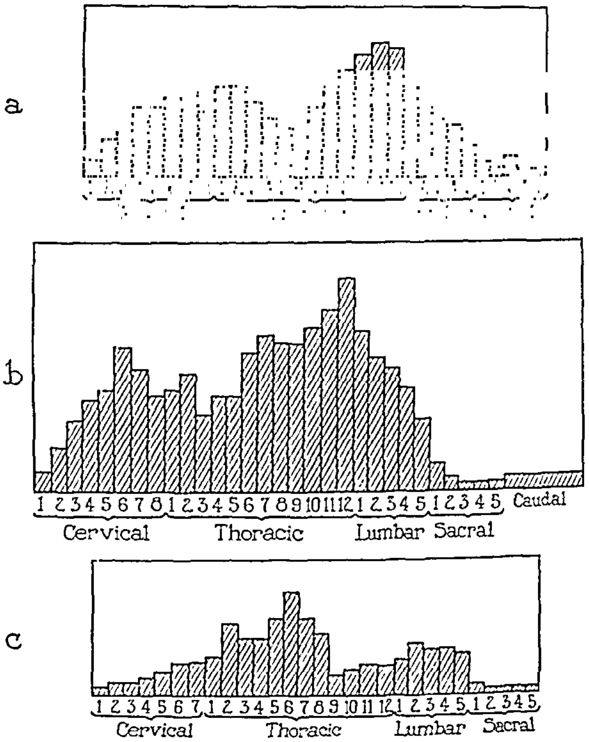

Fig. 2.—Incidence at various segmental levels of 312 tumors. Diagrams are based on Craig's figures: *a*, eighty-nine intramedullary tumors; *b*, 156 extramedullary intradural tumors; *c*, sixty-seven extradural tumors.

Disturbances of Motility.—By and by the patient may become aware of clumsiness in running, or of outright muscular weakness. As a rule, the weakness is slowly progressive. The weakness is usually due to injury of the corticospinal pathway, pyramidal tract, or upper motor neuron. The homolateral muscles below the level of the tumor, although they retain their bulk, become weak and spastic; the tendon reflexes are increased, and scratching the sole of the foot results in extension of the great toe. Inspection of the tips of the patient's shoes may show a decided difference in wearing.

Sometimes the paralysis is due to direct injury of the contiguous anterior horn cells or ventral roots, which together constitute the lower motor neuron. If this occurs, the segmentally related muscles fibrillate and become atrophied, weak and toneless, and their reflexes become correspondingly feeble. By consulting suitable charts, the level of the nerve cells that innervate muscles so paralyzed may be determined. This type of paralysis is the best of localizing signs.

Some patients collapse suddenly, arise, and wonder why they fell; this often happens in case of dumb-bell-shaped tumors which lie partly within and partly without the spinal canal, and may be due to transitory compression of the cord. Other patients who become suddenly weak may have suffered from hemorrhage or softening of the cord incidental to the tumor.

* Read before the Section on Practice of Medicine at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

[1] Frazier, C. H.: Surgery of the Spine and Spinal Cord, New York, D. Appleton & Co., 1918, pp. 498-608.

Disturbances of Sensibility.—Subjective sensory disturbances appear sooner or later. The patient may complain that his underwear is unbearably irritating; the feet may be "dizzy"; the limbs may move to unanticipated positions; there may be burning, tingling, or a wooden sensation. These disturbances result from interference with the posterior roots or conducting tracts in the cord, as will become apparent in the accompanying reports of cases.

Disturbances of Sphincteric Control.—Disturbances in the sphincteric and sexual spheres may add to the discomfort of the patient. That these complaints do not vary greatly with the situation of the tumor is shown in figure 1.

Following spinal puncture, aggravation of all symptoms is common; a neurologic examination may then enable one to establish a level of disturbance with ease when it was impossible before.

ILLUSTRATIVE CASES

Although the history of the case leads one to suspect tumor, the diagnosis rests largely on the objective examination. A working knowledge of the anatomy and physiology involved must be the guide. Three cases, in which tumors were found at different segmental (fig. 2) and transverse (fig. 3) situations,[2] will help to illustrate some of these points.

CASE 1.—A man, aged 32, who was left-handed, complained of paralysis of the left arm. Four months previously he had noted an aching pain in the left occipital region, which was present on awakening and gradually wore away after he had eaten breakfast. He had become constipated and had found that he could not void urine until his bladder had become well filled. Three months before his admission to the clinic he had noticed that the left arm felt heavy and that he had to look carefully at an object when he attempted to pick it up with his left hand; otherwise it would escape his fingers. He had become aware of a slipping sound made by his left foot when he walked. One evening, much to his surprise, he had stepped with the left foot into a scalding hot bath, which, tested with the right hand, had seemed to be neither hot nor cold. Subsequently, the right half of the body had tingled constantly. On occasions he had vomited unexpectedly. The story was one of progressive disability, beginning with pain in the left occipital region, followed by vague sphincteric disorders, impairment of joint sensibility in the left hand, left hemiparesis, right hemithermanesthesia, and symptoms which suggested increasing intracranial pressure.

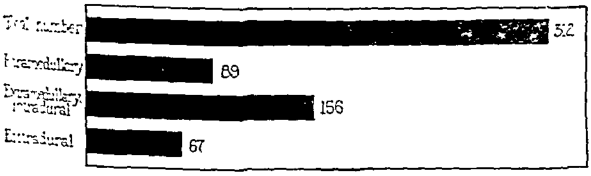

Fig. 3.—Transverse positions of tumors, based on Craig's analysis.

Over the right half of the body below the distribution of the fourth cervical segment there was loss of appreciation of pain and temperature, but appreciation of touch was normal throughout. Since painful and thermal stimuli cross to the opposite side of the cord, their loss on the right side suggested involvement of the tracts which conduct these forms of sensation, that is, the left lateral spinothalamic tract. Since tactile stimuli ascend partly in the homolateral posterior column and partly in the opposite anterior spinothalamic tract, their preservation indicated that at least one of these pathways was intact. The left arm and leg, although they were normal in bulk, were paralyzed and spastic, and displayed increased tendon reflexes and extension of the great toe on plantar stimulation. This indicated injury to the left pyramidal tract. The faulty perception of movements of the joints and of vibration in the left upper extremity indicated that the lesions involved the lateral aspect of the left (fac. cuneatus) posterior column. In other words, Brown-Séquard's syndrome, which is indicative of a lesion affecting one side of the cord, was well developed. The drooping eyelid and small pupil on the left, Horner's syndrome, were due to paralysis of the sympathetic fibers and indicated a lesion not lower than the first or second thoracic segments, since no sympathetic fibers leave the cord above this level. The left sternomastoid, trapezius and nuchal muscles were weak, atrophied and fibrillating, which indicated involvement of lower motor neurons. Since these muscles are all innervated by cells of the first four cervical segments on the same side, a sharp localization became possible. Over the left occipital region in the territory of the posterior root fibers of the second cervical nerve, appreciation not only of pain and temperature but also of touch was lost. These phenomena localized the lesion sharply to the left side, in the region of the first and second cervical segments. The projectile vomiting was probably caused by encroachment of the lesion on the foramen magnum. Since the history indicated progressive involvement, tumor was the most likely cause.

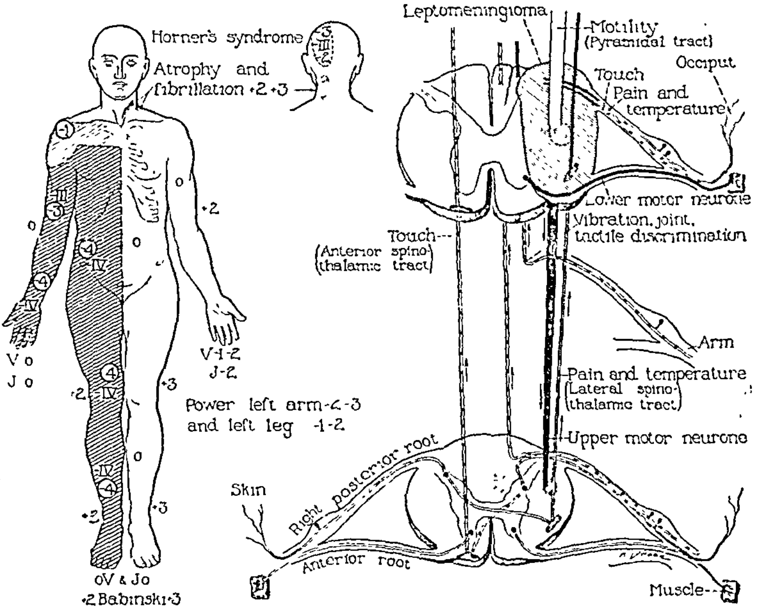

Fig. 4.—Illustrating data noted in case 1. In this figure and in figures 5 and 6 the intensity of changes is charted on a basis 0 to 4, 0 indicating normal, 4 complete absence. Arabic figures represent appreciation of touch; encircled Arabic figures, pain; Roman figures, temperature. Injured pathways in this figure and in figures 5 and 6 are in solid black. Extramedullary intradural tumor on the left side at first and second cervical segments.

Subtotal removal of a malignant meningioma was followed by marked temporary improvement, but the growth recurred later.

Tumors in the upper end of the spinal canal may present certain peculiar features. The exposed situation of the decussating pyramidal tracts on the anterior aspect of the cord, in the presence of a tumor, may result in a quadriplegia unaccompanied by any sensory disturbance. The sensory disturbances associated with high cervical tumors may be limited to the lower extremities or may fluctuate from time to time and from place to place, probably because the canal is relatively large. Involvement of the descending root of the fifth nerve may result in pain referred to the face and in anesthesia for pain and temperature over certain districts of the face, particularly over the forehead. The proximity of the tumor to the foramen magnum may bring about signs of tumor of the brain, such as projectile vomiting and choked disks.

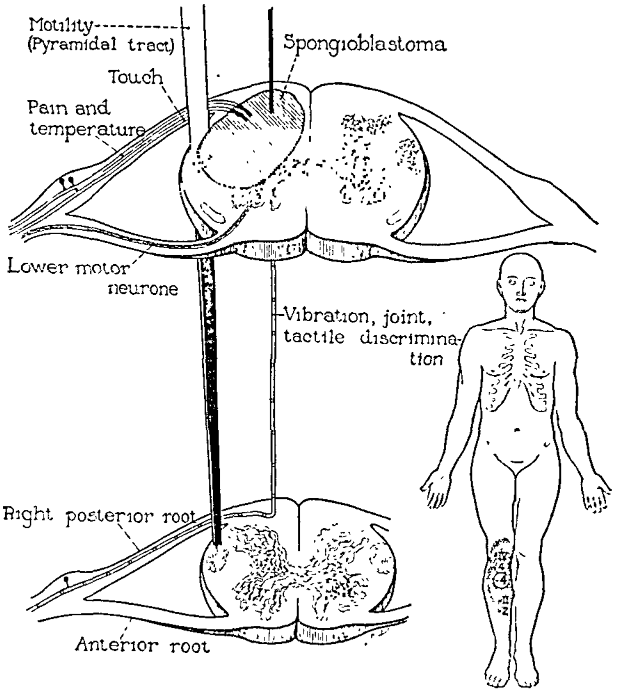

Fig. 5.—Intramedullary tumor, left side, at second to fourth lumbar segments.

Case 2.—A man, aged 58, came to the clinic because of pain in the right leg. Six years before, a "pinching" pain had appeared under the right knee cap when he sneezed. The pain had grown in intensity, had gradually extended to the anteromedian aspect of the right thigh, and had been especially severe at night. His wife had tried to relieve him by "ironing" the leg. The iron had been too hot for the thigh but he had "stood it well" on the knee. The following morning they had discovered large blisters over the knee. Numbness had developed in the right great toe and had gradually crept up the anterior aspect of the leg. For four years this leg had grown stiff and awkward, and he had stumbled frequently. Two years previously he had soiled himself during an attack of diarrhea.

Examination disclosed slight weakness of the right leg (fig. 5), particularly of the iliopsoas, hamstring and extensor muscles of the toes, and occasional fibrillary tremors in most of the visible muscles of this limb. The gait was slightly spastic and ataxic on the right side. The right patellar reflex was absent, a good localizing sign, but the right achilles tendon reflex was more active than the left, and the right great toe turned up on plantar stimulation. Evidently the lesion involved the second to the fourth lumbar segments, which subserve the arc of patellar reflex, and the right pyramidal tract. There was impairment of all forms of cutaneous sensibility mediated through the posterior roots of the right third and fourth lumbar nerves, and of vibration, joint and tactile discrimination, below this level, mediated through the homolateral posterior column; for example, when the patient was asked to place a finger on a point previously touched by the examiner, he missed it by 16 cm.; when asked to count the number of rapidly applied stimuli, he did so inaccurately; he could not recognize figures drawn on the skin; he could not recognize two points of a compass, applied simultaneously to an area, unless they were separated more than 6 cm. However, a separation of 2.2 cm. sufficed over the corresponding area on the left leg.

A diagnosis was made of tumor of the cord, probably extramedullary, at the level of the third and fourth lumbar segments, which lie opposite the body of the eleventh thoracic vertebra on the right side. On exploration a poorly defined intramedullary spongioblastoma was found, evidently situated more on the right side of the cord than on the left.

The case illustrates, among other things, the difficulty of distinguishing between intramedullary and extramedullary growths.

Case 3.—A man, aged 29, came to the clinic because of "sciatic neuritis." Three years before, on a morning following a dance, he had been unable to get out of bed because of general malaise, fever, and intense pain in the lumbosacral region, which radiated down the posterior aspect of the left thigh. For nine days he had remained helpless in his shack and had "almost frozen to death," for the temperature had dropped to — 36 F. After three weeks he had returned to work but the pain had persisted. Work had aggravated the pain but he could "tell when the sun set and rose" because of the nocturnal incidence of the pain. Two months before examination, he had noticed a crawling sensation over the posterior aspect of the left thigh.

Many features of the story suggested sciatic neuritis, but other possibilities were indicated. There was a marked list of the spine toward the right. Flexion of the extended leg on the thigh (Lasègue's test) increased the pain, as did sharp flexion of the head on the thorax. The left achilles tendon reflex was absent. Appreciation of pain, temperature and touch were impaired, as indicated in figure 6. The spinous processes of the second and third lumbar vertebrae were slightly tender, but the sciatic nerve was not tender.

Influenced by the course of the illness and the site of the anesthesia, a diagnosis was made of tumor of the cauda equina with involvement of the left second, third and fourth sacral roots. The exact level was difficult to determine, since the tumor might be situated anywhere between the body of the first lumbar vertebra, at which level these roots spring from the cord, and the sacral foramina, where these roots leave the spinal canal.

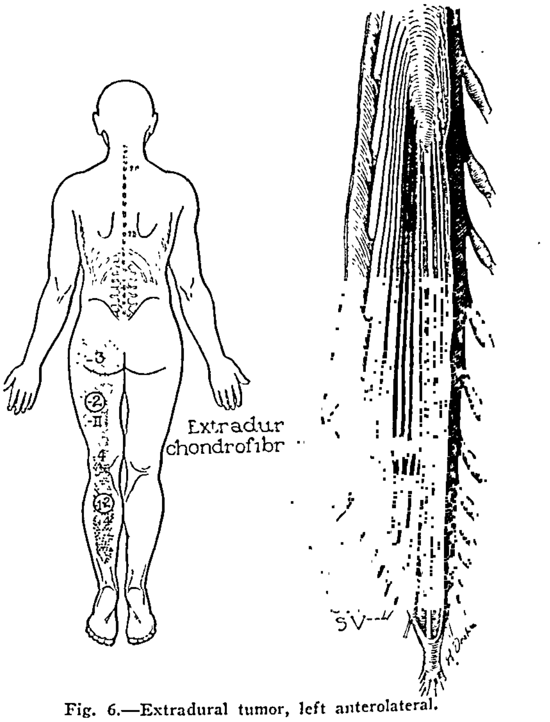

Fig. 6.—Extradural tumor, left anterolateral.

Laminectomy was performed and a spherical chondrofibroma was found, anterior to the dura, to the left of the median line, arising from the fifth lumbar intervertebral disk and obstructing two thirds of the lumen of the spinal canal.

In tumors in the lower end of the spinal canal, the long intraspinal course of the lumbar and sacral nerves makes it extremely difficult to determine the exact level of the disturbance and whether there is a tumor of the cord, of the cauda, or of the sacrum. The neurologic data may be the same in all cases.

The data obtained by spinal puncture, roentgenologic examination, and rectal examination usually obviate serious blunders.

HYDROSTATIC AND CHEMICAL CHANGES OF THE SPINAL FLUID

On the basis of experimental evidence, Sachs[3] concluded that the spinal fluid is practically without circulation. The slightest change in pressure at any situation is, however, transmitted throughout the remainder of the fluid. Because of the limited space in the spinal canal, a growing tumor eventually interrupts the continuity of the fluid in the subarachnoid space. Such blocking may in most cases be demonstrated by a simple maneuver described by Queckenstedt[4] in 1916. We are indebted, particularly to Ayer,[5] Stookey,[6] Elsberg[7] and Davis and Pollock[8] for contributions of far-reaching clinical importance.

When the spinal puncture needle and the attached manometer are in place, pressure on the jugular veins normally causes a rise in the column of fluid in the manometer, owing to filling of the intracranial venous channels, with consequent displacement of cerebrospinal fluid along the spinal subarachnoid space, through the needle, into the manometer. Release of the pressure on the veins results in prompt fall of the column of fluid in the manometer, owing to a return to previous hydrostatic conditions. When the pathway of the fluid in the canal is obstructed by a tumor, the degree of interference is registered by the column of fluid in the manometer. Should the tumor lie low in the canal, the needle may pierce the tumor and a dry tap result, or the needle may enter the canal above the tumor. When this occurs, block may sometimes be demonstrated by injecting a saline solution into the epidural space by way of the sacral hiatus, and noting the result produced in the manometer.

The fluid obtained from the canal below a tumor is often yellow. The fluid may also be yellow above the tumor, but the color here is usually lighter than below. The content of globulin in the fluid is almost invariably increased. The total content of protein in the fluid in cases of tumor is usually high, whereas that of fluid loculated by adhesions, in which a block may also exist, usually approaches normal. The removal of 7 cc. of fluid normally results in lowering the basal pressure of fluid about half; when the fluid is loculated, the fall in pressure is usually great.

ROENTGENOGRAPHY

Roentgenography occasionally reveals erosion of bone produced by a tumor, or even a calcified tumor itself. Roentgenography is also one of the most certain methods of excluding metastatic tumors and other diseases of bone. The introduction of an opaque medium, such as iodized oils, into the subarachnoid space through cisternal or lumbar puncture usually does not help a difficult situation. When the block due to tumor is sufficiently complete to arrest the oil in its descent, the situation of the tumor usually can be determined without its use; when block is not so complete, the oil may sometimes be seen by aid of the fluoroscope to deviate from its course. Its use in differential diagnosis is limited, and iodized poppy-seed oil 40 per cent, which is the preparation commonly used, is somewhat irritating to the meninges.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis may be difficult. Various inflammatory (suppurative, nonsuppurative, parasitic, granulomatous) malignant and post-traumatic involvements of the cord, membranes, roots, and spinal column come into question, as do degenerative diseases of the cord. Multiple sclerosis deserves special mention, since it may be suggestive of a transverse lesion of the cord and since tumors high in the vertebral canal may simulate multiple sclerosis. Syringomyelia may be difficult to distinguish from intramedullary tumor, and the two may be present in the same case. The spinal cord and roots may be compressed in hypertrophic osteitis and hypertrophic arthritis of the spinal column and in Paget's disease. Spina bifida occulta may be associated with traction and compression bands that lead to progressive paralysis and even with tumor. Spondylolisthesis, or slipping forward of one vertebra on the other, usually the fifth lumbar on the sacrum, may be detected without difficulty by means of roentgenography.

The occasional loss of the patellar reflexes in cases of tumor sometimes leads to the erroneous diagnosis of tabes. Root pains cause the greatest confusion, particularly when disease of the gallbladder, or of the genito-urinary or gastro-intestinal tracts, is associated with tumor of the cord. Retroperitoneal and mediastinal tumors, particularly aneurysms, and leukemic and lymphoblastomatous infiltrations of the cord, provide pitfalls when short-cuts in the examination are attempted. Sometimes edema of the lower extremities is so prominent a feature that cardiac or renal insufficiency is diagnosed.

Repeated examinations may be necessary in order to establish a diagnosis. Occasionally exploratory laminectomy is advisable, particularly if progressive involvement of the cord makes further delay perilous. However, exploration without definite indication of the correct level of disturbance is almost certain to result in disappointment.

ABSTRACT OF DISCUSSION

DR. J. B. AYER, Boston: I have investigated sixty-four cases of tumor involving the spinal cord. These cases of primary tumors give the following figures as to the appearance of symptoms: In eighteen cases of intramedullary tumors, mostly glioma, twenty-six months elapsed before an operation was undertaken, on the average. In thirty-three cases of meningioma, that is, extramedullary tumor arising from arachnoid or from nerve root, twenty-four months elapsed. In four cases of epidural tumor, eight months on the average elapsed before operation. And in nine cases of tumor arising from the intervertebral disk, that is, chondromas, thirty months elapsed. These figures agree closely with the figures Dr. Woltman has given as his average. It is not too satisfactory that these patients should have gone so long when on looking back over the records one can detect symptoms that were highly suggestive and signs which Dr. Woltman has given that were quite characteristic. I will plead guilty to postponing operation on two of these patients. With regard to the symptoms and the signs as given by Dr. Woltman, I can only say that I agree in every way. Pains are usually the earliest symptoms in most cases, in thirty-seven of my series; they are often localizing in value. Atrophy and atrophic paralysis are localizing signs of great value: in four cases of my series and in one case the only real localizing point on which operation was based. The sensory level is a point to be sought for and freqnently is not found. In fifteen of my sixty-four cases a satisfactory sensory level could not be made out. In this group of fifteen cases, and in others in which confirmation is desired, one must turn to other diagnostic aids, and I refer particularly to the use of iodized oil for that purpose. I have used iodized oil in twenty-six of the sixty-four cases. I have had only temporary ill effects from its use. In three cases it was not helpful, as far as my interpretation was concerned. In two the level appeared incorrect and in one the iodized oil passed by a tumor. But that may have been due to technic. I always use the fluid estimation of block, as Dr. Woltman has outlined, and believe it to be a delicate method of determining whether or not there is cord compression. Iodized oil should be used in connection with this if the level is indefinite.

Dr. C. H. Frazier, Philadelphia: There is a striking difference between brain and spinal cord tumors. In the latter, difficulties arise chiefly in differentiating tumor from other lesions, whereas in brain tumors the difficulty lies chiefly in localization. Generally, recognition of spinal cord tumors is not difficult, but there are notable exceptions. I feel that more is learned from failures than from accomplished successes. I therefore reviewed some cases in which at operation I failed to find tumor and was struck particularly by the fact that in none was there a typical history of spinal cord tumor. In most cases the tumor is extramedullary; there is a definite sequence of symptoms, of pain, paresthesia and paralysis, although Dr. Woltman places the motor phenomena before the sensory. I was glad he and Dr. Ayer stressed pain as a conspicuous phase. To me this is an especially informing guide to diagnosis and to localization; usually the first symptom to appear referred from the onset to a constant zone and, while the pain zone may spread with tumor growth and involvement of more roots, the patient always complains of pain at the point at which he first experienced it. Theoretically, there are three cycles in the spinal cord history: the pain or root cycle, the Brown-Séquard cycle and the transverse cycle. Most of the mistakes in my series have been in cases of multiple sclerosis, when many of the typical symptoms are absent and the differentiation is not easy. But I have found that there are several important differentiating points. In multiple sclerosis the history is longer, the progress of the disease is slower. There is no definite sensory level and there are marked remissions not present in tumor of the spinal cord. Mistakes ought not to be made in cases of syphilitic lesions. Patients who suffer most from failure to recognize the source of pain are those with metastatic carcinoma of the spine, prolonged, intolerable, intractable pain, unrelieved by morphine. Finally, syringomyelia may occasionally be mistaken for intermedullary tumor but the presence of syringomyelia does not necessarily exclude the propriety of a laminectomy. Only recently I had the most gratifying results from exposing and draining a large cyst of a cervical cord. There will always be cases in which there is justification for operating in the presence of a reasonable doubt. The surgeon is often faced with a difficult situation when confronted with a case which does not run true to form, but failing to find a tumor at operation there usually are three distinctive features: the patient did not have a typical tumor history, he did not have the characteristic pain phenomena, and he did not have a definite, unmistakable sensory level.

Dr. Loyal Davis, Chicago: There is a tendency for every one to attempt to find a group of symptoms that always mean spinal cord tumor rather than to arrive at a diagnosis of a lesion of certain tracts or cells within the spinal cord at a given level. Such a diagnosis may be made with a complete disregard for the actual nature of the lesion. For example, loss of the deep tendon reflexes, flaccid paralysis, muscular atrophy, and a reaction of degeneration mean the presence of a lower motor neuron lesion. There can be only three sites for such a lesion, and those are the peripheral nerve, anterior roots and anterior horn cells of the spinal cord. The absence of loss of sensation will rule out a peripheral nerve lesion. Anterior root lesions are so rare that they may be disregarded practically. The anterior horn cells are left. This is a horizontal diagnosis and the muscles involved will afford the vertical or segmental level diagnosis. Because a spinal cord tumor requires differentiation from every degenerative disease of the spinal cord, other diagnostic methods may be used to enable one to state definitely before operation that a tumor is present. He has mentioned manometric studies, which includes the Queckenstedt test. Certainly a spinal puncture should never be done for diagnostic purposes unless complete manometric readings are made. The demonstration of the presence of a subarachnoid space block is of extreme importance. The study of the protein content of the fluid above and below a tumor even though a partial block is present is often the deciding diagnostic factor. Dr. Woltman's experience with the injection of iodized oil into the subarachnoid space as an aid in the diagnosis of a tumor is similar to mine. It is a diagnostic procedure that is accompanied by danger and one that is unnecessary. It is well known that if water is poured into a number of connected tubes the surfaces of the liquid will lie in the same plane in each of the tubes. If one of the tubes is sealed at a given level, the introduction of fluid into the tubes will be followed by an increased rise of the fluid level in the unsealed tube. It is not even necessary to deal with rigid tubes. One of them may not be rigid and this fact will still be true. The spinal dural sac lends itself to a study of this hydrodynamic principle. After a lumbar puncture on the patient in the sitting position, the needle is connected in a fluid circuit with a syringe and buret. A given amount of saline solution may then be introduced successively into the dural sac. Each rise of fluid in the buret is recorded. It has been shown that there is an immediate multiplication of the rise in the buret as soon as the block in the subarachnoid space is reached. The amount of each injection of fluid has, of course, remained constant. This level on the buret is measured on the patient's back above the site of the puncture. I have been able to verify the clinical localization beneath a given spinous process in several instances at operation.

Energy and Metabolism.—The sum total of energy remains constant in the universe, but energy may vary in kind. The source of energy on the earth is the sun, excepting the energy of the tides, which is due principally to the moon. The sun unevenly warms the atmosphere, producing winds which drive ships and windmills. The sun's heat lifts the vapor of water into the atmosphere, producing rain, in consequence of which rivers are made to turn machinery. The sunlight acts upon a mixture of hydrogen and chlorine gas, causing them to unite with a loud explosion, and the sun acts upon the green leaf of the plant, causing it to unite carbon dioxide and water, with the production of formic aldehyde, which is built up into sugar, oxygen being given off in the process. The sun's energy required to build up the compound becomes latent or potential in it. Whenever and wherever this sugar is again converted into carbon dioxide and water by oxidation, exactly the same quantity of energy taken from the sun and made potential in the sugar is set free. This sugar in the plant may be further converted into starch, cellulose, fat, and possibly into protein. Plants furnish wood and coal as fuel for the steam-engine. They also furnish the basis of animal food yielding substances which can build up animal tissues, and which can furnish the energy necessary to maintain those motions in the cells whose aggregate is called life.—Lusk, Graham: The Elements of the Science of Nutrition, Philadelphia, W. B. Saunders Company, 1928.

INTRAVENOUS UROGRAPHY BY MEANS OF THE SODIUM SALT OF 5-IODO-2-PYRIDON-N-ACETIC ACID[*]

MOSES SWICK, M.D.
NEW YORK

In 1923 Rowntree and his co-workers[1] of the Mayo Clinic were the first to attempt to visualize the urinary tract by means of the intravenous injection of a 10 per cent solution of sodium iodide and also by the oral administration of that salt. The urinary bladder, and in some cases the pelvis and ureter, could be visualized.

The following year Rosenstein and von Lichtenberg[2] reported at the urologic congress in Berlin their results, repeating the work of Rowntree and his co-workers with sodium iodide but in conjunction with perirenal pneumoradiography.

In the same year Volkmann[3] reported his observations with the use of different halogen compounds; he found the intravenous injection of a 10 per cent solution of sodium iodide to be best.

In 1927 Lenarduzzi and Pecco,[4] tying off the ureter and injecting sodium iodide intravenously in animals, obtained positive roentgenograms of the kidney, pelvis and ureter.

Hryntschak[5] at the urologic congress in Berlin in 1928 and in a publication in 1929[6] reported his results with the use of a large series of bromine and iodine compounds, aromatic in nature, carrying out about 200 animal experiments. Neither the names nor the chemical formulas of the substances used by him are stated. In his publication the only detail of the chemical composition of three of them applied and numbered 13, 27 and 48 is that the first two were iodine and the last a bromine compound. In some of his experiments he simultaneously used an adjuvant, such as caffeine, urea, pituitary extract and atropine, to influence excretion and the dynamics of the pelvis and ureter. He obtained some positive results in animals and in a female patient. In his conclusions he stated that although, two and a half years ago, he had been able to obtain useful intravenous pyelograms in a few cases, the method had by no means met the conditions set forth by him. He, however, expressed the hope of accomplishing his aims by continued investigations.

Ziegler and Köhler[7] reported at the urologic congress in Munich in 1929 and in a publication in 1930[8] their results with the oral administration of 10 Gm. of sodium iodide and 10 Gm. of urea in milk in conjunction with pressure applied over the sacro-iliac articulation through the abdominal wall by means of a special apparatus.

Roseno[9] was the first to achieve practical results by means of the intravenous use of a combination of sodium iodide and urea, called "Pyelognost" [NaI, $CO(NH_2)_2$]. According to some reports it is stated that the substance employed by him is at times associated with reactions. The visualization of the urinary tract, however, is satisfactorily accomplished. Roseno also stressed the functional aspects of the problem. He gave an account of his investigations at the urologic congress in 1928. In 1929 he made a further presentation of his work before the urologic congress in Munich and published an extensive report of the method and the results. In the course of a discussion at the time of the first presentation, von Lichtenberg[10] expressed himself pessimistically concerning the possibility of intravenous urography.

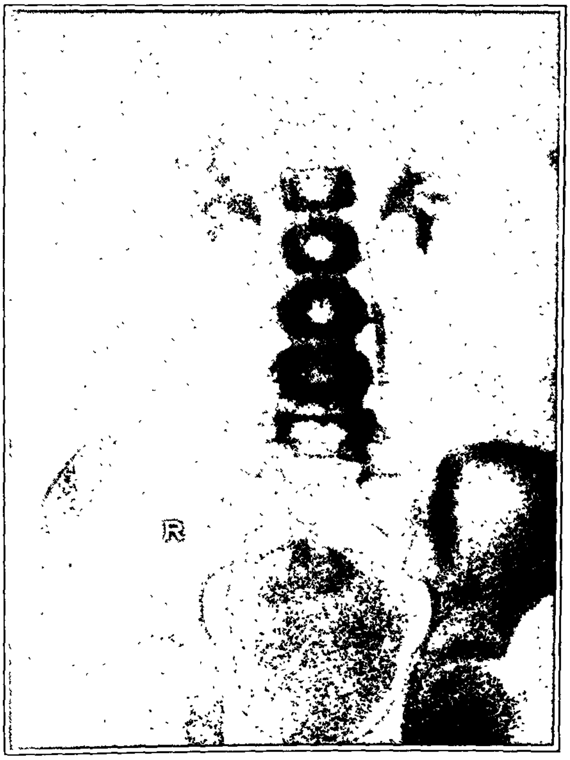

Fig. 2.—Intravenous urogram to exclude right urinary calculus, in a girl, aged 8 years. Slight dilatation of right kidney pelvis and blunting of calices (pyelitis). 25 Gm. of substance.

This work[11] was begun with N-methyl-5-iodo-2-pyridon, synthesized by Professors Binz and Räth.

At the wish of Professor Binz, the efficacy of this substance in the therapeusis of streptococcus infections was under investigation in the clinic of Professor Lichtwitz in Altona, Germany. The study of its excretion through the kidney and into the bile and its iodine content (54 per cent) led to the thought that the substance might be applicable for roentgenologic purposes. Experiments on rabbits demonstrated the fact that the kidney parenchyma and urinary bladder could be visualized after the intravenous injection of the drug; the pelvis and ureter, on the other hand, were poorly seen. Ligation of the latter, however, did bring the upper tract well into view. The gallbladder was not visualized. Simultaneous studies of its excretion, limited to determinations of the iodine component, revealed about 75 to 80 per cent of the injected iodine in the urine in from twelve to sixteen hours.

Concerning the toxicity and tolerance, I found that 0.2 Gm. per kilogram of body weight could be administered intravenously to the rabbit without any demonstrable ill effects; 0.33 Gm. per kilogram, however, produced transient generalized disturbances. On the basis of these observations, one could theoretically give to a 60 kilogram individual 18 Gm. of the substance as a maximal dose. Because of marked individual differences in man, the quantity administered was far below the calculated one. The adult received 6 Gm. of substance. Headache, nausea, vomiting, generalized discomfort, and in two cases transient diplopia were disturbing factors. The oral and rectal administration of this drug also yielded similar roentgenologic results and toxic manifestations. In all cases the urinary bladder was seen. The kidney parenchyma itself appeared to stand out more in relief. In man, the upper urinary tract was outlined only after producing a temporary artificial obstruction in the ureter by means of a bougie at the time of maximal excretion. The attained results, though not sufficiently good for practical purposes, were encouraging and pointed to the possibilities of further development.

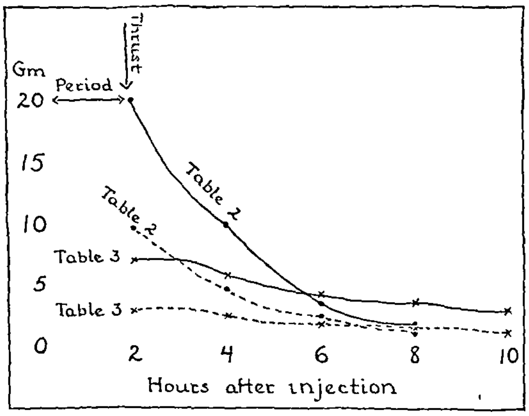

Fig. 3.—Excretion of normal and of abnormal kidneys, 50 Gm. dose, tables 2 and 3: solid line, weight of precipitable acid excreted, in grams; broken line, weight of iodine excreted.

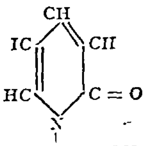
The experience with this substance brought out the need for a modification, possessing better tolerance and greater solubility, so that a larger dose could be administered. In this way, a higher concentration of the excreted iodine component could be hoped for. The observation of double vision and the possibility that the methyl radical might be responsible were noted. At a conference between Professor Binz and his associates, Professor Lichtwitz and me, these results and observations were presented. Professor Binz, who followed these investigations with great interest, said that he felt that these needs could be fulfilled. He supplied us with several compounds which he states belonged to the selectan group, synthesized by him and Professor Räth at an earlier date, and which now were prepared in larger amounts for our purpose and studies with the aid of Dr. Hillgruber.[12] One of them, insoluble in water, was soluble in very strong alkali. It could not be given intravenously and was therefore administered by mouth to a dog and in gelatinum duratum capsules to a male patient at Professor Lichtwitz's clinic with negative results. Professor Binz had furnished me with this drug one week before the conference mentioned.

Thereafter I continued the work in the urologic service of Professor von Lichtenberg in Berlin. To eight patients, 7.5 Gm. of the original substance, N-methyl-5-iodo-2-pyridon, were given by mouth with the already described reactions. The outline of the bladder was seen. Only in one case, that of a stone obstruction of the ureter about one inch below the ureteropelvic junction, was a useful roentgenogram of the pelvis and ureter above the stone obtained. The insoluble compound used at Professor Lichtwitz's clinic was now tried again at Professor von Lichtenberg's division with the same negative results. Another compound of this group, having a higher iodine content and a sodium acetate radical substituted for the methyl, was then tried. Though more soluble than the previous one, it was still unsuitable for intravenous application. The oral administration was likewise inadequate because of the poor absorption by the gastro-intestinal tract. When a preparation having a lower iodine content and the sodium acetate group substituted for the methyl was furnished by Professor Binz, the clinically applicable and successful substance, 5-iodo-2-pyridon-N-acetate of sodium, was finally obtained. This compound differs from the original only in the substitution of sodium acetate in place of the methyl group. It was fortunate that this preparation, introduced abroad as "Uroselectan," proved to be free from all accompanying reactions, to have quite an extraordinary affinity for the kidney, and to be very soluble in water. These needs were therefore completely fulfilled and satisfactory roentgenograms could now be obtained, as reported by me at the urologic congress in Munich in 1929.[11] Professor von Lichtenberg, who took up the subject directly after me, stated that he considered that which had been communicated a significant advance.[13] Some weeks later, my paper was published in the *Klinische Wochenschrift* and was followed by another contributed by Professor von Lichtenberg and me.[14]

The 5-iodo-2-pyridon-N-acetate of sodium (42.2 per cent iodine) is nontoxic, very soluble in water and *neutral in its reaction.*



The iodine in the molecule exists in a stable organically bound state. Neither in the injected solution nor in its excreted form is iodine present in ionized state. These facts, despite the relatively large quantity of iodine in the amount of this substance that can be administered with impunity, would seem to explain, at least empirically, why iodism has never been observed. The tolerance for this compound is exceedingly great. A rabbit would receive 3 Gm. per kilogram of body weight without any harm. With the latter dose as a basis of calculation, it follows that 180 Gm. of the substance, or, in terms of iodine, 75.6 Gm., can be theoretically administered to a 60 kilogram person. The substance is excreted as such through the urinary tract, being recovered from the urine as the light yellow, insoluble acid on the addition of a dilute mineral acid. Because of the relative simplicity and accuracy and because I found it to be of assistance in the evaluation of the roentgenologic results, it has been considered feasible to apply a quantitative determination of this insoluble, precipitated acid-form as a basis for a test of renal function.

Percentage of substance excretion					91.23 per cent
Percentage of iodine excretion					95 per cent

* A woman, 25, with good renal function; 50 Gm. of substance injected.

The recovery and identification of the excreted substance have been established in the following manner:

The addition of a dilute mineral acid—HCl or H_2SO_4—to urine containing the excreted soluble salt of the 5-iodo-2-pyridon-N-acetic acid results in the precipitation of the insoluble acid form. The precipitating agent should be added gradually until no more precipitation occurs. After one hour's settling, the insoluble acid is filtered by means of suction on a Buchner funnel and is washed free from the precipitating agent with distilled water, as determined by the silver nitrate test for hydrochloric acid or the barium chloride test for sulphuric acid. The residue is dried to a constant weight at 80 C. For identification, a variety of samples of the urinary precipitate were analyzed for their iodine and nitrogen content; their acid equivalents and melting points were also determined. These were simultaneously controlled by comparison with similar determinations on substance precipitated from clean manufacturer's samples of the sodium salt.

Percentage of substance excretion					53 per cent
Percentage of iodine excretion					52 per cent

* A woman, aged 42; 55.5 Gm. of substance injected.

The brown color of the precipitate, recovered from some of the urines, is believed to be due to the admixture of urinary pigment; this is demonstrated as follows:

1. If animal charcoal is added to boiling water containing the brown colored acid-form in solution, the recrystallized substance no longer is brown; it now is light yellow, resembling pure precipitate.
2. Conversely, when a manufacturer's sample of the solution of a sodium salt is added to normal urine and then the acid form precipitated from it (a procedure analogous to that of the recovery of the substance from the urine), the precipitate obtained is then brown. The same pure solution, however, with the addition of acid alone, yields a light yellow precipitate.

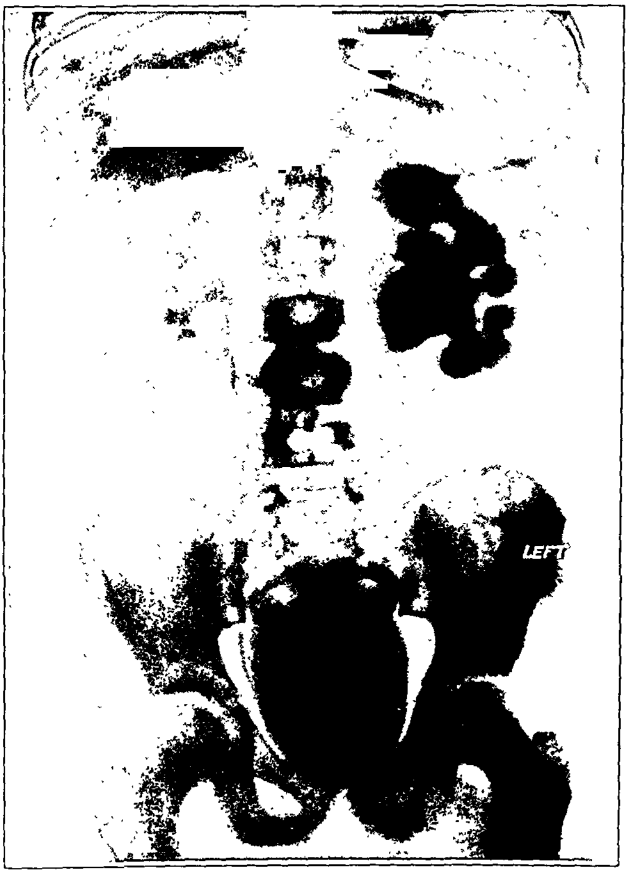

Fig. 5.—Marked dilatation of ureter, kidney pelvis and calices in a boy, aged 10 years. 25 Gm. of substance. (Case of Drs. Leopold and Stewart of the Lenox Hill Hospital, New York.

3. Qualitative analysis of the precipitate, following the scheme for the examination of urinary calculi, is negative for nonpigmentary urinary constituents.

The next consideration is whether the precipitation is quantitative. To determine this, two hour urine specimens of patients injected with a known amount of the sodium salt were collected. On each specimen two simultaneous determinations were made, one for its iodine content by a sodium carbonate and sodium nitrate fusion method; the other by precipitating the acid and determining its constant weight. Since the acid by molecular weight contains 45.5 per cent of iodine, the quantity of iodine found by multiplying the weight of the precipitated acid by 45.5 should correspond to that of the total iodine determined directly from the urine. Tables 2 and 3 illustrate the results obtained.

Comparing columns five and six, that is, the calculated iodine values with the independent iodine determinations, one observes a constant, close agreement. The reason for the relatively small differences between the calculated (the lower values in column 5) and the quantitatively determined iodine (column 6) can be explained by the presence of the precipitated acid form in the filtrate as a result of its slight solubility. It has been found that the iodine content of the filtrate plus the calculated iodine compare very favorably with that of the quantitatively determined iodine. There were isolated cases in which there were discrepancies, believed, however, to be due to an error in the technic of iodine determination. This phase is being investigated further.

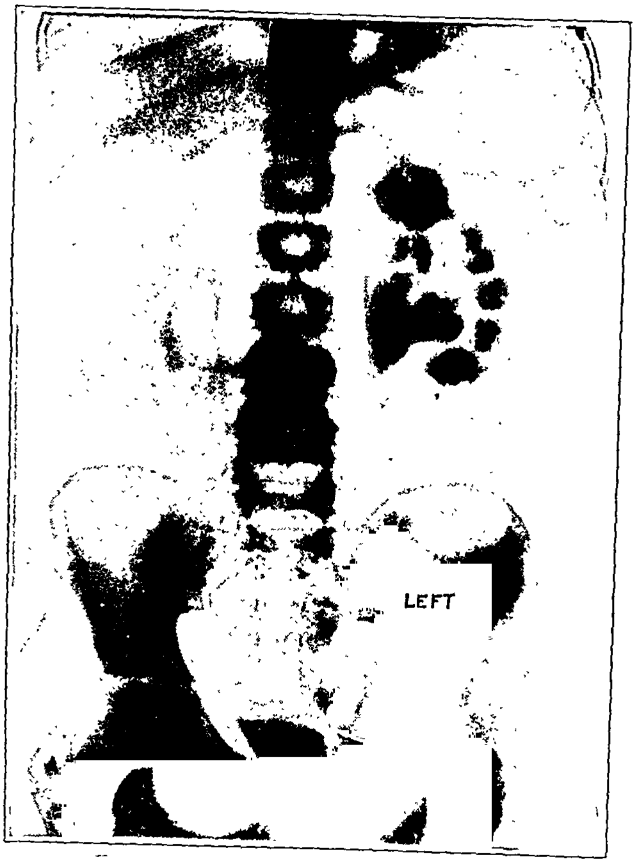

Fig. 6.—Same patient as in figure 5, with bladder partially empty, now demonstrating stricture (congenital) ureterovesical junction with marked dilatation of lower part of ureter, which was hidden on previous film by distended bladder. (Case of Drs. Leopold and Stewart of the Lenox Hill Hospital, New York.)

Finally, in order to establish the percentage excretion of the iodine and of the precipitated acid, it is necessary to determine the actual amount of injected salt in terms of the iodine component, and also in terms of the precipitated acid. It is obvious that, in the preparation of the solution, losses will occur. The following are the factors and sources of error which should be considered:

1. Apothecary scale used—about 2 per cent.
2. Loss due to the moisture content of the salt—about 3 per cent.
3. Loss through double filtration of the solution—about 3 per cent.
4. An indeterminate loss due to the impossibility of a quantitative transfer of the 40 per cent solution from the glassware used in its preparation.
5. The difference in molecular weight of the sodium salt (301) and the precipitated acid (279), 7 per cent.
6. Loss due *to the solubility* of the precipitated acid, a fraction of 1 per cent.

Thus, to establish the extent of inaccuracy in the quantity of iodine actually administered as against its theoretical content, a solution as for injection was prepared. Its actual iodine content, determined chemically, was found to be on the average 89 per cent of the theoretical. This figure can be designated as "the iodine factor."

The method for establishing the "precipitated acid factor" was similar to the foregoing except that the prepared solution was then distributed among normal urines so that each two hour specimen resembled approximately in its volume and substance content those excreted by patients injected with different amounts of the solution of the sodium salt. (In carrying out the renal function test by means of the quantitative estimation of the excreted substance, five or six two-hour urine specimens are collected.) Table 4 demonstrates the average established factor; namely, from 77 to 78 per cent.

Table 4.—*Corrected Acid Substance: Factor for Calculating Percentage of Excretion*

	Druggist Scale	Chemical Scale	Per Cent of Loss
1.	40 Gm. of substance..............	39.525 Gm.	(—) 1.19%
2.	Drying	38.2 Gm.	(—) 3.35%
3.		....	(—) 2.95%

4. Aliquot for iodine determination, 4 cc. of total 96 cc.
5. Distribution on basis of average urinary output by volume and by weight

Specimen	Volume, Cc.	Containing Approximately	Gm. Precipitated Acid Recovered
A. 2 hrs.	550	1/2 solution precipitated and filtered	16.95
B. 2 hrs.	175	1/4 solution precipitated and filtered	8.19
C. 2 hrs.	150	1/10 solution precipitated and filtered	3.515
D. 2 hrs.	90	1/20 solution precipitated and filtered	1.555
			29.850
Aliquot 4 cc.			1.24
			31.090

Acid substance factor (apothecary scale), $\frac{31.09}{40.0} = 77.7\%$

Acid substance factor (chemical scale), $\frac{31.09}{39.525} = 78.66\%$

This factor is variable within narrow limits depending on points enumerated

In other words, to establish the basic acid value, *22 per cent is to be* deducted from the theoretically administered weight of sodium salt when calculating the percentage of excretion in terms of acid substance. Similarly, *11* per cent is to be deducted from the theoretical iodine content of the injected sodium salt in order to estimate the percentage excretion in terms of the iodine component.

These aspects being clarified, it now becomes evident that quantitative determinations of the excreted substance in terms of the precipitated acid can form the basis of a test for renal function. (The quantitative estimation of the precipitated acid has been chosen in preference to that of the iodine because of its relative simplicity and reliability.) Normally about 85 to 95 per cent of the substance can be recovered from the urine within from eight to twelve hours after the injection. In two cases 98 per cent was recovered. From that period on, under normal conditions, as a result of the solubility of the precipitate, which during this stage occurs in such small amounts, its presence can be detected only by an iodine determination method. It is thus found that the excretion of very small amounts of the substance goes on from three to ten and perhaps more days after the injection. For example:

First twenty-four hours, 850 cc., 0.3195 Gm. of iodine.
Second twenty-four hours, 1,200 cc., 0.0218 Gm. of iodine.
Third twenty-four hours, 1,400 cc., 0.0036 Gm. of iodine.
Fourth twenty-four hours, 1,400 cc., none.

From the results already obtained, it is seen that the normally functioning kidney possesses the ability to excrete this substance in a relatively large quantity within a given short period. This may be characterized as "the thrust excretion ability of the normally functioning kidney," present during the first two hours. To illustrate, from about 45 to 65 per cent of the total precipitable acid is recovered during the first two hours, about 20 to 33 per cent during the next two, and the remainder during the subsequent hours. Figure 3 illustrates the curves of excretion in a normally functioning and in a poorly functioning kidney.

Aside from the dose administered and the extrarenal factors influencing renal secretion, the thrust excretion ability of the normally functioning kidney plays a vital rôle in determining good roentgenologic visualization. During the later periods, in spite of the fact that the substance is still being excreted, poor or no visualization is obtained. Good visualization is dependent on a definite concentration of the shadow-producing element determined by the factors enumerated. When the additional mechanism of obstruction is present, visualization may be had although the normal height of excretion is absent, provided excretion takes place. On the other hand, under the same circumstances but with normal excretion, intensification of the shadow results. Thus, in a general way, it may be said that visualization, poor visualization, or no visualization is dependent on the functional activity of the kidney, in other words, its concentrating ability, as well as on extrarenal factors.

However, of the 122 cases studied at the Mount Sinai Hospital, one unexplainable exception has been noted. A woman, aged 54, with pain in the back and left kidney region, had an intravenous urogram done, June 2, 1930. Visualization was absent on the right side in all plates. The left urinary tract appeared normal. A large shadow of what looked like kidney was seen in the right upper quadrant. A faint curvilinear shadow in the bony pelvis on the right side was also observed (ureter?). June 4, cystoscopy and a right retrograde pyelogram revealed normal indigo carmine from both sides as well as the presence of a right sacral kidney. In order to gain an insight into this discrepancy, another intravenous urogram was repeated about two and one-half weeks later. The right kidney pelvis again was not visualized though the ureter could be definitely seen. This example serves to illustrate the need for caution in passing final judgment with absolute certainty on the functional state of the kidney by this method alone.

Moreover, it is also important to bear in mind that the functional activity of the kidney may be temporarily or permanently inhibited, and that the mere nonvisualization at a given examination does not necessarily signify permanent renal damage. The following case is illustrative:

Cystoscopic examination of a man, aged 41, was done, and a left retrograde pyelogram was made. At that examination normal indigo carmine excretion from both ureters was observed. The left pyelogram was normal. Following this examination, hematuria and marked pain in the left loin set in and persisted for about one week. When both symptoms had subsided, intravenous urography was done. Absent visualization of the pelvis and ureter with good kidney outline on the left side and a double pelvis and forked ureter on the right were noted. However, another intravenous urographic examination, about three months later, revealed a normally functioning and appearing left urinary tract in addition to the previous observations on the right; in other words, a case of temporary functional inhibition following retrograde pyelography.

Therefore, to evaluate intravenous urography and to interpret correctly the results obtained from it, it is of paramount importance to consider this method as an excretory one and to bear constantly in mind the processes occurring in the renal and extrarenal systems.

As an adjuvant in assisting one to interpret and to evaluate the radiologic results, it is felt that simultaneous determinations of the substance recovered in the urine as described are sometimes helpful. It is not assumed that this test is superior to other tests of renal function; but, in view of its relative simplicity and the fact that it forms part of the intravenous examination, its use is advocated solely as a confirmatory aid in the interpretation of the intravenous urogram.

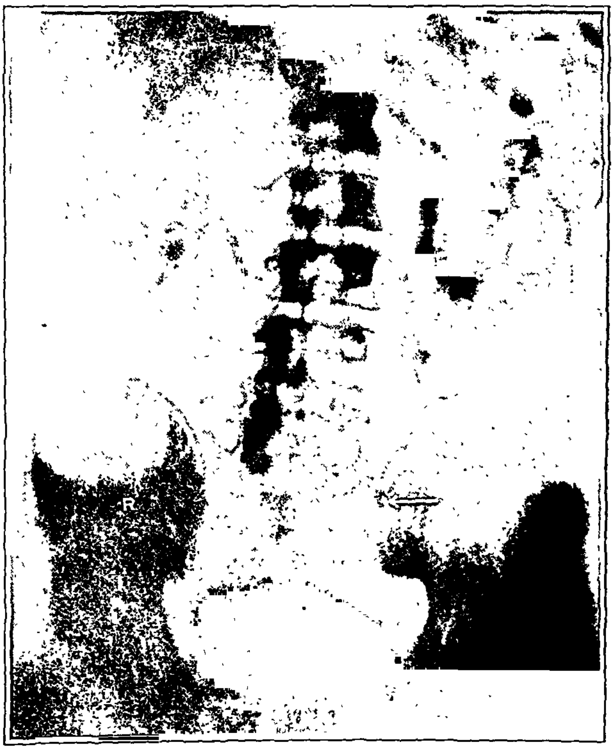

Fig. 7.—Impassable stone obstruction, lower third of the left ureter, in a boy, aged 19. Intravenous urogram—good function—showing dilated ureter, pelvis and calices above stone. Right side normal. 50 Gm. of substance. Arrow points to stone.

The blood urea, phenolsulphonphthalein, the indigo carmine, and the dilution and concentration tests are of great assistance in establishing the contraindication to the application of this method in a given case of bilateral advanced kidney disease. Where the blood urea is high and the concentrating power of the kidney poor, the method yields few anatomic data and becomes not only superfluous but perhaps attended by danger. For information of renal function under such circumstances, more simple and less expensive means, such as the blood urea and phenolsulphonphthalein determinations, serve the purpose.

In addition to anatomic data derived by this physiologic procedure, another vitally important phase of the urinary tract that can be studied without the introduction of instruments is the functional dynamic activity of the pelvis, ureter and bladder.

METHOD OF ADMINISTRATION

For an adult, the usual dose, 40 Gm. of substance, is added in small quantities to doubly distilled water, which has been previously warmed to a moderate degree so that the resultant volume is about 100 cc. Stirring aids the process of dissolving. The solution is filtered twice through ordinary filter paper into a 250 cc. clean Erlenmeyer flask, which is preferably stoppered with fresh wax paper. It is then sterilized in a water bath for half an hour or autoclaved at 15 pounds pressure for twenty-five minutes. The syringe method, in preference to that of the gravity, is chosen, in the feeling that it is more apt to avoid the possibility of a foreign body reaction. A sufficient number of record syringes plus injection needles is sterilized in distilled water. The injection is done in two or three stages at intervals of from three to five minutes. The first roentgenogram is usually taken about fifteen or twenty minutes after the last injection. The subsequent three plates are made about twenty-five minutes apart. When functional disturbances are present, it is advisable to have additional later plates, at approximately one to three hour intervals, taken to determine definitely the absence of visualization, or the presence of late visualization. Particularly in those cases in which there is the added factor of obstruction—ureteral stone, prostatic enlargement, or ureteral strictures—there may be a late, but good or poor type of visualization. Experience alone will guide one in the interpretation of the plates, as well as the number of plates that may be necessary.

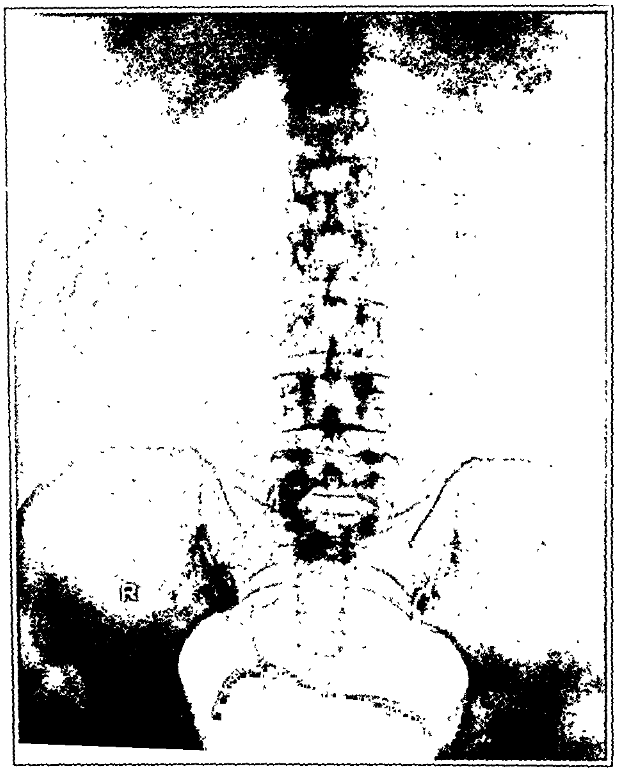

Fig. 9.—Intravenous urogram of a woman, aged 45, showing nonfunctioning sacculated right kidney, proved at operation to be a tuberculous pyonephrosis. Retrograde pyelogram impossible. Ureter could not be entered. Left side normal. 40 Gm. of substance.

An added factor of great importance which has improved the results as far as density, clarity and consistency of shadow are concerned has been the application of a moderate degree of compression by means of an air-inflated rubber balloon (basket ball bladder), maintained over the urinary bladder region for from five to ten minutes prior to and during the taking of each roentgenogram. It is also advisable to take one or two plates without compression several minutes after any of the preceding ones and to have the patient empty his bladder after the second or third plate.

From studies controlled on the same patient with different doses several days apart, the impression gathered is that the administration of a 50 to 60 Gm. dose of substance in 40 per cent concentration, given in divided portions at about a ten minute interval, yields denser and clearer roentgenograms. However, in view of the fact that this increased dosage means additional expense and that with a 40 Gm. dose sufficiently good practical results are usually obtained, particularly with compression, this change is at present advocated with some reserve. A 20 Gm. dose in adults has also given positive results.

The doses (40 per cent concentration) for children are as follows: 13 years of age, from 25 to 30 Gm.; 9 years and up, 25 Gm.; 6 years and up, 20 Gm.; 4 years and up, 16 Gm.; 2 years, 14 Gm.; 6 months, from 10 to 12 Gm.

REACTIONS

During the injection the patients experience transient thirst and generalized warmth, particularly involving the face and bladder regions. Nausea and vomiting of transient duration have occurred twice. Occasionally there is pain up the arm of injection, which, however, disappears shortly afterward. Paravenous infiltration produces pain but no necrosis. Thrombosis at the site of the injection has not been observed. The urine does not reveal any evidence of renal damage by the substance.

APPLICATION

The field of application of intravenous urography is evident whenever cystoscopy, ureteral catheterization or retrograde pyelography is dangerous or impossible for infectious or mechanical reasons, and whenever these procedures in general are indicated. The method, aside from offering a bilateral urogram, is also helpful in the presence of hematuria, in cases of implanted ureters, in children, and in individuals in whom instrumentation is taxing and harmful.

CONTRAINDICATIONS

Patients with uremia or latent uremia, as determined by the usual clinical methods, do not lend themselves to the application of this method. It is therefore wise to precede the examination by a determination of the blood urea. Experience with hyperthyroid patients is still wanting. The drug in cases of pulmonary tuberculosis does not seem to have any deleterious effect.

For pyeloscopic purposes this method will be feasible only when the density of the excreted substance is sufficiently great. When the function is poor, pyeloscopic results will be correspondingly deficient.

In my original paper published in the *Klinische Wochenschrift* in November, 1929, I[11] stated that the iodine component could not be demonstrated in the circulating blood. In the report by Heckenbach[15] from von Lichtenberg's clinic, Tourné and Damm have shown this to be incorrect. Studies which I was making at the time confirmed their observations. I could detect its presence in the blood as late as ten hours after a 50 Gm. dose. The stools and sputum of the patients injected show the presence of the iodine component in relatively small amounts. In the stool this element could be detected in a bowel movement as late as three to four days. It is also of interest to note that the skin of rabbits injected intravenously with a solution of the substance contained the iodine component.

INTRAVENOUS UROGRAPHY (SWICK METHOD)*

LEOPOLD JACHES, M.D.
Radiologist, Mount Sinai Hospital; Consulting Radiologist, Montefiore Hospital
NEW YORK

The history of the development of this method as well as the chemical and pharmacologic properties of the substance employed are dealt with in greater detail in the paper by Dr. Swick presented before the Section on Urology.

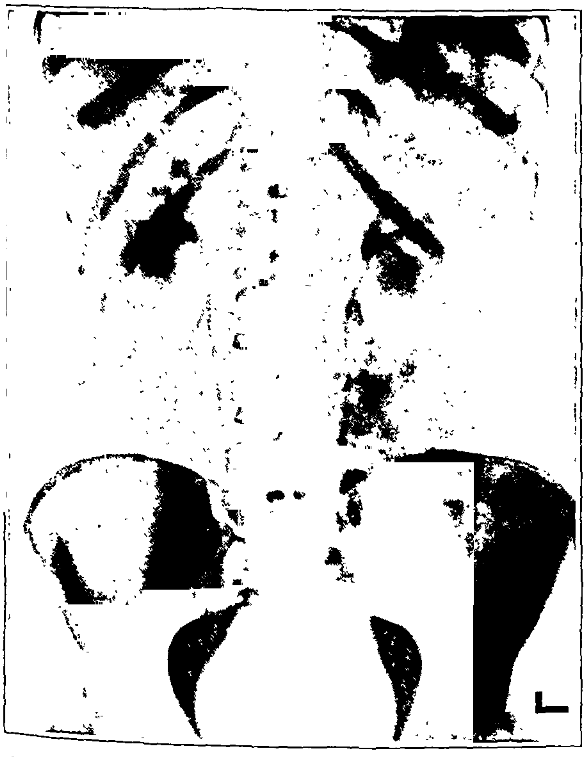

Fig. 1.—Normal urogram of an adult; 60 Gm. of substance injected.

Swick states that the present substance, prepared by Professors Binz and Räth, is nontoxic, very soluble in water, neutral in reaction and under normal conditions excreted as such through the urinary tract within eight to twelve hours to the extent of from 85 to 95 per cent. Iodism has never been observed. Its tolerance is exceedingly great. From about 45 to 65 per cent of the substance is normally excreted during the first two hours. For this reason, the urograms show their greatest intensity during this period.

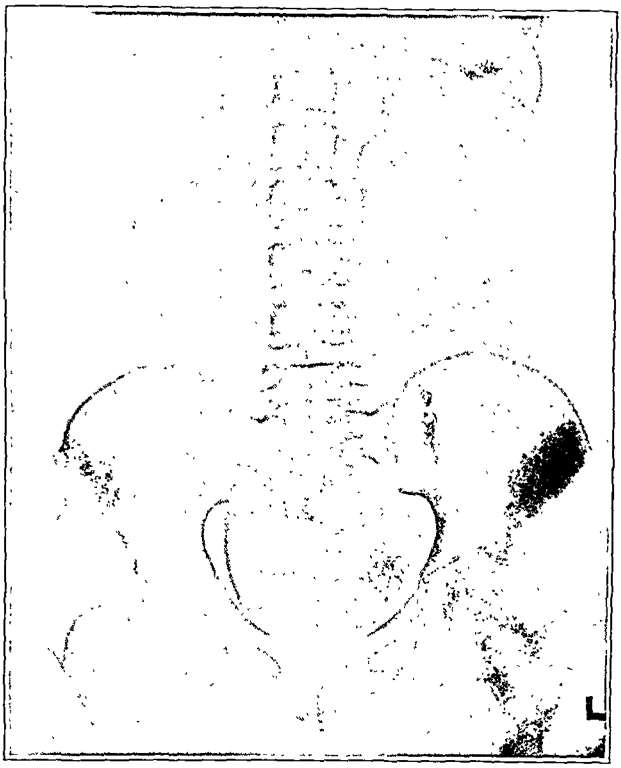

Fig. 2.—Normal urogram of patient, aged 13½ years; 30 Gm. of substance injected.

The technic of administration is as follows: A 40 per cent solution is made up in doubly distilled water to a volume of 100 cc., filtered and then sterilized. Injection is done by means of several record hand syringes into the veins of the arm. The quantity administered is, for an adult, from 40 to 60 Gm. of the substance in a 40 per cent concentration. Younger persons receive proportionate doses. For children aged from 6 to 9 months the dose is 10 or 12 Gm. of the substance; up to 2 years, 14 Gm.; 4 years and up, 16 Gm.; 7 years and up, 20 Gm.; from 10 to 13 years, 25 Gm., and 13 years old and up, 30 Gm. It was found roentgenologically that the injection in adults of from 50 to 60 Gm. of substance yields the better shadows. If 60 Gm. of substance is used, the full quantity of the solution may be injected continuously, or half is injected first and then the other half ten or fifteen minutes later. The shadows obtained then are nearly, though not quite, as dense as those by the retrograde or cystoscopic method. During the injection the patient has an evanescent sensation of thirst and warmth; occasionally in the injected arm pain is experienced during the injection. I have observed no other reaction.

The roentgen technic is that usually employed in urinary tract examinations: the Potter-Bucky diaphragm, a 14 by 17 film (occasionally a smaller size if only part of the tract is wanted), and compression by means of the rubber bag. The patient is kept on the table for at least one hour after the injection. The best roentgenologic results are obtained fifteen, thirty-five and sixty minutes after the last injection. After that period good outlines are obtained only in cases of delayed renal function, combined with obstructive lesions. It is therefore important to have each film developed immediately in order to determine for how long a period the taking of roentgenograms should be continued. It may sometimes be necessary to take roentgenograms at one to three hour intervals until good shadows are obtained. Sometimes it is necessary to have the patient empty the bladder in order better to demonstrate the lower ends of the ureters.

[*] From the radiologic and urologic services of the Mount Sinai Hospital.

[*] This article is abbreviated in The Journal by the omission of six illustrations, which will be found in the author's reprints.

[*] Read before the Section on Radiology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

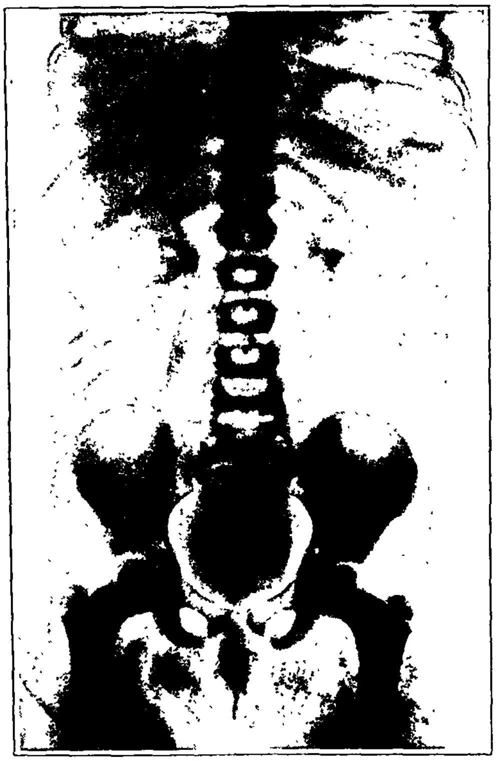

Fig. 3.—Right-sided pyelo-ureteritis in girl, aged 5½ years; 16 Gm. of substance injected.

The intravenous method is indicated in all instances in which urography is desirable and is applicable in many more cases than the retrograde method, because the objections to instrumentation are eliminated. It has thus been possible to employ this method in children as young as 6 months and in adults with large prostates, cardiac disease or other contraindications.

Contraindications to the use of the intravenous method would be actual or latent uremia in which, as a result of the poor concentrating power of the kidney, meager or no anatomic information could be obtained. For functional data, much simpler and less expensive methods, such as the blood urea determination, the phenolsulphonphthalein, indigo carmine, and the dilution and concentration tests can be applied. In addition, the procedure might prove dangerous. Therefore, it is strongly advocated by Swick that patients about to be subjected to the intravenous procedure should have at least a blood urea, phenolsulphonphthalein and concentration tests performed. The intravenous method, however, does not eliminate the retrograde or cystoscopic method; this is especially true in cases in which kidney function is impaired and therefore the iodine concentration is so poor that the tract is not sufficiently visualized. Here the retrograde method has to be resorted to in order to obtain an anatomic outline of the renal pelvis and ureter. The bladder will generally be shown well, unless both kidneys are below par. The faintest shadows are obtained with poorly functioning kidneys, the densest when obstruction is present. The roentgenographic contrast is heightened by means of the compression bag, which should be kept on for from five to ten minutes prior to and during the taking of the roentgenograms. One or more after each of these might also be taken without compression.

The advantages of the intravenous method are manifold. It intensifies the kidney shadows, frequently bringing out irregularities in outline. Instrumentation is avoided which even under favorable circumstances is, to say the least, very unpleasant and which, as will be seen from some of the illustrations, seems to cause a temporary inhibition of function of the kidney subjected to it. The entire urinary tract, including the bladder, is shown at one application of the method. With the cystoscopic method it has generally been found necessary to inject each side at separate sessions so as to avoid the severe reactions that frequently followed bilateral pyelography performed at one session. For the same reason the intravenous method is safer in cases of solitary kidney. Anomalies in the urinary tract, such as double ureters, are revealed in some cases in which the cystoscopic method failed for technical reasons. It is not subject to failure in stricture of the ureter and is the only useful method in the study of the result of transplantation of ureters. It eliminates the artefacts which not infrequently complicate the other method and sometimes make one hesitate to designate a transparency within the opaque material as a calculus

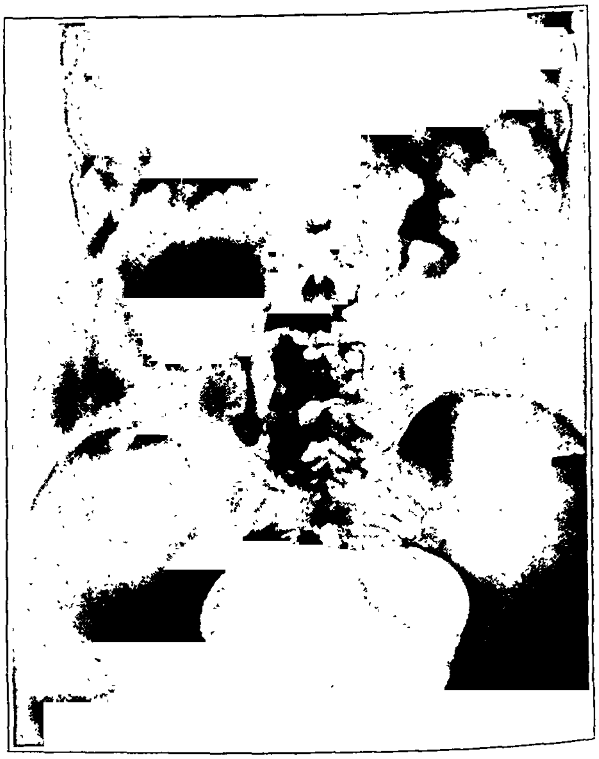

Fig. 4.—Right nephropexy in woman, aged 31; 40 Gm. of substance injected; distortion due to operation; depression in left upper quadrant of bladder is due to the uterus.

rather than an air bubble or to say that a defective calix is due to a pathologic lesion and not to poor injection technic, especially when the urologist happened to be one of limited experience.

An added advantage of this method is that it demonstrates not only the anatomy of the urinary tract but also its function. The roentgenographic determination of function is, however, not sufficient in itself; according to Swick it should be supplemented by the quantitative determination of the excreted substance, which can be recovered from the urine. It will undoubtedly also give information regarding peristalsis of the ureters and the physiology of the pelvis and calices. In some cases of renal calculus, spasm of the calices was shown, probably as a reaction to the presence of the foreign body. In others in which the retrograde method preceded the intravenous, temporary nonvisualization on that side was present. It is important, therefore, to remember that the mere nonvisualization at a given examination does not necessarily denote permanent renal damage and therefore it is wiser to use the term functional inhibition.

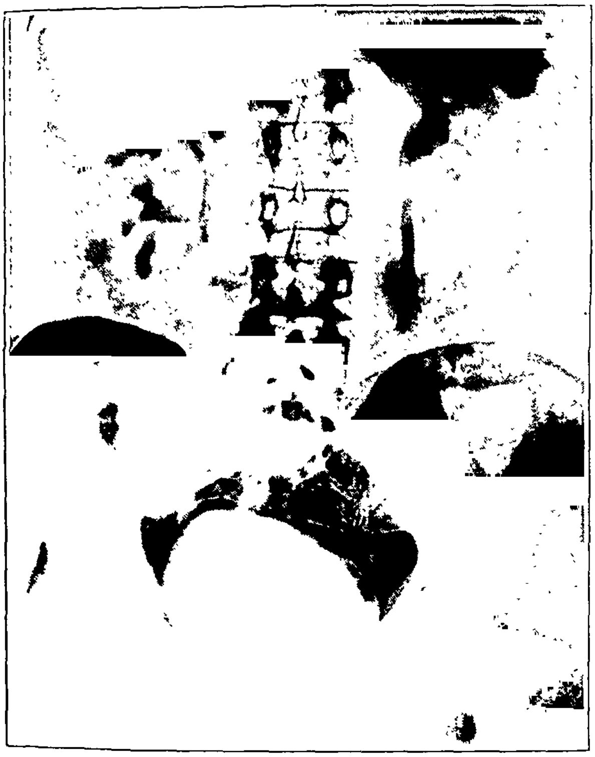

Fig. 5.—Bifid right renal pelvis and forked ureter. One week after a left retrograde pyelogram which was done three months previously, the left side did not visualize at all, and the right side but slightly. Now both sides are well visualized.

One Hundred East Ninety-Fourth Street.

ABSTRACT OF DISCUSSION

Prof. Leopold Lichtwitz, Altona-Elbe, Germany: Pyelography by way of excretion is an old desire. Dr. Rowntree was the first to attempt the visualization of the urinary tract by means of sodium iodide. Professor Binz of Berlin, who for a long time was greatly interested in chemotherapy, invented and prepared with his collaborators the group of selectans. Selectan and selectan neutral were sent by him to the clinic at Altona with the idea of attempting to influence coccus infections. In order to attempt treating infections of the kidney pelvis and gallbladder, we studied the output by the kidney and liver. We obtained evidence that the preparations did not cause iodism. The fact that these selectans are iodine-containing, excretable by the kidneys and liver and cause no iodism, which had been the greatest obstacle in the earlier attempt, naturally led to the idea of testing them for the widely desired intravenous pyelography. Surely the invention of Professor Binz is the one leg of the new method. The second basis is the work of Dr. Swick. Important as is the existence of preparations, they become valuable only when the right person takes them for a special purpose. This is made clear by the fact that the preparations of Professor Binz were tested for the same purpose before Dr. Swick began his studies (without his knowledge) by a man of great experience in research work—without sufficient results. Between the important work of chemical preparation and final success, there came the hard work of a clever and energetic man, one with the deepest devotion to and greatest passion for research work. Therefore, we appreciate the work of both Professor Binz and Dr. Swick, and as this work is based on the invention of a famous German chemist and the investigations of a young American working in Germany, it may be considered as another hopeful symptom of scientific cooperation and friendship between our two countries.

Prof. Arthur Binz, Berlin, Germany: It was my idea in 1921 to attach arsenic or other elements such as iodine to heterocyclic nuclei, such as those of the alkaloid group, and possibly thereby intensify therapeutic efficiency in the treatment of syphilis. My assistant, Dr. Raeth, and I chose the simplest heterocyclic nucleus, the pyridine, and transformed it into about 700 new arsenic and iodine compounds. Expecting them to be very toxic, we were much surprised to find several of an unheard of tolerability when compared with the known arsenic and iodine compounds. This new biochemical principle, which we ascertained in animal experiments, caused me finally to select sodium-2-oxo-5-iodo-pyridine-N-acetate ("Uroselectan") for intravenous urography. This new relationship between chemical

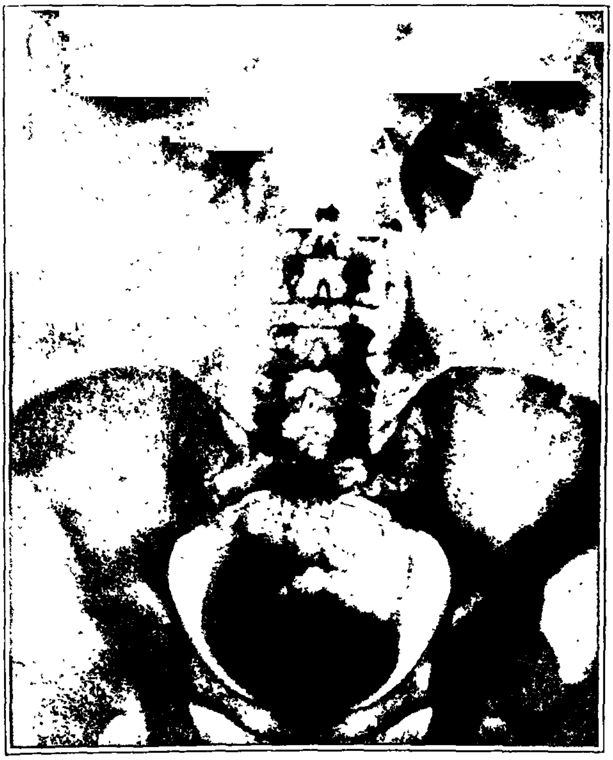

Fig. 6—Papillary carcinoma of urinary bladder extending from the left orifice to the internal sphincter, according to cystoscopic diagnosis, in woman, aged 62; 50 Gm. of substance injected. The left ureteral orifice cannot be seen. There was no indigo carmine excretion from left side; good blue from right. Intravenous pyelogram shows dilatation of left urinary tract, especially of juxtavesical and intravesical portions of the ureter. The denser shadow on the left than on the right normal side is due to partial obstruction at the left ureteral orifice.

structure and biologic action we published in the *Zeitschrift für angewandte Chemie.* Sodium-2-oxo-5-iodo-pyridine-N-acetate, in its present form, was made in 1927, long before Dr. Swick came to Germany. Its selection by me for the purpose of intravenous urography was not due to suggestions of Dr. Swick but was in answer to clinical principles which had been agreed on by Professor von Lichtenberg and me, before Professor von Lichtenberg's trip to America last year. Concerning priority, Hryntschak of Vienna in 1927 was the first to investigate selectan compounds for intravenous urography, including what is now known as sodium-2-oxo-5-iodo-pyridine-N-acetate. Hryntschak obtained but partial success. Professor Lichtwitz of Altona in 1929 in his investigation of the treatment of human infections by selectan neutral, which I had sent him, observed that this compound had another effect which concerned intravenous pyelography. But all these results were clinically negligible. After working with selectan neutral and other selectan compounds, in Professor von Lichtenberg's clinic, and obtaining disappointing results, final success was achieved when I selected sodium-2-oxo-5-iodo-pyridine-N-acetate for use. It was given by me to Dr. Swick, who had been appointed by Professor von Lichtenberg to try out the compounds that I would give him.

Dr. Moses Swick, New York: When I began my studies, as Professor Lichtwitz has pointed out, a substance synthesized by Professors Binz and Räth, having the formula m-methyl-5-iodo-pyridon ("Selectan Neutral") was being tested for coccus infections at his clinic in Altona, Germany. Studies on its excretion, and its iodine content, led to the idea of applying it for roentgenologic purposes. The encouraging results pointed to the possibilities of further development. Following a dose of 6 Gm. (one third of the calculated maximal dose), certain disturbing symptoms resulted. Some were headache, nausea, vomiting and general discomfort. Of particular interest was the occurrence of transient diplopia in two cases. This suggested the possibility of the methyl radical being the toxic factor. My experience with this substance brought out the need for a modification, possessing better tolerance, greater solubility, and a higher iodine content, so that a larger dose could be administered and a higher concentration of the excreted iodine component be obtained. This work had been carried out at the clinic of Professor Lichtwitz for seven months before conferences were held with Professor Binz. The full data concerning these conferences and other matters here discussed will be presented by me tomorrow before the Section on Urology. As a result of my first presentation of the needs to Professor Binz, he furnished me with a compound, which, because of its insolubility, had to be administered by mouth and gave no results. At the second conference, in which Professor Lichtwitz participated, the whole ground was gone over again. Professor Binz felt confident that our needs could be fulfilled. Thereafter I continued the investigations in the clinic of Professor von Lichtenberg. There again I tested "Selectan Neutral," the second substance, and a third furnished by Professor Binz, which also had to be given by mouth and was unsuccessful. Finally, Professor Binz gave me a substance of the selectan group, which had a sodium acetate radical substituted for the methyl (sodium-2-oxo-5-iodo-pyridine-N-acetate). This compound fulfilled the needs, and satisfactory urograms could now be obtained. Professor von Lichtenberg, who was in the United States at the time, was promptly informed of the results. These were reported by me in detail at the Urologic Congress in Munich in September, 1929. I am not a chemist but have interested myself along the chemical lines required by the theoretical side of my problem and the chemical examinations needed in the course of the clinical investigations.

Dr. Theodore Sokow, Kenosha, Wis.: The use of this new method necessitates changing one's conception in explaining and diagnosing roentgenograms. With the cystoscopic method, a forcibly dilated kidney pelvis is obtained, not corresponding to the anatomic conditions. With the intravenous method, the physiologic dynamic conditions of the kidney and ureters are observed. That explains why pictures taken at the moment of the kidney contraction may show the pelvis very small and the calices not at all. Only in the diastole is a perfect picture obtained Certain technical procedures may improve the results, as elevation of the pelvis of the patient and compression of the region of the lower ureters. In one of the latest articles, Dr. Hryntschak of Vienna is recommending the use of solution of pituitary to increase the concentration of the dye in the kidney and atropine to delay the excretion of the dye. It seems worth while to try these and other drugs for the same purpose. In my experience, sodium-2-oxo-5-iodo-pyridine-N-acetate has given very good results and few after-effects. About two months ago, at the annual convention of the German Roentgen Society in Berlin, different authors mentioned a new product, produced by another chemical concern in Germany. I was able to secure lately a small amount of this chemical, and used it in different cases with very satisfying results.

Dr. L. T. Le Wald, New York: Dr. Jaches has brought out two or three uses that seem to me very important. As I have had one case of implantation of both ureters into the sigmoid, similar to his case, and as I know of several cases at the Mayo Clinic, I would be interested to learn whether the rest of these cases could be examined and see whether dilatation of the ureters has occurred in the other cases in which there was exstrophy of the bladder. The second point relates to the possibility of misinterpretation, because one kidney didn't show function temporarily which might lead one into error. Dr. Jaches, however, has emphasized the fact that either repeating the test or roentgenographing the patient at a little later time shows that the kidney did function, thus avoiding erroneously diagnosing a single kidney because of this possibility of spasm interrupting the secretion. And then in case of horseshoe kidney, I think it is exceedingly valuable. Occasionally in a thin subject, at least in one case, I was able to see the shadow of the kidney going across the median line, but as a rule one would be in doubt in a case of that sort. In Dr. Jaches' case, the shadow was certainly very conclusive after the use of sodium-2-oxo-5-iodo-pyridine-N-acetate. I would like to ask Dr. Jaches if any alarming reactions have occurred. A urologist in New York told me that in his first case in which the injection was given through rubber tubing he had had some reaction and he did not give more than half the dose and then desisted from finishing the examination, saying that the patient had some dizziness and collapse, and he didn't feel safe in going on. I wish Dr. Jaches would say a word or two more about technic.

Dr. B. R. Kirklin, Rochester, Minn.: You might be interested to know of a little Scotch trick that we have employed at the Mayo Clinic. Dr. Braasch and his associates have been collecting the urine of the patients after they have received sodium-2-oxo-5-iodo-pyridine-N-acetate and sending it to the chemist, who has been able to recover approximately 65 per cent of the amount originally injected. I am informed by the chemist that the substance recovered in this way is a purer product than the original drug.

Dr. Leopold Jaches, New York: In 122 cases there have been no unpleasant reactions. What was the cause of the reaction in the case quoted by Dr. Le Wald, I do not know. It may be that this patient was an unsuitable subject. I suggest that this case be reported with all clinical data, so that more can be learned about all possible contraindications than is known today. I am glad to hear from Dr. Kirklin that at the Mayo Clinic the material was used over again. Dr. Swick has proposed the same thing to me but as yet I have not followed his suggestion. I made up my mind to keep out of the controversy regarding the origin of this matter. I would like, however, to say in connection with what has been stated concerning Dr. Hryntschak that a real practical success did not result from his studies. As Dr. Swick is much more familiar with this phase of the subject, he should be permitted to discuss it for me.

Dr. Moses Swick, New York: At the Urologic Congress in Munich in 1929, where I presented my paper, Dr. Hryntschak was present. He did not discuss the subject but in his article which appeared at that time in the *Zeitschrift für Urologie* in 1929 he said on page 904 that although he had succeeded two and one-half years before in obtaining useful pyelograms in a few cases, the method had by no means met the conditions set forth by him. He, however, expressed the hope of accomplishing his aims by continued investigations. I might add that he gave neither the name nor the chemical formula of any of the substances employed, but he mentioned three of them by number as 12, 27 and 48.

MALIGNANT CHORIONEPITHELIOMA UTERI *

HENRY SCHMITZ, M.D.
AND
WILHELM HUEPER, M.D.
CHICAGO

Tumors of the chorion have interested the profession for many years. Saenger[1] in 1888 described the symptoms and diagnosis, and Fränkel[2] and Marchand[3] in 1895 demonstrated that the chorionic epithelium gave rise to these growths. In 1910 Ewing[4] published his investigations on the prognosis of these growths based on a histologic study.

The difficulties of making a clinical and pathologic diagnosis of the diseases and the tumors of the chorion are great. The fact that under normal conditions syncytial wander cells are found in the decidua and the myometrium, and that some of the choriomas are composed of all the elements and others of only the epithelial cell elements of the trophoblast, are responsible for the difficulties in diagnosis.

Six cases of malignant chorionepitheliomas were observed in our clinic within a relatively short time. They were referred on account of severe uterine bleedings, while one case was referred for diagnosis (case 2). The pathologic, diagnostic and therapeutic observations made in these cases are herewith recorded.

Malignant chorionepithelioma is a tumor originating in the epithelium of the chorionic villi. Hence it occurs only in association with pregnancy and therefore appears during the child-bearing period of a woman's life. The new growth is always located in the genital tract, namely, the uterus, the uterine tubes, the ovaries or the abdomen, depending on intra-uterine, tubal, ovarian or abdominal pregnancy. Malignant chorionepithelioma develops from fetal instead of from maternal tissues, often in the earliest stages of pregnancy, and ultimately destroys the mother's life.

A diagnosis of malignant chorionepithelioma must be made when solid masses of syncytial and Langhans cells are found side by side with destruction of uterine tissues, invasion and erosion of blood vessels, and presence of extensive necrotic masses, pointing to rapid proliferation of tumor cells. The growth does not possess a stroma or a blood supply of its own.

Chorionepitheliomas may be typical, transitional and atypical. They may be primary or follow a simple or an invasive hydatid mole or placental polyp. Chorionic cells in the form of large syncytial wander cells may be found in the maternal tissues during the entire course of normal pregnancy. The trophoblast possesses all the cell elements, and even the invasive and destructive powers characteristic of malignant growths though they are entirely physiologic in nature.[5] It is obvious that the differential diagnosis of these diseases and conditions is perplexing and should rest on the pathologic and clinical observations.[6]

The pathology of these various lesions can be best studied by comparing the latter with the structure and maternal relations of the trophoblast. The primitive trophoblast is composed of all the elements of the chorionic villus; namely, syncytium, Langhans cells and a connective tissue core. The syncytium forms the thick outer layer. It contains many vacuoles which give it a spongy and reticulated appearance. The layer of Langhans cells is located beneath the syncytial cell layer. The connective tissue forms the central core. Uncoagulated blood derived from the maternal blood is contained in the vacuoles. Capillaries or blood vessels are not seen. Syncytial wander cells invade the underlying decidua during the entire period of pregnancy. The zone of the decidua adjacent to the blastocyst becomes destroyed and degenerated as the result of the invasive and destructive power inherent in the blastocyst and ascribed to the Langhans cells. The latter show an enormous proliferation and active mitosis which breaks up the maternal blood vessels, the decidua and the uterine glands until the young villi become attached to the maternal tissue, when the invasive and destructive activities of the fetal trophoblast cease. At the site of contact of the fetal and maternal tissue elements a fibrinous layer, Nitabuch's membrane, becomes interposed. It is an expression of a reaction of the maternal structures against fetal invasion.

The simple hydatid mole, also, contains all the elements of the chorionic villus. It probably appears during the earliest stages of chorionic development. The syncytium participates actively in the proliferation with the formation of many vacuoles. The layer of Langhans cells remains rather inactive and may be scarcely discernible. The connective tissue core is always present, though regression may be seen. Absence of this mesodermic layer means degeneration into a chorionepithelioma. The vacuoles form vascular lacunae. Fetal capillaries are absent. Mucous edema of the villi causes formation of vesicles, which have given the growth its name. A simple mole is never invasive and lacks the powers of destruction and metastasis. It usually terminates suddenly by becoming detached from the maternal structures and being expelled in toto. Where the mole comes in contact with the maternal tissue a fibrinous layer is interposed with a zone of plasma and round cells, leukocytes and fibroblasts.

The invasive hydatid mole, termed chorionadenoma destruens by Ewing, possesses all the characteristics of the simple mole. However, the molar villi dip down into the maternal tissues in continuity, causing destruction and cleavages in the uterine wall. Epithelial cell metastases are never seen locally or distantly. The cells possess only limited capacity for independent growth. Proliferation of the molar villi into the uterine blood vessels is marked without the occurrence of any destruction of vessel walls or invasion of the adjacent tissue. The invading villi are enclosed in a true leukocytic limiting wall with plasma cells and fibroblasts. Syncytial cells are not seen outside this fibrinous layer. Detachment of the mole from the maternal tissue and expulsion in toto are often seen. The growth is absolutely benign in its histologic character, as autonomous growth of cells has not been observed.

The typical malignant chorionepithelioma is composed of both epithelial cell elements of the chorion. They assume embryologic morphologic characters and biologic activities. The cells form masses and columns with marked vacuolation and necrosis. One or the other cell type may predominate. The connective tissue core disappears entirely as a result of the proliferating activities of the epithelium. Mucous degeneration in the epithelial cells leads to the formation of vesicles. Fetal capillaries are absent. Syncytial wander cells are often seen in the maternal tissue.

The syncytial and Langhans cells are in active proliferation, have many mitotic figures and show marked anaplasia. The highest potential malignancy seems to be conferred by the presence and activity of Langhans cells. There is invasion by active penetration of the vascular sinuses and destruction of the adjacent tissue. Metastasis takes place by emboli in blood vessels locally and distantly. The growths and metastatic foci cause the formation of a zone of reaction of the maternal tissues against the invasive malignant cells. It is composed of round and plasma cells, leukocytes and fibroblasts.

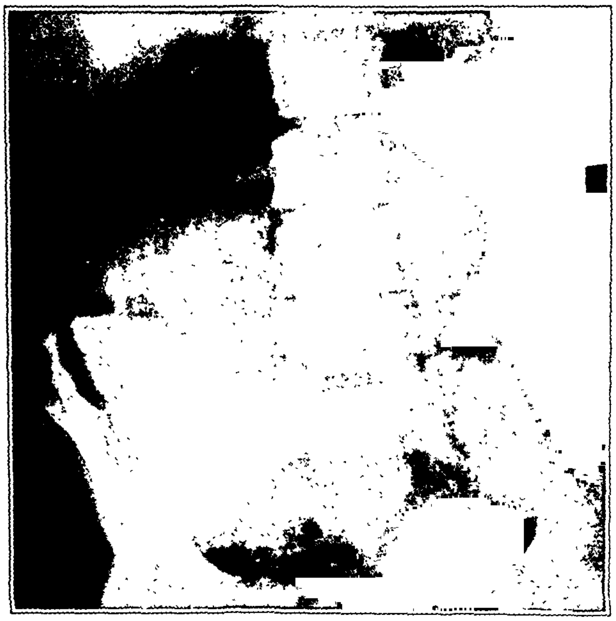

Fig. 1 (case 8).—Appearance of pelvis showing fetus in transverse position and an irregularity in uterine wall at upper right side.

A malignant chorionepithelioma never regresses and rapidly destroys the life of the host.

The atypical chorionepithelioma, or malignant syncytioma of Ewing, is composed only of syncytial cells which assume all the characters observed in the typical chorionepithelioma. The syncytial cells show autonomous growth, anaplasia and abnormal mitotic action with invasion, destruction and metastasis. However, definitely degenerative changes occur early and rapidly and contribute to a relatively benign course.

Ewing describes under the name of syncytial endometritis a condition characterized by the invasion of syncytial cells into the uterine walls. The cells are seen singly but in excessive infiltration. They are ultimate transformations of the syncytium, have reduced vitality, and seldom, if ever, develop a progressive tumor. Active external penetration of vascular sinuses, perivascular invasion from within and local or distant metastases are never seen. There appears to exist a simple hyperplasia of syncytial cells. The condition is benign and regression has been repeatedly observed after a simple curettage. The concomitant inflammatory leukocytic infiltration is a reaction of the maternal tissues to the foreign cells. Many cases of so-called endometritis post partum or abortum probably are instances of these syncytial hyperplasias.

The conclusion may be drawn that the simple and invasive moles are marked by the relative inability of the chorionic epithelium to rid itself from the connective tissue core of the villus to form independent epithelial growths. Hence the persistence of the mesoderm in the chorionic invasion constitutes a reliable index of relative benignancy. Whenever malignant qualifications develop in the chorionic epithelium, as invasion, destruction and capacity for metastases, then the mole ends, and with the disappearance of the connective tissue core the chorionepithelioma begins.

Lutein cysts of the ovary are observed in from 10 to 20 per cent of the diseases and new growths of the chorion. As soon as the mole has been expelled or the chorioma has been removed, the cysts regress as they do after the termination of a normal pregnancy.

Distant metastases occur in lung, vagina, brain, liver, kidney and spleen, arranged in order of frequency. Metastases appear as dark red or reddish brown thrombus-like formations. The color results from old or fresh hemorrhages in the tumor substance.

It is evident from the discussion that histologic examinations should be done on all tissues expelled or curetted after abortions, full term labors, and especially after expulsion of a mole. Microscopic examinations at repeated intervals may be indicated in cases in which suspicious tissues are found or uterine bleeding recurs. Rapid frozen sections from curetted material should be employed in doubtful cases. One should always remember that a negative histologic examination does not exclude the presence of a chorionepithelioma, especially if the growth has an intramural location and is inaccessible to the curet.

Spontaneous regression, according to Ewing,[4] after formation of metastases and incomplete removal, occurs only in the atypical chorionepithelioma and the simple and invasive hydatid moles but never in typical malignant chorionepitheliomas. According to the same author the syncytiomas contribute only 5 per cent to the total number of fatalities from choriomas. In such cases, hemorrhages or secondary infections usually are the direct cause of death.

SYMPTOMATOLOGY

Saenger[1] propounded the following eight factors in the clinical diagnosis: (1) a history of a preceding labor, abortion, or expulsion of a hydatid mole; (2) persistent hemorrhages from the uterus continuing after a curettage; (3) hemorrhagic putrid discharge and secondary infection following intra-uterine instrumentation; (4) progressive enlargement of the uterus; (5) rapidly progressing anemia and cachexia; (6) early metastases especially in the vagina and the lungs; (7) lung involvement which is probably present when dyspnea, cough and bloody expectoration appear, and (8) a rapid course of the disease terminating in death within from six to seven months.

Bimanual palpation reveals the enlarged uterus, often irregular because of the site of growth. The consistency is usually normal but may be soft, especially in unfavorable cases. If the cervical canal remains open after abortion, labor or expulsion of a mole, then a digital exploration of the uterine cavity should be done to determine absence of all tissues from the uterine cavity and the condition of the uterine wall. About 10 per cent of the cases of hydatid mole are followed by a chorionepithelioma. If one is in doubt about the invasive character of the growth after palpation or if an intramural growth exists, a vaginal hysterotomy should be performed. In a recent case of malignant chorionepithelioma the patient gave a history of uterine hemorrhages of about two months' duration and profuse menorrhagias for six months previously. The patient was a nullipara, 35 years of age. On examination the uterus had the size of a twenty weeks' pregnancy and the organ was rather firm in consistency. Fetal quickening was present but fetal heart sounds were not elicited. A roentgenogram of the pelvis revealed a fetus in transverse position in the lower uterine segment. The amniotic sac and placenta occupied an unusually large amount of space. Within twelve hours after admission to the hospital the patient expelled the fetus and membranes spontaneously. Examination of these did not show anything abnormal. The uterus did not undergo any appreciable involution within ten days and a digital examination at this time revealed a growth in the posterior upper wall of the uterus. Examination of a frozen section of tissues removed with the curet showed malignant chorionepithelioma. An abdominal panhysterectomy was immediately performed (figs. 1, 2 and 3). Ponzian[7] used hysterography after the injection of iodized oil to determine the presence of a chorioma in the uterine cavity.

The danger of forcing tumor tissue into the abdominal cavity through the uterine tubes or the weakened uterine wall is great and hence such diagnostic measures should not be recommended.

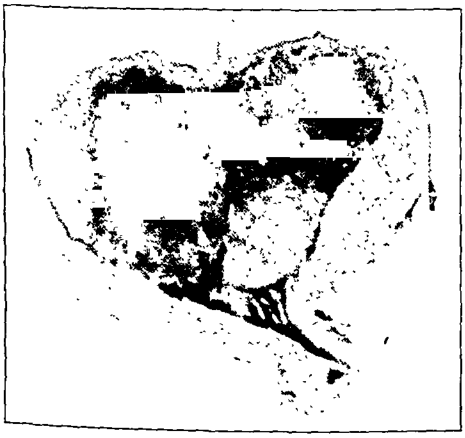

Fig. 2 (case 8).—Typical chorionepithelioma.

Aschheim[8] states that the urine of patients with hydatid moles or chorionepitheliomas gives a pregnancy reaction in mice about twelve times stronger than that obtained from a two months' gestation. The serum of such patients also is not lytic to chorionic epithelium, while serum of normal pregnant mothers is lytic according to Fränkl. Since these biologic tests have been simplified and are easy of execution, it would seem that the reactions are a great aid in the diagnosis of choriomas.

The differential diagnoses comprise: hydatid mole and placental polyps, *either simple or invasive;* endometritis post abortum and post partum; uterine carcinoma and sarcoma; bleeding uterine polyps, and adenomyoma uteri.

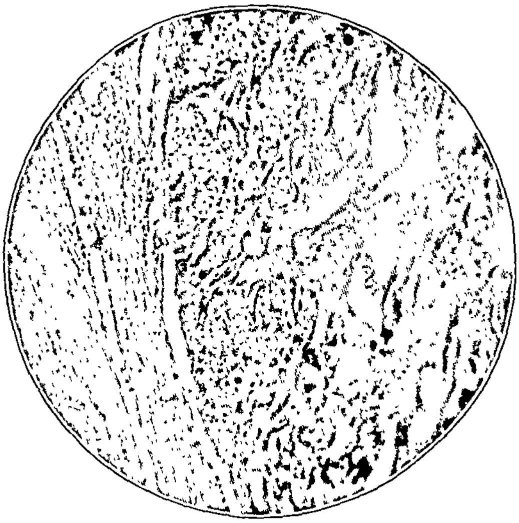

Fig. 3 (case 8).—Typical chorionepithelioma sharply demarcated from myometrium with leukocytic infiltration.

The treatment should be radical if a histologic diagnosis of malignant chorionepithelioma or malignant syncytioma has been made. Even if metastases should be found, hysterectomy may still be done, as regression of metastases has been observed in all choriomas. The syncytial endometritis, if occurring in young women, should be subjected to careful curettage. Should the hemorrhages recur after the curettage, hysterectomy or intra-uterine radium insertions are advisable.[9] Individual problems may present themselves in each case and should be treated accordingly. In general it may be stated that, if conservative measures do not suffice in syncytial endometritis, hysterectomy must be done.

In late years quite a number of cases of malignant choriomas have been reported that were successfully subjected to irradiation.

In 1917 a patient in the sixteenth week of pregnancy entered the clinic on account of severe hemorrhages from the right kidney. A diagnosis of a malignant tumor of unknown type of the right kidney was made. On account of the anemic condition of the patient and the pregnancy, the kidney was treated with filtered x-rays and the hemorrhages ceased. About a month later the uterine contents were suddenly expelled. Microscopic examination revealed a typical malignant chorionepithelioma. Radium was inserted within the uterus and heavy filtered x-rays were applied. The patient is well at the present time. Similar cases have been reported by Naujoks,[10] Gordon,[11] Szathmary,[12]

Liebe,[13] Klein [14] and others. The epithelial tumor cells of choriomas are of a highly embryonic, anaplastic and undifferentiated character and should be very radiosensitive. Therefore radiation therapy should be applied, especially to patients who are poor surgical risks.

In our cases, with one exception, prophylactic radiations were used. This may explain the favorable outcome of the cases. One patient has been well thirteen years and another one two years, after treatment with radium and x-rays. Of five patients surviving operation, four were given x-rays after operation. One has been well for three years, one for two years, one for one year and one for six months. One patient is well one year with operation only. One patient survived the operation only a few days. She was septic when the operation was undertaken. One case of recurrence with brain metastases after hysterectomy was treated unsuccessfully with short wave x-rays. It is generally assumed that absence of recurrence within one year after treatment should be interpreted as an absolute cure.

CONCLUSIONS

1. All tissues expelled during an abortion, a full term labor or an expulsion of a mole should be examined microscopically to exclude disease or new growth of the chorion. A hysterotomy and biopsy should be done if curettage is negative and the presence of a chorioma is suspected or recurrent bleeding is present.
2. The prognosis and indications of treatment can be made with relative safety from the histologic examination. Absence of the connective tissue core means malignant chorioma.
3. The treatment of choice of typical malignant chorionepithelioma is hysterectomy, even if metastases are present, as the latter have been known to regress following removal of the primary growth.
4. It appears that radiation therapy in combination with surgery may improve the prognosis of surgical treatment. However, the number of cases reported in the literature as successfully treated with irradiation is too small to warrant any positive conclusions.
5. Careful examinations and early diagnoses are the only criterions for a successful therapy of the highly malignant tumors of the chorion.

REPORT OF CASES

Case 1.—Mrs. McK., aged 32, sextigravida and quintipara, admitted to St. Mary's Hospital, Sept. 21, 1918, had had hemorrhages from the right kidney three months previously. A diagnosis of malignant tumor of the right kidney was made from the pyelogram. Because of the pregnancy it was treated with high voltage roentgen therapy, which arrested the bleeding.

September 23, a fetus with membranes intact was expelled spontaneously. Microscopic examination revealed a typical malignant chorionepithelioma. The kidney tumor was then considered a metastasis. Radiation therapy was advised and 2,040 mg. element hours of radium filtered with 2 mm. of brass was given within the uterus and a 150 per cent erythema dose of x-rays was applied to the center of the pelvis through suprapubic and sacral fields.

The patient has remained well.

Case 2.—Mrs. E. S., aged 32, primigravida, primipara, seen in consultation, April 28, 1926, had an amenorrhea from November, 1925, until Feb. 14, 1926, when uterine hemorrhages occurred. These stopped while the patient was kept in bed at absolute rest but immediately reappeared on her arising. April 7 a mole was expelled. A microscopic examination was not made.

The hemorrhages continued and within two weeks bimanual examination revealed large masses of unknown nature in both parametria. April 28 a panhysterectomy was done. The ovaries were the size of large oranges. Microscopic examination revealed a typical chorionepithelioma. The patient died from sepsis and peritonitis, May 16.

Case 3.—Mrs. B. O., aged 20, primigravida, nullipara, was referred from the Cook County Hospital to Mercy Hospital for radiation therapy of a typical chorionepithelioma malignum with extensive metastases in the vagina. She gave a history of amenorrhea of two months' duration since Aug. 6, 1927, followed by severe metrorrhagia, which was still existent on admission. She had marked vomiting of pregnancy. A mole was expelled, Jan. 15, 1928, which was followed by pyrexia. January 22, extensive invasive and ulcerative growths were found in the left vaginal wall and parametrium. Microscopic examination of tissues revealed a typical malignant chorionepithelioma.

The treatment consisted in the intra-uterine insertion of 2,400 mg. element hours of radium filtered with 2 mm. of brass and the application of 800 r units of x-rays each to a suprapubic and a sacral field from January 31 to February 14.

The patient recovered anatomically and has remained well to the present time.

Case 4.—Mrs. S. M., aged 22, secundigravida, secundipara, admitted from the Cook County Hospital for radiation treatment of brain metastases due to a recurrent chorionepithelioma, Feb. 10, 1928, had had uterine hemorrhages for six months prior to a panhysterectomy performed for the hemorrhages in September, 1927. Seven weeks later intense headaches developed accompanied by a left-sided paralysis, and in December, 1927, a tumor was discovered in the pelvis. A biopsy was then performed which revealed a typical malignant chorionepithelioma. X-ray doses of 800 r units each were applied to the brain and to the pelvic tumor. However, the patient succumbed within three months.

Case 5.—Mrs. A. C., aged 39, was admitted to the service of Dr. O'Donohue, Sept. 9, 1928, stating that she had had an abortion in March, 1926, which was followed by a continuous bleeding from the uterus. A curettage followed by the intra-uterine insertion of radium was made in September, 1927. A microscopic examination was not made. In May, 1928, persistent uterine hemorrhages, malodorous discharge and pelvic pain appeared. A panhysterectomy was performed, September 12. The histologic examination revealed a typical malignant chorionepithelioma. Short wave x-rays were applied to the pelvis from October 2 to 15, 800 r units being given to the midpelvic region. The patient has remained well.

Case 6.—Mrs. F. G., aged 18, primigravida, nullipara, admitted, May 13, 1929, had had an amenorrhea for three months and uterine bleeding for the last four days. Examination revealed an open cervix, an enlarged uterus, the size of an eight weeks' pregnancy, and a protrusion from the cervix of dark bluish grapelike masses. Biopsy revealed a malignant chorionepithelioma. A panhysterectomy was done, May 14, and a dose of 800 r units of short wave x-rays was applied to the midpelvis from June 1 to June 29. The patient has remained well.

Case 7.—Mrs. C. A., aged 21, primigravida, nullipara, admitted to the service of Dr. Vaughn, Sept. 6, 1929, had had an amenorrhea for five months and on September 12 a mass was expelled spontaneously from the uterus, which was followed by a continuous bleeding. A curettage was done, September 16, but the bleeding continued.

The patient reentered the hospital, October 7. A biopsy revealed a typical chorionepithelioma, and a panhysterectomy was immediately performed. The patient is well at the present time.

Case 8.—Mrs. M. L., aged 33, primigravida, nullipara, admitted, Nov. 7, 1929, had had hypermenorrhea for four months, followed by profuse and continuous metrorrhagia for the past two months. A roentgenogram revealed a fetus in transverse position in the lower uterine segment and an unusually large area of the supposedly amniotic sac (fig. 1). A spontaneous abortion occurred within twelve hours, a fetus of apparently three months size and a normal placenta being expelled. The uterus did not undergo involution. An examination, November 18, elicited an open cervical canal and a soft mass in the right posterior uterine wall. An immediate diagnostic curettage was made. Examination of the frozen section revealed a typical *chorionepithelioma malignum* (figs. 2 and 3). A panhysterectomy was immediately performed. Short wave x-rays were applied to the pelvis, the dose being 800 r units in the midpelvis. The patient has remained well so far.

ABSTRACT OF DISCUSSION

Dr. Bernhard Friedlander, Detroit: This paper shows the difficulties that exist in making a clinical and pathologic diagnosis of tumors of the chorion. Of 35,000 surgical specimens examined at Bellevue Hospital, only one chorionepithelioma was found. The severity of this growth depends on whether the Langhans cells or the syncytial element predominates. The Langhans type is slow growing, while the syncytial type is rapidly growing with an early tendency to metastasize. The histology of chorionepithelioma is well established by the work of Marchand, L. Fraenkel and others; nothing of importance has been added. There still exists a great deal of confusion in the biologic problem of this malignant growth and of hydatidiform mole. For a long time it was known that in hydatidiform mole and chorionepithelioma there is a formation of lutein cysts (pseudocorpora lutea or corpora lutea atretica) which must be due to some substance that has an action on the ovaries. Zondek and Aschheim, Evans and Smith have shown this formation of lutein material to take place after the implantation of the anterior pituitary and ovarian substance in animals. Murati and Adachi could produce the same results with placenta. Karl Ehrhardt found in one case of chorionepithelioma 260,000 mice units and in another as high as 520,000 mice units in 1 liter of urine. In a normal pregnancy there are no more than 8,000 to 10,000 mice units to the liter of urine. So it was evident that the formation of lutein cysts in hydatidiform mole and chorionepithelioma was due to the action of the hormone of the anterior pituitary body. Oscar Frankl demonstrated that the resistance of the mother's organism plays a great part in the formation of chorionepithelioma. He has shown that the serum of a normal pregnant woman is able to destroy fetal tissue from placenta, liver or kidney, while the serum of a woman who suffers from chorionepithelioma does not possess this lytic action. He concluded from this that the reason for the formation of chorionepithelioma must be found in the blood of the pregnant woman who shows an absence of syncytiolytic properties of the serum. He also believes that the spontaneous cures are due to a recovery of the syncytiolytic properties of the woman's serum.

Dr. Emil Novak, Baltimore: There is no field in gynecologic pathology in which mistakes are more readily made than in this one. There are several reasons for this. The tissue that makes up a chorionepithelioma differs little in its microscopic appearance from the tissue found in normal pregnancy and in the benign hydatidiform mole. The characteristic tissue, of course, consists chiefly of Langhans' cells and syncytial cells. It is true that in some cases of chorionepithelioma one finds definite evidence of anaplasia, such as mitoses, but, in the main, the value of this criterion is much less in this group of tumor than almost any other group. The normal pregnancy picture, that seen with the benign hydatidiform mole, and the malignant picture of chorionepithelioma, represent a gradation analogous to that seen between normal skin, benign skin papilloma and malignant epithelioma. Difficulty in diagnosis occurs from the fact that the trophoblast is an invasive tissue even in normal pregnancy, its cells often pushing into the musculature and into the veins. Moreover, there is a sort of physiologic metastasis, so that particles of trophoblast are transported to distant organs, especially the lungs. For this reason, one must in some cases be influenced largely by the degree of invasiveness and the presence of evidences of destruction of the normal musculature of the uterus. In most cases of chorionepithelioma the normal villous pattern is lost, although this is not an infallible criterion. There have been many efforts made at classifying these trophoblastic lesions, the best one probably being that of Ewing, who distinguishes a sort of intermediate group between the benign hydatidiform mole and the chorionepithelioma. This intermediate type he designates as chorio-adenoma destruens. The logic of this has never appealed to me because this type of growth is really malignant. It recurs after removal, it invades adjoining tissue, it metastasizes, it does everything that a malignant tumor does, though to a somewhat lesser extent than the chorionepithelioma. Whether it can be recognized in the individual section or not, every tumor is benign or malignant, and one ought to be content to recognize only two chief forms of choriomatous tumor, the chorioma malignum and the chorioma benignum. The first of these is what is commonly called a chorionepithelioma and the second the benign hydatidiform mole.

Dr. H. C. Mack, Detroit: Dr. Schmitz has referred to the Aschheim-Zondek reaction in chorionepithelioma and hydatidiform mole. Two cases of chorionepithelioma which we followed by means of this reaction gave us some valuable information regarding diagnosis and prognosis. One case developed following hydatidiform mole at four months. Panhysterectomy was performed. A small nodule infiltrated the myometrium. The Aschheim-Zondek reaction was positive before operation, remained positive three weeks after operation, and became negative after the patient had had several courses of roentgen and radium therapy. The second case was one of chorionepithelioma developing in a patient who had had nine successive hydatidiform moles; in this, her tenth pregnancy, she developed chorionepithelioma. The Aschheim-Zondek reaction was positive one month before the primary operation and remained positive after operation for four months, in spite of roentgen and radium therapy following panhysterectomy. Two months later the patient developed metastases in the vagina. These metastases were removed but the Aschheim-Zondek reaction remained positive. The patient left the city and we do not know what has happened. We have made studies of the urine of patients with hydatidiform mole and chorionepithelioma. We found that there was a high potency of anterior pituitary hormone. In hydatidiform mole a dilution of 1 : 5 gave a very strong positive reaction; in chorionepithelioma a dilution of 1 : 11. We made extracts from the tumor tissue of chorionepithelioma and obtained positive reactions, in a dilution of 1 : 14. Tumor implants also gave positive reactions. We have under observation a patient with a hydatidiform mole who was curetted after expulsion of the mole four months ago. The urine of this patient is still giving strong positive reactions in spite of a subsequent curettage. The uterus is still enlarged and soft; the menses are regular but somewhat abnormal; there is slight spotting. We are somewhat hesitant about saying that this patient has chorionepithelioma, but we believe there is some evidence that there is still proliferating chorionic tissue in utero.

Dr. Henry Schmitz, Chicago: The diagnosis should be based on the pathologic and clinical observations, especially recurrent severe hemorrhage following a supposed abortion or full term labor. The Aschheim-Zondek reaction will be of great assistance. Persistence of reaction may mean mole or chorionepithelioma. The reason I found so many patients with malignant chorionepithelioma was that these patients were referred for uterine hemorrhages possibly of malignant origin. There were only three patients who first sought help for bleeding of abnormal character. The others had been treated somewhere else, sometimes months before, and no diagnosis was made until they were sent to me on account of a suspected malignant condition. Otherwise, I am certain, I would not have seen so many cases. Hydatidiform mole, placental polyps and other conditions simulating malignant chorionepithelioma were not considered as it was my desire to discuss the malignant tumors of the chorion and the possibility of obtaining gratifying results of treatment especially with a combination of surgery and radiation therapy.

HYPERPLASTIC TUBERCULOSIS OF THE DUODENUM AND TERMINAL ILEUM

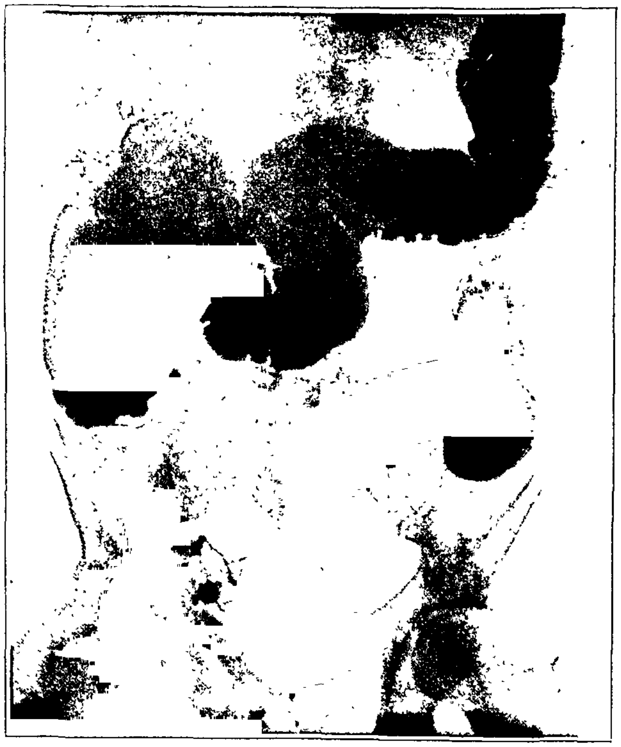
REPORT OF A CASE *

JOHN DAY GARVIN, M.D.
PITTSBURGH

Hyperplastic tuberculosis of the terminal ileum alone, without coexistent involvement of the cecum, is extremely rare. Involvement of the duodenum in the same process has never hitherto been reported.

REPORT OF CASE

A man, aged 24, seen for the first time through the courtesy of Dr. R. R. Snowden, Oct. 19, 1927, complained of diarrhea which had had its onset in February, 1925, there being at that time from six to ten bowel movements a day with no blood and no griping. After a few weeks this subsided; following dietary changes, he felt better, the stools became formed, and the number of movements was reduced to one a day. His weight then reached 154 pounds (70 Kg.). A year later (1926) he had, once a month, a recurrence of his diarrhea, lasting from two to three days, most of them abating spontaneously. At times he would have a temperature of 102 F. and a leukocytosis of as high as 14,000. Three weeks prior to the time I first saw him, he had had such an attack; the bowel movements were quite frequent and of a bad odor, but there was no blood or griping.



Hypertrophic tuberculosis of terminal ileum.

The physical examination was essentially negative when done by me (and had been persistently so for the two years previous when under Dr. Snowden's care, with the exceptions just noted) save for a complete indirect inguinal hernia on the right and a generalized abdominal tenderness of mild degree. He weighed then 127 pounds (57.7 Kg.).

Dr. George W. Grier had roentgenographed his stomach previously and had noted persistent duodenal deformity, which he attributed to a probable ulcer. In the light of subsequent events, this observation was quite significant. Stereoroentgenograms and repeated physical examinations of the chest were all negative. Fluoroscopic and roentgenographic examinations of the colon were done by me four times over a period of two years and each had been quite normal. At one time a careful stool examination showed the presence of many *Endameba nana* organisms, usually nonpathogenic. Nevertheless, acetarsone and chiniofon were given, at various times, without any appreciable improvement.

Repeated proctoscopic examinations were negative. Throughout all this time, dyspeptic symptoms, described by the patient as sour gas, belching, soreness in the pit of the stomach and gas pains in the pit of the stomach when he had diarrhea, were prominent. The blood Wassermann reaction was negative, many sputum tests were negative and the gastric test meal showed a total acidity of 20 and a free hydrochloric acid value of 10. Urinalysis was negative.

Aug. 16, 1929, he appeared, definitely emaciated, and complained of being "bloated." His weight was 123 pounds (56 Kg.). At this time another roentgen examination of the colon was done. The colon itself appeared quite normal, as it had before. However, when the barium had flowed into the terminal ileum, that part did not exhibit any spasticity or filling and emptying phenomena but held the medium evenly and to the palpating hand presented a definite, infiltrated, thickened wall. The remark of an assisting nurse, "It feels just like a rope," was most descriptive, as shown in the illustration. The diagnosis of hyperplastic tuberculosis of the terminal ileum was made and operation advised. The patient refused.

When seen again, September 30, he was definitely worse and complained bitterly of heartburn, nausea and vomiting. Roentgen examination of the stomach at this time showed a large, obstructed organ, with retention 3, after six hours. Operation was urged in order to relieve the retention, no diagnosis other than "lesion at the outlet" being made.

October 7, he was operated on by Drs. W. A. Dearth and H. E. DeWalt, who explored the right lower quadrant before directing attention to the stomach. The terminal ileum was markedly thickened for a distance of about 15 cm. from the cecum and the serosa was studded with tubercles, giving it the "sandpaper appearance suggestive of tuberculosis" noted by Erdman.[1] The cecum was uninvolved. The stomach was normal aside from some hypertrophy but the duodenum was markedly thickened and studded with tubercles much the same as was the ileum. Practically complete obstruction of the pylorus had resulted. There was no other evidence of involvement throughout the abdomen. There were no enlarged glands and the terminal ileum was freely movable. Because of the very poor condition of the patient, surgery other than gastro-enterostomy to relieve the obstruction was not attempted. The patient's family was informed of the conditions found and told that resection of the affected bowel would ultimately be necessary.

His convalescence was uneventful and on Jan. 3, 1930, his weight was 147 pounds (67 Kg.) and he was feeling very well. He was having but little diarrhea and no dyspepsia of any kind. February 11, he felt "dull and heavy in the stomach," was having some diarrhea, and his weight had dropped to 144¾ pounds (65.8 Kg.). Since that time there has been no improvement in his condition, the diarrhea and bloating have become a bit more noticeable, and his weight, May 9, was 134½ pounds (60.7 Kg.). Physical examination on this last date revealed a readily palpable, elongated tumor in the right lower quadrant. This could not be palpated at any time before the operation.

COMMENT

Tuberculosis of the intestine exists in four forms, according to the French classification:[1] 1. The common ulcerating type. 2. The stenosing or cicatricial type, resulting from contraction of the healed ulcer. 3. The enteroperitoneal type, combining ulceration, hyperplasia and involvement of the adjacent peritoneum, mesentery and lymph nodes. 4. Chronic hyperplastic tuberculosis. According to Lemon,[2] but two types are usually distinguished: 1. The ulcerating type, practically always secondary to pulmonary tuberculosis and a not uncommon complication in tuberculous patients. 2. The hypertrophic type, which was first described by Hartmann and Pilliet[3] in 1891 and is evidence of the successful reaction of the body against organisms that are either few in number or attenuated in virulence. It is a manifestation of the natural ability of the body to care for infection and has been described as the real surgical tuberculosis.[2] Infection probably occurs through the blood or lymph stream and the lesion takes the form of a localized hyperplastic structure, formative rather than destructive.

* Read before the Section on Radiology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 27, 1930.

[1] Erdman, Seward: Hyperplastic Tuberculosis of the Intestines, Ann. Surg. 71: 637-647 (May) 1920.

The most frequent seat of the disease is the ileocecal region, the tumor mass often attaining great proportions and resembling, macroscopically, carcinoma. Occasionally the rectum is involved. Involvement of the small intestine alone is rare, Lartigau[4] reporting but two cases. Masson and McIndoe[5] reported four others from the literature, their case being the seventh on record in which the process was confined to the ileum. This case is, therefore, the eighth in which the ileum is involved to the exclusion of the cecum and the first in which involvement of the duodenum is also present.

The most striking feature of the disease is the extremely thickened intestinal wall. Lartigau in describing it says "The wall of the intestine feels firm and is of a whitish or grayish color, occasionally studded with yellow points owing to the presence of caseous tubercles." He also speaks of narrowing of the lumen as being almost constant, the stenosis being produced, in such a case, by hyperplasia of the tissues of the wall. In this case the effect of the stenosis was noted more in the duodenum than in the ileum at the time of exploration. Ulcers are rarely absent in all portions of the mucosa, even though they are not at first apparent. The furred edge of the bowel, as noted in the roentgenogram, is probably caused by ulceration. The rises in temperature and the occasional leukocytosis as noted in the patient's history probably resulted from this factor also. Polypoid and papillomatous formations are often seen.

It is a disease of long duration. The chronicity and the low grade of inflammation are believed by Masson and McIndoe to be due "either to an attenuated bacillus" (as noted by Lemon) "or to one of low virulence elaborating small quantities of exotoxin sufficient only to produce proliferation and not necrosis."

Regarding the etiologic factors, Lartigau says that "the whole subject seems to be wrapped in a certain amount of obscurity." The fact that pulmonary tuberculosis is usually absent or that when it is present it is as a secondary affair was noted by the earliest commentators on the subject. Lartigau believes it to be primarily intestinal in origin. This recalls the statement of von Bering that the tubercle bacillus may be ingested as well as inspired.

SYMPTOMATOLOGY

Symptoms are somewhat indefinite. The earliest are usually dyspepsia, nausea and occasionally vomiting. Abdominal pain is often present. Diarrhea and constipation often alternate. In one of Pilliet's cases, diarrhea was persistent. The abdomen is often tympanitic and there is usually definite tenderness in the right lower quadrant. Koenig[6] summarizes the symptoms as "ballooning of the intestine, visible peristalsis, clapotage, borborygmi accompanying the colic and the appearance of an elongated tumefaction." This case has not progressed to the point at which such obstructive phenomena appear.

TREATMENT

Radical resection of the affected segment and intestinal anastomosis afford the only recourse. W. J. Mayo[7] reports several cases of ileocecal tuberculosis in which, anastomosis having been done preliminary to bowel resection, the patients apparently obtained complete relief, obviating the necessity of later resecting the affected segment of bowel.

That resection could not be done and subsequent microscopic evidence obtained in this case is unfortunate and renders my diagnosis vulnerable. However, I shall hope to present this later when and if the patient consents to the bowel resection.

5004 Jenkins Arcade.

ABSTRACT OF DISCUSSION

Dr. Lawrence Reynolds, Detroit: Dr. Garvin has given an interesting discussion of a rather unusual type of tuberculosis. Tuberculosis in the cecum and ascending colon and other parts of the large bowel is not infrequent in tuberculosis sanatoriums or even in office practice. Tuberculosis of the duodenum, on the other hand, is an extremely rare condition apparently and, if I judge correctly, Dr. Garvin believes this to be the first reported case. There have been a few other cases reported. Cohen reported a case in the *Medical Journal and Record* in 1928 in a boy, aged 15 years, who had symptoms for a long time simulating appendicitis. Operation was refused. The patient was seen again after nearly a year and a roentgen examination was made. In addition to the clinical signs in the right lower quadrant, the boy showed definite evidence of gastric pyloric obstruction, but the type could not be determined from the roentgen examination. When exploratory operation was made, a chronically inflamed appendix was found which was then interpreted as being tuberculous, as was also the obstructive lesion at the pylorus. It was impossible to resect the duodenum, but the glands about the duodenum and some of the tissue removed showed definite evidence of caseous tubercles, so that the diagnosis was determined entirely from glands taken in the proximity of the lesions, which parallels more or less the condition exhibited in Dr. Garvin's case. This patient a year afterward was well and without evidence of pulmonary tuberculosis. One other case that I found in the literature was reported by Buckley in the *U. S. Veterans' Bureau Medical Bulletin* in 1928. This patient was a Negro, aged 26, who had an extensive bilateral pulmonary tuberculosis, with evidence of intestinal tuberculosis. At autopsy a definite tuberculosis of the duodenum was found. The cases, however, are extremely rare. I believe that Howell, in making an analysis of 116 or 119 autopsies, found only 5 to present tuberculosis of the duodenum. The diagnosis of intestinal tuberculosis from a roentgenologic standpoint is of extreme interest. Dr. Garvin's case of tuberculosis of the duodenum will undoubtedly stimulate others to search for it, because, while it is infrequent, it must be a little more common than one is apt to think.

Dr. L. T. Le Wald, New York: I have had one case of primary tuberculosis of the cecum. That is a point that ought to be emphasized. As I understand it, in Dr. Garvin's case there was no pulmonary lesion. My patient was a man who had had his appendix removed, and it shows the value of routine examination of every removed appendix because the pathologist immediately returned a diagnosis of tuberculosis of the appendix.

[7] Mayo, W. J.: Personal communication to the author.

Lawrason Brown's work had just come out and I thought I would see if I could demonstrate whether the patient had tuberculosis of the cecum or not. He responded to the criteria that Brown and Sampson have given and Dr. Reynolds has just mentioned and as Pirie first observed: namely, the lack of filling of the cecum. The diagnosis was confirmed also by a barium enema, which showed rapid emptying of the cecum, so that I was able then to say that there was an area involving the cecum and extending up the ascending colon for a distance of perhaps 2 inches. With that definite knowledge, the surgeon, Dr. Downes, who had taken out the appendix, operated again and did a resection, putting the ileum into the transverse colon. The man made a perfect recovery and I watched him and roentgenographed him again for a period of about four years. He remained absolutely cured. It is now probably eight years and, as far as I know, he has had no further evidence of tuberculosis either in his digestive tract or in his lungs. I feel that this point of primary tuberculosis in the digestive tract should be stressed.

Dr. John Day Garvin, Pittsburgh: I forgot to say that Dr. Grier roentgenographed this young man about two years before I got him and noted a deformed duodenum and made a diagnosis of probable ulcer. There was nothing clinically to go with it and I didn't bear down very heavily. In the light of subsequent events, Dr. Grier's diagnosis was significant. I do not have the films to show because in the meantime Dr. Grier cleaned out his back films. I would like to emphasize and reemphasize, if I might, the fact that we are not talking about the ulcerative types of tuberculosis. This is a chronic hyperplastic type of tuberculosis of which, as I say, there are but eight cases reported. There may be some ulceration. Hardinghouse says there is only it isn't apparent. The big fact is hyperplasia, thickening of the wall and stenosis of the lumen.

TRICHINOSIS AND ITS OCULAR MANIFESTATIONS *

LELAND F. CARTER, M.D.

DETROIT

The observations of the ophthalmologist are of invaluable aid in the diagnosis, treatment and prognosis of many systemic and neurologic diseases. This is particularly true in regard to examination of the eyegrounds and the perimetric fields. Although he could never hope to attain this enviable degree of diagnostic precision by external examination of the eye, certainly there are times when the external appearance of the eye and its adnexa will present some of the first evidences of a grave disorder.

In this category falls trichinosis, a most interesting parasitic disease which probably presents itself for diagnosis not infrequently. Because of its varied symptomatology trichinosis is, unless by chance, almost as frequently undiagnosed. This is evidenced by the comparatively few cases reported in the literature as against the observations of H. U. Williams,[1] who in 505 autopsies in which the disease had not previously been suspected found 5.34 per cent of trichinosis. That the ophthalmologist may in a measure alter these statistics it is hoped will be brought out in this paper.

Of the ocular signs and symptoms of trichinosis, by far the most spectacular and characteristic is that of chemosis of the bulbar conjunctiva. It is most singular that this striking ocular sign has heretofore been so inadequately emphasized. It presents a picture not likely to be confused with any other. Occurring bilaterally as a rule, in the first few days of the disease there is a chemosis of the bulbar conjunctiva of a pale lemon jelly appearance with only slight inflammatory reaction. The chemosis is limited to the conjunctiva overlying the external and internal rectus muscles, gradually fading out to the limbus. This pathologic picture is undoubtedly brought about by the early invasion of the rectus muscles by the trichinella parasite. In ten or more cases that I have seen, this sign was prominent in all but one case. Generally speaking, this incidence of occurrence is much too high since most of the cases were seen in an eye infirmary. It may, however, be conservatively conjectured that this characteristic conjunctival reaction can be seen in 50 per cent of the cases. Late in the course of the disease the percentage will be much less, since the chemosis often lasts but a week and has become absorbed at the stage of maximal involvement of the skeletal musculature. The mere presence of chemosis of the conjunctiva does not alone justify the diagnosis of trichinosis but should suggest to the observer other channels of investigation. Occurring concurrently with the conjunctival chemosis will generally be seen an edema of the lids which later extends over the temporal and frontal regions and may finally involve the entire face. Painful movement of the eyes is frequently an associated and significant symptom. Exophthalmos, conjunctival ecchymosis, midriasis and retinal hemorrhages both superficial and deep are other ocular manifestations of the disease which occur with varying degrees of frequency.

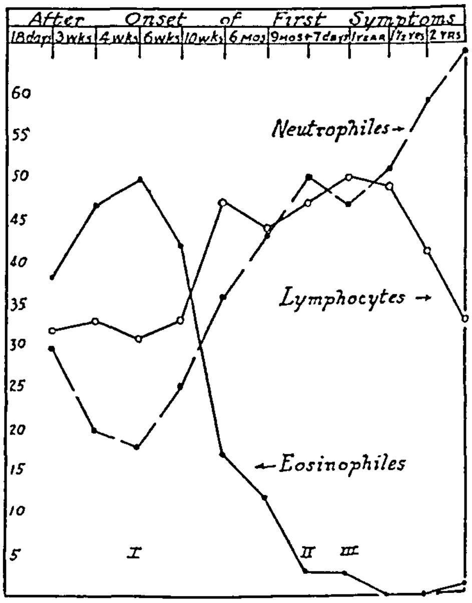

Fig. 1 (case 1).—At I, only minor symptoms of the disease had been present for the past two weeks; still, the eosinophil count continued to climb and the neutrophil count to fall; III is a confirmatory test of II taken seven days later.

Herrenschwand[2] has had the rare good fortune of examining the trichinella-infested eye microscopically at autopsy. In his observations the conjunctiva of the bulb and retrotarsal folds showed a marked round cell infiltration. There was a predominantly loosened structure of the epithelial cells of the conjunctiva which in many instances showed evidence of necrosis. Goblet cells were also seen to be in superabundance. The eye muscles were examined in section from the attachment of the ligament far into the belly of the muscle. In

[2] Von Herrenschwand, F.: Arch. f. Ophth. **119**: 374, 1927.

all, a large number of fully developed and encapsulated trichinae were present. In contradistinction to their abode of predilection in the rest of the skeletal musculature, where they were found at the ligamentous attachment, here they were found mainly in the belly of the muscle and as far back as 11 mm. Otherwise the pathologic conditions were identical. The number of trichinae found in the eye muscles was impressively large and exceeded that found in the muscles elsewhere. The cornea and sclera were spared. The uvea presented no pathologic change except in the choroid. The vessels here contained an increased number of eosinophils as would naturally be expected from the general blood picture. The retrobulbar portion of the optic nerve showed a marked increase of the cells in the interstitial neuroglia tissue, and also an inflammatory infiltrative area in the adventitia of the central artery of the retina. The latter was well preserved and presented a few small hemorrhages, some of which were in the nerve fiber layer and others in the nuclear layer. Further there was found a row of characteristic round accumulations of cells particularly in the peripheral portions of the retina, several being found in the region of the ora serrata. These sharply circumscribed accumulations of cells lay for the most part in the two nuclear and outer plexiform layers, causing them to be displaced and bellied out from their normal positions. Several lay directly on the pigment epithelium of the retina in the layer of the rods and cones, projecting the external nuclear layer inwardly. The location of the accumulations of cells was determined by the position of the retinal capillaries; the character of the pathologic process was indicated by a proliferation of the cells of the capillary walls. The walls of the capillaries were at times thickened, hyalinized and dilated. In many of the accumulations an edema of the tissues was noted as well as a marked inflammatory infiltration with noneosinophilic leukocytes and lymphocytes. In part this made up the entire picture. In all, ten such accumulations were found, but this does not indicate their actual count since the sections were not all examined. In six, young trichinae were found.

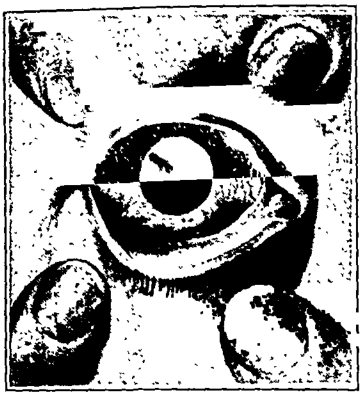

Fig. 2 (case 2).—Chemosis of bulbar conjunctiva overlying both the internal and the external rectus muscle in each eye.

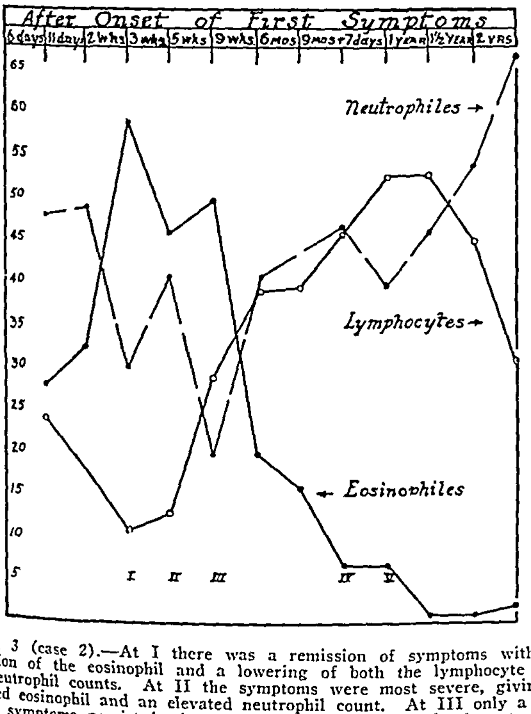

Fig. 3 (case 2).—At I there was a remission of symptoms with an elevation of the eosinophil and a lowering of both the lymphocyte and the neutrophil counts. At II the symptoms were most severe, giving a lowered eosinophil and an elevated neutrophil count. At III only a few minor symptoms persisted, the neutrophil count was at its lowest point and the lymphocyte count had returned to normal. V was a confirmatory test of IV taken seven days later.

The ocular signs and edema of the face gradually subside, usually after the first week following their appearance. On the other hand the early general symptoms—malaise, constipation or diarrhea, gastritis, hyperpyrexia ranging from 100 to 105 F., and chills with profuse sweating—persist with a tendency to remissions. The migratory stage of the trichinella being now well established, generalized involvement of the skeletal musculature assumes a prominent rôle in the symptomatology. The more active muscles—tongue, extra-ocular, facial, diaphragmatic, intercostal and those of the extremities—are the earliest and most acutely involved.

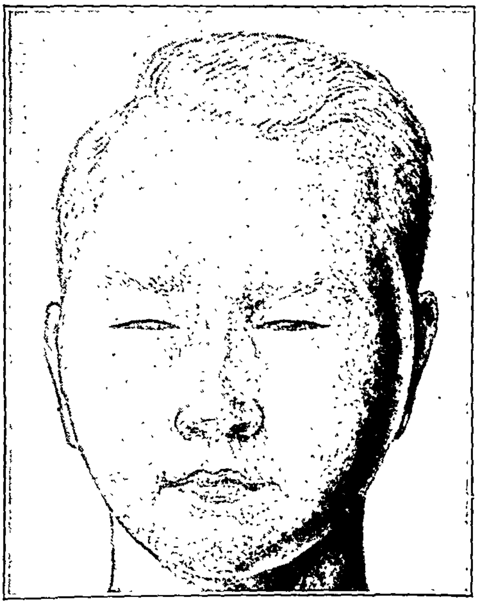

Fig. 4 (case 2).—Edema over maxillary, frontal and temporal regions; proptosis of each eye, with extra-ocular movements limited and painful.

Occurring early in the disease there is invariably an eosinophilia ranging from 10 to 80 per cent. In no other disease is this finding so constant or of such a high percentage. It is present almost at the onset of the first symptoms or even in the absence of any other sign or symptom indicative of trichinella infestation. Nor does the percentage or the length of time of the persistence of the eosinophilia give any indication as to the severity of the infestation. Thompson[3] reported a case in which the temperature was 105 F. and the white blood count 10,000, with 70 per cent polymorphonuclears, 20 per cent lymphocytes and 12 per cent eosinophils. During convalescence with a normal temperature the eosinophilia rose to 62 per cent.

---

[3] Thompson, W. G.: Am. J. M. Sc., August, 1910.

As in the differential blood count, further burden of proof or confirmation of diagnosis falls on the laboratory in the demonstration of the trichinella larvae. This is most readily done by examination of a section of the affected muscle under the microscope. Since it will not always be found easy to obtain the patient's permission for such a procedure, the importance of examination of the blood for the offending parasite should be emphasized. Trichinella larvae are found in the blood stream during the period of migration from the intestinal tract to the affected muscles, which in one of the cases here reported extended into the fourth week from the onset of symptoms. They were first demonstrated in the blood stream by Herrick and Janeway in 1909 and were found to occur in 33⅓ per cent of the cases. At autopsy the larvae have been found in the pericardial fluid, in pleural exudates, and in the cerebrospinal fluid. The adult male trichinella has been reported to be found in the stools, but in only a small percentage of the cases.

That there may be a great variation in the time and character of the onset, duration and intensity of the symptoms, especially in a family outbreak, is well demonstrated by these cases in a father, son and wife who partook of broiled pork chops on the evening of Dec. 12, 1927:

REPORT OF CASES

Case 1.—Mrs. B., the fourth day following the eating of pork, awoke, December 16, with a slight swelling of the right eyelids and cheek, general malaise, aching of the entire body, and a feeling of feverishness.

December 17, the edema had extended into the left eyelids and cheek. The bowels became constipated and the patient had severe chills with profuse sweats. Lactation of the breasts ceased. A blood culture was taken.

December 20, the temperature was 102 F., the pulse 118, and respirations 24. The report on the blood culture was "no growth." The bowels were constipated and the patient appeared quite ill. The edema had now extended over the entire face, beneath the chin, and over each deltoid region. She had no desire for food and vomited twice. A quick laxative was effectual.

December 22, the temperature was 100 F., the pulse 90, and respirations 20. The patient was greatly improved and now was able to be up a short period during the day. The tendency to constipation persisted.

.December 23, one week after the onset of symptoms, the patient complained for the first time of pains in the muscles of the legs and arms, which were described as cramps brought on when she started to walk, or to extend the legs while in bed. There were also various areas of edema and firmness of the skin, which were then considered areas of urticaria.

For an additional week the patient had a slightly elevated temperature, gradually improving generally. However, during this time and for several weeks thereafter she experienced rheumatoid pains in the muscles of the extremities, especially when putting them to use after an interval of rest.

Jan. 3, 1928, the patient was first seen by me, at which time she was apparently well. She complained only of occasional muscular pains. Examination showed a decided firmness of the deltoid and gastrocnemius muscles. There was no tenderness, pitting or discoloration of the skin. A blood smear was taken for a differential count (fig. 1). Microscopic examination of a centrifugated specimen of blood was negative for the presence of trichinellae.

Case 2.—Dr. B., December 23, eleven days after eating the pork, first noticed the beginning of a diarrhea and slight abdominal discomfort. The patient had previously been in good health. During the following few days these symptoms increased in severity with an accompanying headache, anorexia and general malaise.

December 28, the patient awoke with an edema of the eyelids which disappeared in a few hours. Although there were no definite muscular pains, he noticed that he was more easily fatigued than usual. An intractable diarrhea persisted.

December 29, I was consulted by the patient in regard to his eye condition, which he thought had resulted from the giving of alpine light treatments. His only complaint was of edema of the lids and conjunctiva. There was no photophobia, lacrimation or discharge. Examination showed considerable edema of the lids, especially the lower, and a characteristic chemosis of the bulbar conjunctiva overlying both the internal and the external rectus muscles in each eye (fig. 2). The corneas were clear; the pupils were equal and reacted well, and the fundi did not show any pathologic changes. The maxillary and frontal sinuses transilluminated clearly. The turbinates and mucous membrane of the nose were normal. No discharge was present. A tentative diagnosis of trichinosis was made. Mild mercurous chloride in divided doses followed by a saline cathartic the following morning was advised. A blood smear was taken for a differential count (fig. 3).

December 30, the patient awoke unable to open his eyes because of the increasing edema, which had now extended over the maxillary, frontal and temporal regions. There was quite evident proptosis of each eye, with extra-ocular movements limited and painful (fig. 4). Conjunctival chemosis had increased but no other ophthalmic signs were present. The temperature was 102 F.

Jan. 3, 1929, ten days following the onset of the symptoms, the patient's general condition was more serious; the ophthalmic signs remained the same. Blood was taken for a differential smear (chart 2). *Trichinella spiralis* was demonstrated in the centrifugated blood of the patient.

The patient's condition remained unchanged for several days with the temperature ranging from 100 to 104 F. in twenty-four hours. He had profuse night sweats, extreme diarrhea and prostration. Fluids sometimes to the extent of 2 gallons a day comprised the major part of his diet. A prescription of resorcinol, sodium bicarbonate, bismuth subcarbonate, heavy magnesium oxide and charcoal gave some relief of the gastro-intestinal symptoms.

January 8, eleven days after their first appearance, the edema of the lids and face together with the chemosis of the conjunctiva and proptosis were entirely gone. Extra-ocular movements were still painful, with some photophobia and severe frontal headache, especially after attempts at reading. Gastro-intestinal symptoms were lessened in severity but there still remained extreme general fatigue after the slightest exertion.

January 10 and 12 (the eighteenth and twentieth days of the disease), the patient experienced a most severe attack of painful respiration as a result of involvement of the intercostal and diaphragmatic muscles. One-fourth grain (16 mg.) of morphine sulphate was necessary for the relief of the pain and cyanosis. Ten cubic centimeters of blood was taken for examination. The laboratory report was positive for trichinellae.

Generalized weakness of practically all the voluntary muscles and pains in the lower extremity persisted for a further period of about three weeks, at the end of which time all signs and symptoms had gradually disappeared except for the abnormal blood picture (fig. 2).

Case 3.—Mr. B. did not note any untoward symptoms from eating the infested pork. This was explained at the time by the fact that the pork had been obtained from two different sources. However, a differential count of his blood several months later showed 4 per cent eosinophils, while on several occasions still later the count was normal or none at all were found.

COMMENT

A study of the blood in the first two cases was made at intervals over a period of two years, at the end of which time there was an entire absence of all the signs and symptoms of the disease. The eosinophil count was observed to be lowest during the acute stage of the disease, increasing with a remission of symptoms only to be reduced with each exacerbation. The neutrophil count was lowered in direct proportion to the increase in the eosinophils, and vice versa. With a gradual return of the eosinophil count to normal there was a corresponding increase in both the neutrophils and the lymphocytes. Behr[4] made somewhat similar observations except that he observed, in contrast to these conditions, that the lymphocytes followed closely the curve of the eosinophils in their return to normal. Here it is seen that, following a grave depletion of the neutrophils, the stimulus for regeneration affected both the lymphocytes and the neutrophils. The proportionate recovery of the lymphocytic count was much the greater, reaching a stage of mild lymphocytosis and then gradually receding to the normal.

The ease with which errors in diagnosis are made is well demonstrated in each of the cases that follow.

1. Mrs. B.'s condition was first diagnosed by her dentist as a "slight infection" of the maxilla and later by a consulting surgeon as septicemia following the extraction of a tooth.

2. Dr. B., after leaving my office, visited the office of another friend, who made the diagnosis of chronic nasal infection and acute conjunctivitis following alpine lamp treatments. He was seen the following day by an internist who was equally positive in the diagnosis of foreign protein sensitization.

3. Mr. B.'s case was undiagnosed, whereas had I made an early examination of the blood it would most probably have shown the eosinophilia of trichinosis.

Several methods of treatment have been suggested and tried with varying results. Algora y Nieto[5] reports prompt recovery in seven cases in which 0.45 Gm. of neoarsphenamine was injected intravenously two or three times. It is the opinion of most authors (Magath,[6] Schwartz, Alexander), however, that the treatment is as yet unsatisfactory. It seems quite logical that the administration of purgatives (mild mercurous chloride in divided doses and a saline cathartic the following morning) with the onset of the first symptoms will eliminate large numbers of the trichinae, with in turn thousands fewer of the larvae entering the blood stream. That it is impossible by this means to avert altogether the migratory period is well demonstrated in the second case reported, in which an intractable diarrhea was the first symptom.

SUMMARY

Two of the cases here reported demonstrated well the symptomatology of trichinosis. The one showed a conjunctival reaction characteristic of trichinosis which I believe is present in possibly 50 per cent of all cases. The other patient did not present this sign but might have had she been examined earlier in the course of the disease. The third case, if trichinosis, was asymptomatic.

Eosinophilia persisted for a period of from ten to twelve months with a subnormal neutrophil count extending over an even longer period of time. There was no apparent lowering of the patient's resistance to infections during this time.

Trichinella larvae were found in the blood stream. In one case they were found as late as the fourth week following the onset of symptoms.

The only dependable treatment of apparent value is early purgation.

78 Adams Avenue.

ABSTRACT OF DISCUSSION

Dr. E. V. L. Brown, Chicago: Dr. Carter has called attention to a thoroughly characteristic, diagnostic and heretofore unemphasized finding in trichinosis, namely, a lemon-yellow chemosis confined to the conjunctiva over the external and internal rectus muscles, found early in the disease and in something over half the cases, indeed, in all but one of the ten cases seen by him. The eosinophilia, invariably present and ranging from 10 to 80 per cent, should almost complete the diagnosis.

The ophthalmologist should therefore be a considerable factor in the early recognition of these cases, and if they occur in 5 per cent of people who come to postmortem, as reported by Mitchell, there must still be much trichinosis extant. To my knowledge I have never seen a case.

Dr. F. H. Verhoeff, Boston: My attention was first called to this condition of the bulbar conjunctiva by Dr. Parker of New York many years ago. It seems to me that both pathologists and the general profession have been slow to realize the importance of this symptom in trichinosis. We see a good many cases in the Massachusetts Eye and Ear Infirmary, and have learned to recognize it quickly. The condition is very characteristic. In the typical case there is congestion and a few little conjunctival hemorrhages over the rectus muscles, and in the marked cases there is more or less chemosis. I myself think that with this eye condition, elevation of temperature and eosinophilia one may be certain of the diagnosis and it is a waste of time to make any further examination, such as examination of an excised piece of muscle. While the organisms have been found in the muscles of the eye, I do not feel absolutely certain, as does the author, that their presence in the ocular muscles is the cause of the eye condition, for the reason that the latter occurs before there are any symptoms of involvement in the other muscles of the body. Many of these cases are very mild. I have no doubt that many pass unrecognized entirely, simply regarded as conjunctivitis, or edema of the conjunctiva, of unknown cause. I am sure that before Dr. Parker called my attention to them I had missed many of these cases, because I see so many now. Most of the patients do well. I do not think we have ever had a case in which death occurred. Some of them go through their courses without any especially alarming or unpleasant symptoms. In making the diagnosis one is helped if one gets a story of the patient having eaten pork and having had some gastro-intestinal disturbance previously; but even without this I think the condition of the eye and the eosinophilia justify one in making the diagnosis.

Dr. T. B. Holloway, Philadelphia: Within the past few months three suspected cases have been seen in my service. Should such a case be first seen at the office, I believe it would be quite easy to overlook the possibility of trichina in the early stage. In the cases I have seen the chemosis was not excessive, but there was some edema of the lids with moderate bulbar injection and in one instance tiny punctate hemorrhages. Ocular rotations were painful. In the most striking case there was some cough but no definite pulmonary signs. The temperature was about 103 F. There was a high eosinophilia. Up to the time I last saw them, the cases were not definitely proved by finding the trichina.

Clinical Notes, Suggestions and New Instruments

PERFORATION OF THE CECUM BY A TOOTHPICK, SIMULATING ACUTE APPENDICITIS

Samuel McLanahan, M.D., Baltimore

Intestinal perforation and resulting abscess formation due to an ingested foreign body have been mentioned recently in The Journal.[1] An article by Bearse[2] focused attention on the subject. The two outstanding characteristics of the abscesses have been their slow development with consequent large size, and their location in connection with the large intestine. An exception was the duodenal perforation reported by Douglas.[3] The rectum is said to be the most common site for perforation by foreign bodies. A recent case coming to my attention presented rather different characteristics and offers another problem in differential diagnosis.

REPORT OF CASE

B. F., *a man, aged 44, was admitted to the* Union Memorial Hospital, April 20, 1930, under the surgical care of Dr. William A. Fisher, having been referred by Dr. Joseph W. Ketzky. On the previous day the patient had first noticed a dull pain in the right side of the abdomen; at times the pain increased in intensity. It had persisted for more than twenty-four hours but was unaccompanied by any nausea or vomiting. There had been a tendency toward constipation. On examination the temperature was 99.8 F.; there was marked tenderness over the right lower quadrant, accompanied by a moderate degree of muscle spasm; there was no mass on abdominal or rectal palpation. The leukocytes were normal and the urine was normal. A tentative diagnosis of acute appendicitis was made and immediate operation advised. Through a McBurney incision, the contents of the right iliac fossa were examined. Palpation of the cecum at once revealed the presence of a foreign object within its lumen, possibly a piece of wire. Evidence of a small abscess was seen along the lateral wall of the cecum. The appendix appeared *normal and was removed in the routine* fashion, the stump being inverted through a purse-string suture of fine black silk. Better exposure was at once possible and a small perforation in the lateral wall of the cecum could readily be seen. This led into a small abscess containing only a few drops of pus; subsequent culture yielded *Bacillus coli.* Projecting through the hole in the cecum was a foreign object, which on removal proved to be an ordinary toothpick. Cigaret drains were placed down to the site of the abscess and the wound was closed in layers. Convalescence was uneventful except for a rather prolonged healing of the wound. At no time was there any evidence of a fecal fistula. The patient had no recollection of having ever swallowed the toothpick.

COMMENT

The acuteness of the onset, the small size of the abscess and the location of the lesion are the striking points of this case. Obviously, an intraperitoneal perforation would be more readily noticed and diagnosed than an extraperitoneal one. This would account for the early acute symptoms, which were noted before the formation of a large abscess was possible. Such has not been the case with the slow-growing, large abscesses of the sigmoid area. Cecal perforations, because of their proximity to the appendix, will necessarily receive more prompt surgical intervention. A differential diagnosis, however, from an inflamed or ruptured retrocecal appendix would be a long chance. An interesting observation, previously made, and supported by this case, is that these patients are rarely conscious of having swallowed a foreign body, be it toothpick or fishbone.

Union Memorial Hospital.

ORAL APPLIANCE FOR RADIUM TREATMENT *

J. B. Williams, D.D.S., and S. W. Budd, M.D., Richmond, Va.

An implantation of radon seeds into the bony structures of the oral cavity is not always desirable. The limited amount of soft tissue in the alveolar ridge and the hard palate makes the interstitial use of radium very difficult and at times impossible. In these locations a surface application of radium is indicated.

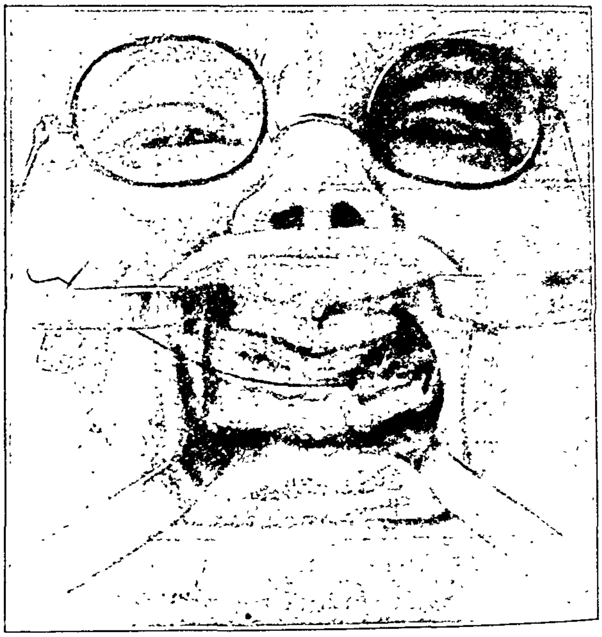

Fig. 1.—Appliance in position in mouth of edentulous patient.

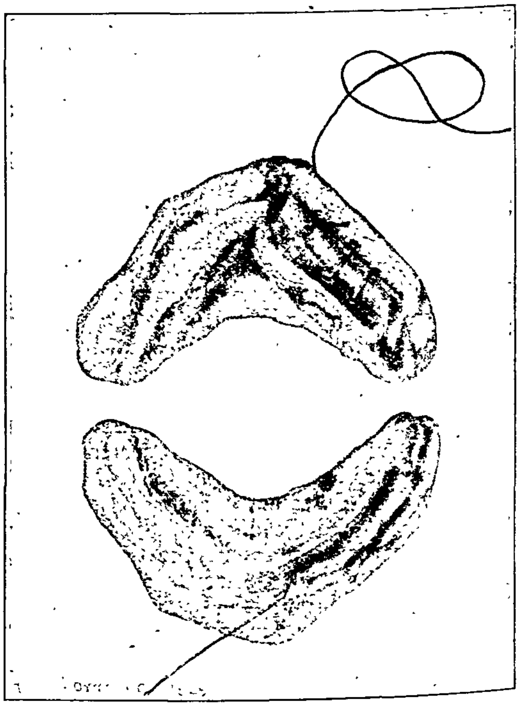

Fig. 2.—Upper and lower surfaces of appliance showing depressions to fit alveolar ridges and a deeper depression for retaining radium in a rubber container.

The great problem in oral applications is to get an applicator that will stay put. The movements of the tongue and muscles of deglutition will soon sweep ordinary applicators, such as forceps or pinch-cocks, from their anchorage. We experienced a great deal of difficulty in this regard until we commenced to use dental impressions made from a nonmetallic gum wax base. With them, we have been able to give treatments lasting over a period of hours without a great deal of discomfort to the patient.

GALLBLADDER VISUALIZATION IN JAUNDICED PATIENTS *

Hillyer Rudisill, Jr., M.D., Chicago

It is quite generally believed that it is not desirable to advise cholecystography in jaundiced patients; in the first place, because nonvisualization usually results, and, in the second place, because the reaction to the dye may be unduly severe.

In the course of the past eighteen months, ten jaundiced patients have been seen among a group of some hundreds coming in a routine manner for cholecystography. In all except one of these cases, the examination has yielded useful information without ill effects to the patients.

Tetraiodophenolphthalein sodium is excreted in the bile by the liver shortly after intravenous injection, and diverted into the gallbladder by the action of the sphincter of the common duct, if the subject is fasting. The filling of the gallbladder seems to depend almost entirely on the occlusion of the common duct. Once inside the gallbladder, the bile and dye become concentrated by the absorption of water until the material is dense enough for roentgen visualization.

There is no contraindication to attempted gallbladder visualization in obstructive or extrahepatic jaundice.

In the hemolytic group, tests for liver function usually do not reveal much impairment.

The mechanism of occurrence of toxic and infectious jaundice is uncertain. It is usually thought to be caused by a combination of liver cell damage and cholangeitis. This is the only group in which there could be any theoretical contraindication to cholecystography. The so-called catarrhal jaundice is a member of this group.

In eight of the ten jaundiced patients submitted to gallbladder dye injection, the clinical diagnosis was catarrhal jaundice. In seven of them there was normal visualization of the gallbladder without evidence of stone, and in the eighth the gallbladder was not visualized. The ninth case, deeply jaundiced, presented a well visualized gallbladder full of stones (confirmed at operation). In the tenth case the gallbladder was not seen and at operation a carcinoma of the common duct was found.

The dye used was tetiothalein sodium (N. N. R.), 3.5 Gm., dissolved in 30 cc. of triple distilled water, sterilized and filtered according to the instructions supplied by the manufacturer. It was injected intravenously at 4 o'clock on the afternoon preceding the filming. Films were made with the patient prone on the Potter grid (*a*) about sixteen hours after the injection of the dye and (*b*) about one hour later and perhaps forty-five minutes after the taking of a drink containing chocolate, fresh egg and malted milk.

SUMMARY

Ten jaundiced patients have been submitted to cholecystography. In eight the gallbladder was visualized, in two it failed to be visualized. None of the patients have suffered an unusual reaction to the dye.

CONCLUSIONS

1. Jaundice is not a contraindication to the intravenous administration of tetiothalein sodium.
2. It is advisable to give intravenous tetiothalein sodium solution to jaundiced patients as a possible means of helping to differentiate the causes of jaundice.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

SODIUM 2-OXO-5-IODO-PYRIDINE-N-ACETATE (INTRODUCED AS UROSELECTAN)

Sodium 2-oxo-5-iodo-pyridine-N-acetate (also designated as sodium-5-iodo-2-pyridon-N-acetate) has been introduced by Schering-Kahlbaum A. G. (Schering Corporation, distributor) for use in the radiographic visualization of the urinary tract under the proprietary name "Uroselectan." Since this name was tantamount to a therapeutic suggestion the Council recommended its replacement by an acceptable designation and accordingly the distributor is considering the adoption of the name Iopax, which the Council finds acceptable. The product is a definite chemical substance which promises to be an advance in the radiographic visualization of the urinary tract though its advantages, limitations and contraindications are at the present time not fully established. The product is suitable for experimental use by those who are versed in the technic of urologic examinations. In order to make available to physicians a concise and carefully considered statement of the introduction of the drug and the evidence for its use which is now available, the Council publishes the appended report prepared at its request by Drs. Bumpus and Braasch and extends at this time its appreciation to these investigators.

W. A. Puckner, Secretary.

REPORT ON SODIUM 2-OXO-5-IODO-PYRIDINE-N-ACETATE (INTRODUCED AS UROSELECTAN) TO THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION *

WILLIAM F. BRAASCH, M.D.
AND
HERMON C. BUMPUS, JR., M.D.
Rochester, Minn.

The idea of visualizing the urinary tract by intravenous injection of some chemical substance containing iodine was first brought forward by Rowntree, Osborne, Sutherland and Scholl in 1923, by means of a publication in The Journal of the American Medical Association. In their communication they demonstrated that the pelvis of the kidney, the ureter and the bladder could be rendered opaque to the roentgen ray by intravenous administration of solution of sodium iodide 10 per cent. Because of the toxicity of the drug in large doses and because of imperfect visualization of the renal pelvis in most cases, the method was not generally taken up by the profession.

In 1924, von Lichtenberg and Rosenstein repeated the work in conjunction with the perirenal pneumoradiographic method of Rosenstein. The same year Volkmann reported using the method, and in 1927 Lenardouzzi and Pecco published a report of their experience with it.

From 1921 to 1927, Binz and his assistant, Räth, synthesized seventy-three compounds of pyridine, with the idea of testing their germicidal properties in the urinary and biliary tracts when used intravenously. These they termed the "selectan" group of substances.

---

* From the Division of Roentgenology, University of Chicago Clinics.

* From the Section on Urology, the Mayo Clinic.

In 1928, Hryntschak, before a congress in Vienna, reported being able to visualize the urinary tract by intravenous injection of some substances the nature of which he kept secret. He published his work, with illustrations, in the *Zeitschrift für Urologie* in 1929 and demonstrated visualization of the urinary tracts of both animals and human beings. It has since been affirmed that these secret substances included sodium 2-oxo-5-iodo-pyridine-N-acetate but that he failed to obtain successful results in human subjects. The suppression of essential facts from Hryntschak's publication renders his work unsuitable for scientific evaluation.

Swick of New York, an American studying in Europe on a fellowship furnished by the Libman Foundation of New York, was asked by Lichtwitz, in the summer of 1928, to come to his clinic in Altona and study urologic cases. Binz had supplied Lichtwitz with some of the "selectan" group ("selectan neutral") of drugs to be tried in infections with cocci of the biliary and urinary tracts. Lichtwitz wrote (*Der Chirurgie* **2**: 357, 1930): "Auf Grund dieser Versuche und unserer ziemlich grossen Erfahrungen über die Unschädlichkeit der Präparate bei peroraler und intravenöser Darreichung schien die Anwendung der Selectane zur Kontrastdarstellung aussichtsreich. Herr Dr. M. Swick aus New York hat diese Prüfung durchgeführt. Ihm verdanken wir die Uroselectanmethode." (On the basis of these experiments and of our relatively extensive experience regarding the lack of untoward effects of the preparations by peroral and intravenous administration, the application of the Selectans as contrast mediums appeared promising. Dr. M. Swick of New York has carried out these trials. To him we owe the Uroselectan method.) The results on patients were promising, but the properties of the compound first used were not entirely satisfactory.

In the spring of 1929, after Swick had worked seven months at Lichtwitz's clinic, Lichtwitz advised Swick to continue his studies in Berlin. There he might have opportunity to take advantage of the extensive clinical material in the clinic of von Lichtenberg, and might be in a position to be in close relationship with Binz for the purpose of having the preparation perfected.

Von Lichtenberg expressed great interest in the results already obtained, encouraged Swick to proceed, and placed the necessary facilities at his disposal. Conferences with Binz and his associates led to the systematic trial of other substances of the "selectan" series, in the hope of avoiding the objectionable features of "selectan neutral." The compound which gave the best visualization and which had the least toxicity was found to be one of the "selectan" group of Binz, synthesized by him in 1927. It was named "uroselectan" by von Lichtenberg after its administration to patients had proved successful. The drug was then applied to a larger number of patients, under the direction of von Lichtenberg, and the work progressed sufficiently to permit of Swick presenting his work at the Urologic Congress in Munich in October, 1929. This work was published in the *Klinische Wochenschrift* (**8**:2087, 1929). Von Lichtenberg at the same meeting read a paper on its clinical application (*Klinische Wochenschrift* **8**:2089 [Nov. 5] 1929).

In the meantime, Roseno, at the German Surgical Congress, which met in April, 1929, reported having obtained successful roentgenograms after intravenous injection of sodium iodide and urea. In the hands of some, however, this substance was reported often to be associated with reactions too severe to permit of its general use.

When Swick returned to America, he reported his work before the Section on Genito-Urinary Surgery of the New York Academy of Medicine, Jan. 15, 1930, and published his paper in the *American Journal of Surgery* in February. After this, and before the drug was placed on sale in the United States, it was arranged by von Lichtenberg, through Alexander Randall, secretary of the American Urological Association, to have it distributed to twelve different clinics, gratis. Those who had used the material reported their results at the meeting of the American Urological Association in New York in June. These reports were followed by a consideration of its clinical application by von Lichtenberg and a report on the chemistry of the drug by Binz. Previous to this meeting, von Lichtenberg had demonstrated its clinical value by its use in about 700 cases.

The technic of administration is as follows: The preparation, which is a powder, is prepared for use by dissolving 40 Gm. in 100 cc. of sterile distilled water. This is twice filtered and is sterilized by autoclave, or water bath, as any solution for intravenous injection. The material is supposed to contain 42 per cent of iodine and it has left the circulation four hours after injection in cases in which renal function is good.

Administration is intravenous and is given with the solution at body temperature at the time of injection. The patient's face immediately becomes flushed, and tachycardia and palpitation occur. Patients experience a feeling of general warmth, and in more than half of the cases they complain of pain in the arm, near the shoulder, which they describe as a feeling that the arm is bursting. There is usually considerable dryness of the throat, and thirst, but water is withheld in order that the drug may be secreted in concentrated form. These symptoms usually pass off within ten minutes. Occasionally nausea and vomiting take place, and urticaria has been observed. Symptoms resembling acute iodism, manifested by lacrimation, sneezing and dyspnea, have occurred, but such reactions always have been transitory and delayed reactions never have been observed. After ten minutes from the onset of injection, untoward symptoms never have developed.

Roentgenograms are taken from fifteen to twenty minutes after injection, and again from thirty to forty minutes after the first roentgenogram. Before the second roentgenogram is taken, the bladder is emptied, in order that the shadow of the drug in the bladder will not obscure the lower parts of the ureters. If the first plates show that but little of the drug has been secreted, it is presumed that the kidneys are functioning poorly, and several hours should be allowed to elapse, during which plates should be made at intervals. Impairment of renal function will allow but poor concentration of the drug in the bladder and practically none in the kidney; many hours are required for its secretion.

This fact led Swick to develop a gravimetric method of determining renal function which can be applied to urine from each kidney separately if the ureters are catheterized but which is of more general application when used with urine from the bladder to indicate the function of the two kidneys together. This method as yet has not received sufficient clinical application for its worth to be determined.

The greatest field of usefulness for sodium 2-oxo-5-iodo-pyridine-N-acetate is in those cases in which the fact of the presence or absence of a second kidney is in doubt because only one ureter can be found by cystoscopic examination, or because retrograde injection of the ureter is prevented by stone or stricture. In such a case if the kidney on one side becomes visualized after intravenous injection of sodium 2-oxo-5-iodo-pyridine-N-acetate, and a pelvic outline is not seen on the other side, one is reasonably sure of the absence or of the extremely poor function of the kidney on the latter side.

Good visualization occurs, not only as a result of good renal function but also secondarily to urinary retention. Therefore, a dilated renal pelvis or ureter usually will be well outlined, although the function may be greatly impaired as the result of retention of the drug. This fact lessens considerably the usefulness of the drug in determining renal function by visualization. Its usefulness is lessened also by the fact that, in many apparently normal cases, visualization of the renal pelvis is poor; this is hard to explain, for a similar case in which injection is done with the same technic visualization may be good. Undoubtedly much improvement will be noted in the drug and its application in the course of the next few years.

As a substance for injection into the renal pelvis through the ureteral catheter, for purposes of pyelography, sodium 2-oxo-5-iodo-pyridine-N-acetate in the same dilution as that used for intravenous injection has proved the best material yet developed and seems certain to replace sodium iodide, as the latter replaced thorium compounds. Because sodium 2-oxo-5-iodo-pyridine-N-acetate is free from toxic effect, bilateral pyelograms can be made. If pyelovenous backflow occurs, the drug does not cause bodily reaction, and if retention in a hydronephrotic sac is discovered, irritation such as that which resulted from sodium iodide does not occur.

The drug has been used in America now for a sufficiently long period to allow of the assertion that its application is not followed by any alarming sequelae. Delayed manifestations need not be expected.

SUMMARY

As a substance for injection through the ureteral catheter, sodium 2-oxo-5-iodo-pyridine-N-acetate is the best material so far obtained; used intravenously, it often helps in the diagnosis when ureteral catheterization is impossible; however, it is not secreted in the same concentration by all kidneys of apparently equal function and hence is at times disappointing; as a substance for renal functional test, its worth is not yet proved.

PRELIMINARY REPORT OF THE COUNCIL

The Council has authorized publication of the following preliminary report. W. A. Puckner, Secretary.

AVERTIN

Avertin was submitted to the Council in February of the present year for its consideration.

The Council recognizes the fact that Avertin presents certain desirable properties but definite action concerning its recognition was postponed pending the result of investigations of certain of its side actions now being conducted. For the information of the medical profession the Council submits the following report concerning the present status of the drug:

Avertin is tribrom-ethanol, $CBr_3.CH_2OH$, a white crystalline substance. It was introduced in Germany by Willstaedter and Duisberg in the summer of 1926, to be used alone for rectal anesthesia or to be supplemented by other narcotics, including morphine and ether. It was supplied to a number of clinics, in which it was used experimentally. A superficial pharmacologic study of Eichholtz made in the laboratory of the manufacturers, and a clinical report by Butzengeiger were presented at the German Surgical Congress at Berlin in April, 1927. At that meeting Sauerbrook reported three deaths; Reischauer three; Melzner four; Druegg two; and Sievers one death, though Avertin is not blamed by them for all of these deaths. Following the severe criticism of Avertin by numerous surgeons at the meeting of the congress, it was temporarily withdrawn by the manufacturers.

The powder is soluble in about 30 parts of water at 40 C., but the aqueous solution is prone to decomposition, and some of the accidents attending its use were attributed to the decomposition products. The manufacturers claim to have overcome this tendency to decomposition by marketing Avertin in the form of a solution of which 1 cc. contains 1 Gm. of Avertin dissolved in amylene hydrate (tertiary amyl alcohol). The amount of amylene hydrate is not stated. This preparation was marketed in 1927 and has been the subject of several hundred reports. The testimony concerning Avertin is so conflicting that it is impossible at the present time to know precisely where to draw the line concerning its advantages and its disadvantages. This is especially true concerning its contraindications, about which there is no agreement, nor is there even an approach to an agreement concerning the proper dosage or the technic of using it in any of a great number of different procedures.

Avertin depresses the respiratory center, lessening both frequency and volume; it depresses the vasomotor center, causing a fall of blood pressure. The depression of the respiratory center is the more pronounced; but when it coincides with the depression of the vasomotor center, it increases the danger, especially when it is used with morphine and other accessory narcotics. Killian states that Avertin acts on the liver like chloroform. In 1928 he analyzed a number of reports of deaths from Avertin and concluded that Avertin injures the respiratory center more than chloroform or ether narcosis of equal depth. Killian severely criticizes Melzner, stating that the larger surgical clinics in general take a cautious attitude, some warning against it and some wholly denying its use. He reported that the drug had been tested with little discrimination by about one hundred surgeons, whose reports are often fragmentary and do not show precautions necessary for careful examination (Loewe, a pharmacologist, also reported adversely on Avertin). It may be added that the greater number of the reports up to the present time are of this character. Schwalbe in 1927 enumerated some twenty surgical and gynecologic clinics which refused to use Avertin on the basis of available reports or, having used it for a time, gave it up; and he also mentions ten clinics in which its use was given up or much limited on account of serious accidents. However, many other surgical and women's clinics have reported better results. Aside from the depression of the respiratory center and the vasomotor center, and the probable occasional injury to the liver, the principal objection to Avertin lies in the fact that anesthesia induced by it is not under control. This applies partially to so-called basis narcosis (also referred to as "basal anesthesia"), to which the manufacturers themselves are now inclined to restrict Avertin, apparently recognizing the dangers of complete narcosis with it. The manufacturers claim that amylene hydrate stimulates the respiratory center, thereby implying that this materially adds to the safety of Avertin. Few studies of amylene hydrate have been made, but Harnack and Meyer reported that the respiration is at first increased in rate and depth, and then gradually weakened up to paralysis of the respiratory center. They also reported that the blood pressure sinks slowly up to the point of death in mammals, that it paralyzes all parts of the central nervous system successively like alcohol, and that it paralyzes the heart muscle in the frog. In view of the work of Harnack and Meyer, which has not been disputed, it is misleading to maintain that amylene hydrate stimulates the respiration.

The advantages claimed for Avertin liquid include: 1. Absence of so-called psychic shock or mental distress (almost unanimous). 2. Absence of irritation of the respiratory tract with less postoperative bronchitis and pneumonia. 3. Absence of direct injurious action on the heart, kidneys or other organs, with the possible exception of the liver. 4. Convenience for operations about the face, especially when a cautery must be used. 5. Usefulness in long operations when deep anesthesia is not necessary. 6. Less frequent vomiting than after ether or chloroform. 7. Lasting sleep after operation, frequently making it unnecessary to use morphine for the relief of postoperative pain. 8. Amnesia. 9. Absence of injury after repeated administration (as in tetanus). 10. Rapid elimination (implying less toxic action). (It should be understood that publications concerning "Avertin" refer in part to Avertin alone, and in part to Avertin liquid containing amylene hydrate.) The disadvantages include: 1. Higher death rate than after ether. 2. Depression of respiratory center. 3. Depression of circulation. 4. Acidosis as actively as after chloroform. 5. Insufficient muscular relaxation in laparotomy (?). 6. Falling back of tongue, making constant observation necessary until the patient is fully conscious. 7. Lack of control from moment to moment (almost unanimous). 8. Want of exact dosage. 9. Narrow zone between anesthetic and fatal dose. 10. Disadvantages inherent in mixed narcosis. 11. Lack of adequate pharmacologic study of Avertin and its synergistic action with morphine, ether and other substances. 12. A lack of agreement concerning the indications and contraindications.

A preliminary report such as this can hardly be more than suggestive in view of the almost innumerable problems that are involved; but the foregoing presents the evidence concerning the drug which is at the present time available to the Council. Though the present evidence indicates that Avertin may prove valuable as a means of initiating narcosis (so-called basis narcosis) but not for complete narcosis, the Council decided not to admit the drug to New and Nonofficial Remedies: (1) until satisfactory studies of its properties, its advantages and its disadvantages have been made; (2) until the contraindications have been satisfactorily established; (3) until a generally accepted technic whereby it can be used as satisfactorily as ether has been established; (4) until the action of the amylene hydrate in Avertin liquid—whether by addition or by potentiation—has been determined and the amount declared; and (5) until the advertising has been revised to omit misleading statements contained in the present advertising and especially to recommend the product only for initiation of narcosis (basis narcosis) and not for complete narcosis.

AGRANULOCYTIC ANGINA

The first reference to agranulocytic angina seems to have been made in 1907, when Turk[1] called attention to the low granulocyte count in some cases of severe sepsis. The suggestion apparently did not arouse interest until 1922, when Schultz[2] described a number of cases which revealed an almost complete absence of granular cells associated with a group of symptoms and pathologic conditions which he declared formed a clinical entity. Later Friedemann[3] named this group of cases "agranulocytic angina." The features emphasized by Schultz were a high fever, occurring generally in elderly women with necrotic throat infections, rapid exhaustion, slight jaundice frequently, leukopenia with few if any granular cells but no involvement of the red blood cells or platelets, and death within a short time in almost every case. After Schultz's work became known, case reports began to appear in medical literature everywhere; now more than 150 cases have been recorded. In 1927, Kastlin[4] collected reports of forty-three cases and reported two more, with only three recoveries, a mortality of 93 per cent. Stomatitis was always present in these cases, necrotic ulcers occurring in the mouth, larynx or esophagus. Petechial hemorrhages were found in twelve cases at necropsy. In some of these cases there were high platelet counts but in others the counts were low. Nonreactive ulcers were found in the gastro-intestinal tract and in the female reproductive system. Because of the variations in the cases reported, Kastlin believes that agranulocytic angina is not a clinical entity. Moreover, numerous cases have been reported that vary even further from the original description. In some cases only a sore throat without ulceration, and the typical lack of granulocytes, are the diagnostic symptoms. Several investigators report an ulcer in the rectum or vagina without involvement of the throat, the clinical picture being otherwise the same. Blumer[5] reports a case beginning with numerous boils that became large abscesses, with the blood and the clinical course essentially the same as in the cases described by Schultz. Harkins[6] reports eight cases, four of which he considers to be agranulocytic angina and the other four of which he calls granulocytopenia. He classes one case as granulocytopenia because of the anemia and evidences of hemorrhagic diathesis, although it answers Schultz's description otherwise. Blanton[7] reports a case which he calls agranulocytic angina in which there was a staphylococcus abscess in the neck. One abnormally low granulocyte count was found and, after incision of the abscess, the count promptly returned to normal the next day. Farley[8] has collected reports of a series of cases following arsphenamine therapy, which had an agranulocytic period. It is clear that there may be a variety of conditions associated with the low granulocyte count. Obviously, they cannot all be called agranulocytic angina. Schultz's description would eliminate a number of cases which, except for the location of the ulcer, seem to have the same basis. Stocké[9] divides the cases into three different groups, one group answering Schultz's description, a second showing the presence of anemia, and the third evincing a tendency to hemorrhage. The name agranulocytosis, first used by Schultz, has been used by some as synonymous with agranulocytic angina and by others for differentiation. Only one condition appears common to all these cases, namely, the lack of granulocytes; therefore agranulocytosis or granulocytopenia would seem the most suitable name. While some cases may seem to fall into definite groups, so many cannot be classified that it would be too arbitrary to justify separation until other factors are discovered that will more distinctly differentiate the various types of cases.

Bacteriologic study has not yet given any clear-cut results. There are reports of a number of positive blood cultures, but the variety of organisms found has only added to the confusion. The organisms are, for the most part, various types of staphylococci and streptococci. Friedemann isolated *Bacillus pyocyaneus* from the blood stream once. Lovett[10] found the same organism in the throat and determined that the isolated organism caused a relative lowering of the granulocyte count in rabbits. Dasse[11] also found the organism in the throat in almost pure culture and verified Lovett's animal experiments. The blood cultures were negative in both cases. Vincent's organism frequently has been isolated from the throat, Harkins reporting it in five of his cases. Arsphenamine was used in several of his cases without apparent ill effects. Yet Farley's cases seemed to be due to the use of arsphenamine. Other throat cultures have shown a large variety of organisms that have been regarded as secondary invaders. In some cases in which a blood count has been taken early, a lack of granulocytes was found before the ulcerations appeared. Roberts and Kracke's[12] patient showed only 10 per cent granulocytes seventy-two hours before and no granulocytes the last twenty-four hours before she became ill. Cultures of the bone marrow have been taken by some workers but organisms were not found. The cases reported are endemic in character and there is no evidence of transmission by direct contact. One of the cases reported by Harkins as agranulocytic angina followed extraction of an abscessed tooth, a second case followed an abscess in the neck after tooth extraction, while a third case began one week after tonsillectomy. These, as well as other reports, indicate that some slight infection may in certain people precipitate the illness. Harkins finds reports of at least six cases presenting an abnormal granulocyte count prior to the onset of the illness.

Is granulocytopenia a new disease or were cases not recognized or reported before Schultz's description? Harkins has collected reports of about 150 cases from the literature with a mortality of 82 per cent. Reports indicate that patients without necrotic ulcers recover more frequently, which helps to account for his lower mortality. The reports also indicate that the ultimate prognosis of patients who recover may not be so good. There are at least five cases on record in which the patient seemingly recovered only to succumb to another attack in an interval of from three months to two years. All cases of agranulocytic angina should be studied exhaustively both clinically and bacteriologically if anything is to be known about the etiology. Lovett's work should be extended and attempts should be made to see whether a definite syndrome can be produced experimentally. At present it would seem that agranulocytic angina or, better, granulocytopenia is not a definite clinical entity but represents an indefinite group of cases resulting from some injury to the granulopoietic mechanism.

THE SEARCH FOR HEALTH

One of the most widely discussed addresses among the varied communications presented at the recent meeting of the British Medical Association at Winnipeg was the lecture of the distinguished English physician Dr. Robert Hutchison on "Mankind's Pursuit of Health." Starting with the thesis of G. K. Chesterton that "of all human things the search for health is the most unhealthy," he ventured the suggestion, perhaps ironically, that the old ignorance about the body and stolid resignation to its ills was probably a more "healthy" attitude, and certainly a happier one, than the modern curiosity and overanxiety.

Many physicians may read these pronouncements with mingled emotions. They doubtless agree with the arraignment of that overanxiety which develops hypochondriasis in regard to bodily well being and approve the censure of the numerous fads that are lauded by single track minds as the secrets of securing perfect health. Many of Dr. Hutchison's auditors and readers, however, wonder whether the laudation of a single universally applicable rule of health—moderation, the old universal secret of health—does not involve a condemnation of the choicest efforts of modern personal hygiene. The ridicule of calories and vitamins, of whole wheat and golf and "better baby" campaigns and what not sounds familiar enough. It is easy to make an audience laugh; but what is created out of the débris of destructive criticism is not infrequently almost as fatuous as some of the things that are assailed. Both the revolutionist and the reactionary deal as a rule with extremes of statement. They fail to recognize the middle course that sanity dictates.

Let us examine a few instances. Dr. Hutchison warned his hearers:

> Likes and dislikes should be listened to; they are nature's indications of what probably agrees or disagrees. As to "calories," our appetite was given us to tell us how much food we need and in health is usually a trustworthy guide. Leave raw vegetables, except salads, to the herbivorous animals and let the vitamins look after themselves.

Such advice would admittedly be sound if all of us were living in a garden of paradise where all of the earth's choicest dietary offerings were at our command. Unfortunately, the satisfaction of the demands of man is all too often limited by geographic, regional, climatic and particularly economic factors. War has taught us what all this may mean. The praise of appetite as a sole safe guide in all matters of diet overlooks the drunkard and the glutton. One may sympathize with the undue propaganda of exercise for health and counsel moderation; but is there a human instinct for "careful living"?

The country's greatest need was once described as a good five cent cigar. The summum bonum of the well reared person is described by our British colleague as character. "A country's greatest asset is character. Let us therefore cultivate character and let health look after itself, being assured that to a nation made up of men and women of character, all things, health included, will be added." Nothing is said about the effect of health on character; but one might venture a sally as to modifications that arthritis or hay-fever or perennial colitis might impose on it.

Science has been described as organized common sense. Shifting as the tenets of science may be, they nevertheless have made worth-while contributions. Calories have saved more than one deserving life; and vitamins have banished much human distress. The realm of scientific progress has given much that may be profitably promoted without detriment to character and with the occasional enjoyment spelled by good health.

THE BODY FLUIDS AND BURNS

The importance of the body fluids was recognized by Celsus something like twenty centuries ago. Yet it is within the lifetime of most practicing physicians of today that administration of fluid for its own sake has become a widespread life-saving measure. The reason that general recognition of this factor in treatment has been comparatively recent is probably that chemical methods were necessary before studies of metabolism could be exact and that investigations of water metabolism were consequently delayed. Rubner in Europe and Rowntree[1] in this country have given great impetus to investigation of the subject last mentioned. For the most part, the indications for restoration of lost fluids are well known. However, the rationale of the introduction of fluids in cases of burn, as recently emphasized by Underhill[2] and by Bancroft[3] is not so widely recognized.

Just as other injuries cause shock, so does a burn; but a condition of anhydremia also results, and this is of great significance, writes Underhill. If a burn involves one sixth of the surface area of the skin, the loss of fluid in twenty-four hours may equal 70 per cent of the total blood volume. Since Rubner has shown that in starvation an animal can live after loss of nearly all its glycogen and fat, half of its protein, and nearly half of its body weight, but that it dies from loss of one fifth of its water,[1] the fatal influence of the great loss in burns is apparent. With such depletion the blood becomes concentrated, the circulation slowed, and the blood loses oxygen. Partial asphyxiation results, metabolic processes become altered, the heat-regulating mechanism becomes impaired, the temperature falls, and vital activities are suspended. In the treatment of a burned patient, therefore, the burn itself is relatively unimportant at first. Even the clothing should not be removed. Attention to the all-important systemic effects of the injury should embrace, besides the usual measures against pain and fall in temperature, immediate intravenous administration of 1,000 cc. of physiologic solution of sodium chloride at a rate not greater than 25 cc. a minute. Thereafter fluid, particularly physiologic solution of sodium chloride, should be introduced by every available channel, in the amount of from 4 to 8 liters in twenty-four hours, until the capillaries have lost their abnormal permeability, fluids are retained, and the concentration of hemoglobin and of chlorides in the blood approach normal. Usually the critical period has passed in from twenty-four to forty-eight hours. Underhill is not concerned with toxemia. He doubts the existence of a specific burn toxin, and he has not seen symptoms of intoxication develop if his method of treatment has been employed.

Bancroft's treatment of shock is in general similar to Underhill's, including administration of fluid. However, he believes that toxemia is an important element and that whereas those patients who die within forty-eight hours succumb to shock, those who die in the period between forty-eight hours and three weeks are overwhelmed by toxemia. After the period of shock, therefore, his use of solution of sodium chloride is directed against toxemia and toward the maintenance of body fluids and blood chlorides. When the onset of toxemia is signalized by vomiting, he gives from 2 to 3 liters of "saline solution" a day; with marked vomiting, from 500 to 1,000 cc. of 2 per cent solution of sodium chloride subcutaneously, or 500 cc. of 3 per cent intravenously, very slowly.

Both authorities administer solution of sodium chloride within the first forty-eight hours after an extensive burn, and both administer it thereafter if necessary, although their reasons for doing so do not coincide in all respects. The important feature would seem to be that both place great reliance on the maintenance of body fluids and blood chlorides and that both are successful. Cases of burn, therefore, seem to be another field in which administration of solution of sodium chloride may be the means of saving life.

Current Comment

NONVOLATILE SUBSTANCES AS ANESTHETICS

Recently the Council on Pharmacy and Chemistry announced the acceptance of a barbital derivative for oral and rectal use as a preliminary to surgical anesthesia. Experimentally this product has also been administered intravenously as a means of inducing complete anesthesia or for partial anesthesia (to be completed by administration of a volatile anesthetic), and a considerable number of reports of such experimentation have been published. Such intravenous use is, however, far from safe; the Council therefore accepted the product only for oral or rectal use as a preliminary to surgical anesthesia. The manufacturer is not marketing the product for intravenous use. In this issue of The Journal appears a preliminary report of the Council on Avertin, which is tribromethanol. This substance has been proposed not only for initiating anesthesia but also as the chief means of inducing unconsciousness, to be supplemented when necessary by a small amount of an inhalation or local anesthetic. The Council concludes from a review of the evidence that Avertin may prove valuable as a means of initiating narcosis but that it is not proved to be a safe agent for complete narcosis, either by itself or combined with a volatile anesthetic. The Council holds that further study of the product is necessary. These two products illustrate a modern tendency in anesthetics set forth in the abstract of an article by Lendle[1] appearing also in this issue of The Journal. This tendency is represented by the effort to find a nonvolatile agent for complete narcosis or, failing that, a nonvolatile agent to serve for so-called basal anesthesia, supplemented by the use of a volatile anesthetic. Lendle's paper seems to show that neither Avertin nor the barbital derivative "Pernocton" is a satisfactory solution of the problem. Safe and efficacious new methods of anesthesia may result from the modern work in this field; but all the evidence indicates that the products thus far proposed for so-called basal anesthesia are hypnotics or sedatives and should be used as such. They cannot be safely used for complete anesthesia and can be safely used in combination with other agents for the production of complete anesthesia only by those thoroughly experienced in the administration of anesthetics and closely familiar with the studies of the use of nonvolatile agents for anesthesia. Thus far their intravenous use must be considered unsafe.

PULMONARY ASBESTOSIS

In 1928 The Journal,[1] commenting on an article by W. E. Cooke,[2] suggested that pulmonary asbestosis, because of its dangers and its unique pathologic features, deserved more attention than had been accorded it. Two and a half years later Mills[3] reported the first case from the United States. His patient had worked in an asbestos mine in South America prior to 1898, had returned to the United States, and again had been employed in South America, this time in an unstated occupation, between 1911 and 1913. He died in Minnesota in 1929. The history of the case indicates that the asbestos which was found in the subject's lungs at necropsy was inhaled prior to 1898. If so, the profound pulmonary changes which evidently were induced by the asbestos, and which seemingly contributed to the patient's death, were present thirty-two years after the agent that caused them was introduced. Even if the exposure to the asbestos occurred at the time of the patient's later visit to South America, the pulmonary injury endured at least seventeen years. Accordingly, Mills has concluded that pulmonary asbestosis is an incurable disease, from which the patient may or may not die. The cause of death, if tuberculosis is avoided, seems to be pulmonary fibrosis with its indirect effect on the heart. At necropsy of Cook's patient, pulmonary fibrosis and evidence of extensive tuberculosis were found; it was not certain whether the fibrosis was due more to the tuberculosis or to the asbestosis. In Mills's case, evidence of tuberculosis was not found but the fibrosis was severe. The conjecture seems warranted, therefore, that asbestos is capable of producing two types of injury, somewhat as iron dust is capable of producing two types of pulmonary siderosis. According to Bohrod,[4] who cited the work of Hart, the red type of iron lung is found in persons who work in iron mines and in factories using certain iron pigments; pneumonoconiotic induration predominates and there is little tuberculosis. Metal grinders and polishers display the black type of iron lung; induration is less evident and tuberculosis is unrestrained. That siderosis and asbestosis are allied seems likely in view of the evidence that the iron-containing[1] portions of asbestos constitute the danger to health in the asbestos industry. Concerning the relation of physicians of the United States to this industry, Mills pointed out that asbestos is mined and manufactured in many parts of this country and that pulmonary asbestosis surely will be encountered. In England the workmen's compensation act has recently been extended to include this condition.[5]

INSENSIBLE PERSPIRATION AND BASAL METABOLISM

The estimation of basal metabolism has proved to be unexpectedly valuable as a diagnostic aid. The measurements of the respiratory exchange, which are now depended on to furnish the requisite information, have been greatly simplified in recent years, so that the procedure can be made applicable even in the office of the individual practitioner. There are, however, refinements of technic that ought to be applied more widely than they usually are. This refers particularly to the proper preparation of the patient and to the maintenance of strictly "basal" conditions. In the case of infants and children, obvious difficulties present themselves in the measurement of respiratory exchange as well as in direct estimations of heat output. Fortunately an alternative procedure has been proposed in the relatively simple method of ascertaining the insensible losses represented by perspiration. The determination of loss by insensible perspiration as an index of metabolism was discussed in detail in 1926 by Benedict and Root[6] in its application to adults. Its use in relation to children has been championed by S. Z. Levine and his co-workers[7] in the Department of Pediatrics of the Cornell University Medical College, New York. Basal standards of insensible perspiration were proposed by these workers in reference to the normal infant. The latest researches of Levine and Marples[8] have been concerned with the validity of the proposed methods and their basis of reference to predictions. A statistical study was made of the published data responsible for the standards at present available for the basal metabolism and basal insensible perspiration of normal infants. The investigation included consideration of the correlation between the two variables in simultaneous calorimetric measurements as well as in independent measurements with the respiration chamber and the balance. The evidence secured points to a high positive correlation between the physiologic mechanisms of heat production and insensible perspiration in the human subject.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10:15 on Tuesday, and 10 on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

November 10.	Physical Education.
November 11.	Eugene Field Poem.
November 15.	Raising Cain.

Five Minute Health Talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

November 10.	Where Do People Die?
November 11.	In Flanders' Fields — Heroes of Medicine.
November 12.	The Cigaret Causes a Stir.
November 13.	Music in Medicine.
November 14.	Music in Medicine.
November 15.	Music in Medicine.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

COLORADO

Society News.—The Larimer County Medical Society was addressed, October 1, by Dr. James A. Matlack, Longmont, on "Publicity for the Physician," and by Dr. Magnus J. Stewart, Loveland, on "Aviation Eye Tests."——The Medical Society of the City and County of Denver was addressed, October 21, by Dr. Earl J. Perkins, Denver, on "Difficulties in Varicose Vein Injections."——Dr. Alfred H. Washburn has assumed the position of full-time director of the child research council of the University of Colorado School of Medicine and Hospitals.

CONNECTICUT

Society News.—The New Haven County Medical Society held its one hundred and forty-seventh semiannual meeting at Waterbury, October 23. Addresses were given by Drs. William H. Morriss, Wallingford, on "Value of Blood Cell Study in Pulmonary Tuberculosis," and William H. Glafke, New York, "Some Mechanical Factors in the Treatment of Digestive Disorders." The speaker at the dinner was Charles S. Clark, dean of the Yale Law School, on "Can Law Be Scientific?"

Dr. Rappleye Appointed Professor of Medical Economics.—Dr. Willard C. Rappleye, New Haven, has been made associate professor of medical economics at Harvard University School of Public Health for five years from February 1. Dr. Rappleye has been director of studies of the Commission on Medical Education, New Haven, since 1925, and previous to accepting this position had been professor of hospital administration at Yale University and director of the New Haven Hospital.

Dr. Fulton Appointed Professor of Physiology.—Dr. John Farquhar Fulton was recently appointed Sterling professor of physiology and head of the physiology department at Yale. Dr. Fulton is a graduate of Harvard and Oxford universities. He was awarded the Warren Triennial Prize by the Massachusetts General Hospital in 1925, then returned to Oxford as a fellow, where he conducted research on the central nervous system. Dr. Fulton is well known for his report on "Muscular Contraction and the Reflex Control of Movement." At Yale he will be particularly concerned with studies of personality in the Institute of Human Relations, where he will be associated with Drs. Joannes G. Dusser de Barenne and Eugen Kahn, Sterling professors of physiology and psychiatry, respectively.

DELAWARE

State Medical Meeting and Election.—At the one hundred and forty-first annual session of the Medical Society of Delaware, October 14-15, at Dover, the program included papers by Drs. Gottfried Metzler, Jr., Bridgeville, on "Treatment and Prognosis of Abortion"; Carl B. Scull, Jr., Dover, "Exfoliative Dermatitis Following Use of Heavy Metals in Treatment of Syphilis"; Mark B. Holzman, Wilmington, "Value of Proper Diet in Prevention of Disease"; Samuel D. Earhart, Wilmington, "Differential Blood Count"; Arthur M. Shipley, Baltimore, "Suppurations Within the Chest"; John H. Stokes, Philadelphia, "Prevention of Infectious Transmission of Syphilis," and William F. Rienhoff, Jr., Baltimore, "Operative Treatment of Duodenal and Gastric Ulcer." Dr. Isaac J. MacCollum, Wyoming, delivered the presidential address. Dr. William Gerry Morgan, Washington, D. C., president, American Medical Association, gave an address. Dr. George C. McElfatrick, Wilmington, was elected president of the association, and Dr. William O. LaMotte, Wilmington, was reelected secretary. The next annual session will be held at Wilmington, Oct. 13, 1931.

GEORGIA

Society News.—The Fulton County Medical Society was addressed, October 16, by Dr. James L. Campbell on "A Clinical Study of Diseases of the Mammary Gland"; Dr. Bernard McH. Cline gave a clinical talk, illustrated, on "Endoscopy Under Local Anesthesia"; Dr. Rudolph A. Bartholomew presented a case report on "Pregnancy Complicated by Congenital Absence of Left Diaphragm."——The Second District Medical Society was addressed at Cairo, October 10, among others by Dr. George H. Noble, Atlanta, on "Cutting of Flaps in Amputation of Mammary Gland with View of Preventing Necessity of Skin Graft and Preserving Full Range of Arm Motion."——Dr. Samuel J. Sinkoe, Atlanta, addressed the Eleventh District Medical Society at Quitman on "Hematuria and Longevity," and Dr. Allen H. Bunce on diagnosis of abdominal conditions.

IOWA

Personal.—Dr. Wallace S. Petty, Sioux City, has been selected as director of the Woodbury County Health Unit; he has been director of cooperative health work with the Missouri State Department of Health. Woodbury County was the second unit in Iowa to adopt the full-time county health unit plan as provided under the permissive county health law. A total of $37,200 has been made available in Woodbury County for the establishment of a county health unit. It will be supervised by Dr. Erval R. Coffey of the federal public health service. The organization will cooperate with and supervise existing health and charity organizations in Sioux City and Woodbury County.——Dr. Daniel C. Steelsmith, who has been acting commissioner of health since the death of Dr. Henry Albert, was recently appointed state commissioner of health.

Society News.—Dr. Joseph C. Bloodgood, Baltimore, delivered a public lecture on cancer in Des Moines, October 17.——At a recent meeting of the Washington County Medical Society, Dr. Emmett T. Wickham, Washington, president, proposed the organization of a library for the use of members, and donated his private medical library.——The seventy-seventh annual meeting of the Dubuque County Medical Society was addressed, September 23, in Dubuque, among others by Drs. Nelson M. Percy, Chicago, on "Appendicitis and Intestinal Obstruction"; Clarence W. Baldridge, Iowa City, "Recent Development in Diseases of the Blood," and David A. Horner, Chicago, presented motion pictures on "Management of Breech Presentation."——Dr. John W. Kime, Fort Dodge, addressed the Hardin County Medical Society in Ackley, September 18, on "Light in Therapeutics."——The Polk County Medical Society was addressed, September 30, by Dr. Richard H. Jaffe, Chicago, on "Visceral Changes in Late Stages of Acquired Syphilis, with Special Reference to Syphilitic Aortitis."——Dr. Eugene F. Talbott, Grinnell, addressed the Poweshiek County Medical Society, September 18, on the thyroid gland.——The Des Moines Academy of Medicine and the Polk County Medical Society were addressed, October 28, by Drs. Walter D. Abbott and Lee Forrest Hill, both of Des Moines, on "Surgical Relief of Intractable Pain" and "Splenectomy in Children," respectively; the societies will be addressed, November 14, by Dr. Jay Arthur Myers, Minneapolis, on "Tuberculosis Among Children."——"Modern Treatment of Goiter" was the subject of Dr. Christian B. Luginbuhl, Des Moines, before the Audubon County Medical Society, October 2, and "Childhood Tuberculosis" that of Dr. John H. Peck, Des Moines.

MICHIGAN

State Section on Dermatology and Syphilology.—Dr. Cyril K. Valade, Detroit, has been selected by the executive committee of the council of the state medical society as the first chairman of the newly created section on dermatology and syphilology. Dr. Valade is president of the Detroit Dermatological Society.

Society News.—Dr. Edward L. Keyes, New York, addressed a joint meeting of the Wayne County Medical Society with the Detroit Urological Society, October 21, on "Preventable Diseases in the Treatment of Prostatism."——Dr. Frederic Schreiber, Detroit, addressed the Wayne County Medical Society, October 28, on "Encephalography as an Aid in the Diagnosis of Brain Lesions."——The Oakland County Medical Society was addressed, October 16, by Dr. Loren W. Shaffer, Detroit, on common skin diseases.——Dr. Frank C. Yeomans, New York, will address the Academy of Surgery of Detroit, November 13, on treatment of carcinoma of the rectum and sigmoid.

University Society Meeting.—The University of Michigan Pediatric and Infectious Disease Society will hold a meeting, November 14-15, at the University Hospital, Ann Arbor. "Abdominal Pain" will be discussed by Drs. William D. Lyon, Akron, Ohio, and Thomas D. Gordon, Grand Rapids; "Nutritional Anemias" by Luvern Hays and Raphael Isaacs, Ann Arbor, and "Mental Hygiene" by Theophile Raphael, Robert R. Dieterle, Louis Schwartz and Willard C. Olson, Ph.D. Among others on the program will be Drs. Floyd H. Lashmet, Ann Arbor, "Tests of Kidney Function"; Raymond W. Waggoner, Ann Arbor, "Chorea," and Malcolm H. Soule, Sc.D., Ann Arbor, "Agglutination Reactions."

Internship Required by State Board.—The Michigan State Board of Registration in Medicine has recently issued a curriculum of intern work. The board requires that each candidate for a Michigan license must present a certified statement from an approved hospital that he has satisfactorily completed this curriculum of work during twelve months serving as an intern. Each hospital is to provide during the twelve months of residency of each intern six months' service in medicine and six months in surgery. He must report at a general staff meeting on either a study of any group of hospital cases or a report of research work done in the hospital. The intern is subject to a personal rating as well as a rating on history writing. The chief of staff of the hospital must certify in writing to the board that the intern has conformed to the schedule.

MINNESOTA

Supreme Court Upholds Basic Science Law.—The constitutionality of the basic science law was upheld by the Minnesota Supreme Court in the case of the *State of Minnesota v. Broden.* The defendant, an unlicensed healer, was arrested in Duluth in December, 1929, charged with practicing the healing art without a basic science certificate. He demurred to the information filed against him on the ground that the basic science law was unconstitutional. The demurrer was overruled and he appealed to the supreme court. The court, October 10, rendered a decision holding that the law does not violate any constitutional provision, either state or federal. This is the first time that a state supreme court has passed on the validity of a basic science law. Defendant Broden will now have to stand trial on the charges against him.

MISSOURI

Survey of Bottled Water.—The division of public health engineering and sanitation has started a survey of all bottled water supplies in the state. This will include a sanitary survey of the source of water sold in containers, method of handling, and bacteriologic analyses of samples. The survey is being made as a preliminary step to enforce state board of health regulations governing bottled supplies.

Society News.—Drs. George Wilse Robinson, Jr., and Elmer D. Twyman, *Kansas City, addressed the Jackson* County Medical Society, October 21, on "Use of Glucose Solution Intravenously in Neuropsychiatric Diseases" and "Surgical Treatment of Accessible Cancer," respectively.——The St. Louis Trudeau Club was addressed, October 2, by Drs. James L. Mudd on "Chest Surgery on the Continent" and Howard H. Bell on "Present Status of Calmette's B C G Vaccine for Tuberculosis."——Dr. Oscar Monroe Gilbert, Boulder, Colo., addressed the Jackson County Medical Society, October 18, on "Progress in the Management of Tuberculosis."

NEBRASKA

Society News.—The tenth annual meeting of the Seventh Councilor District Medical Society was addressed at Hebron, October 23, by Drs. William I. McFarland, Hebron, on "Treatment of Established Infection"; George W. Ainlay, Fairbury, "Fevers of Infancy and Childhood of Idiopathic Origin"; Charles G. McMahon, Superior, "Suture of Musculospiral Nerve," with case report; James E. M. Thomson, Lincoln, "Simple Therapeutic Procedures Applied to Certain Major Fractures"; Wesley C. Becker, Lincoln, "Treatment of Puerperal Sepsis"; Alexander A. Conrad, Crete; Eugene C. Foote, Hastings, "A Visit to India and Other Foreign Countries," with motion pictures, and Karl S. J. Hohlen, Lincoln, president, state medical society, "Practical Points in Diagnosis and Treatment of Common Brain Conditions," illustrated.——Dr. Arnold C. Blattspieler, Tobias, was host to the Saline County Medical Society, October 30, at a dinner; the program included papers by Drs. John Thompson on "Treatment of Various Gastro-Intestinal Disorders"; Harry H. Everett, Lincoln, "Basic Anesthesia in Surgery, Especially in General Practice," and William O. Colburn, Lincoln, "Acute Anterior Poliomyelitis"; among other guests was Dr. Karl S. J. Hohlen, president of the state medical society.——The Dawson County Medical Society was addressed, October 4, at Cozad by *Dr. Adolph Sachs, Omaha, on diabetes.*

NEW YORK

Hospital Accounting System.—An important accomplishment of the United Hospital Fund during the year was the organization of the New York Conference on Hospital Accounting, in which nearly 100 hospitals in the city have cooperated. The system consists of the development of uniform arrangements of accounting, the standardization of statistics and records, the establishment of a more equitable basis of distribution of the money which the fund raises for its members, and the launching of a university course in hospital accounting.

Plan to Measure Efficiency of County Societies.—Dr. William H. Ross, Brentwood, president of the state medical society, at a meeting of the Third District Branch, September 9, at Albany, discussed the extent to which county societies were carrying out the policies of the state society. The following activities promoted by the state society were considered: reporting meetings in the journal; giving courses in graduate education; making public relations survey; county laboratories; county tuberculosis hospitals and county public health nurses. The two societies having the fewest members reported the greatest number of meetings during the past five years, while societies having the largest membership and the most regular meetings had not made a single report of their meetings to the journal. Dr. Ross plans to chart activities of the eight district societies for publication in the state journal. The scientific program of the third district meeting consisted of talks by Dr. Max M. Peet, Ann Arbor, Mich., on "Head Injuries," and Dr. Burton J. Lee, New York, "Surgery and Irradiation in the Treatment of Cancer."

New York City

Hospitals Aided by Convalescent Homes.—According to a statement of the Hospital Information and Service Bureau of the United Hospital Fund in *New York Medical Week*, increasing importance is attached to the work of sixty-eight convalescent homes serving New York City on account of abnormal demands on hospitals through the current period of unemployment and business depression. The bureau notes increasingly heavy demands for free accommodations in hospitals, so that their facilities and budgets are seriously taxed. To help meet this situation, the work of the convalescent institutions is being stimulated and coordinated. The bureau serves as a clearing house for information about hospitals and for the receipt of applications for service in convalescent institutions.

Society News.—The program of the October 27 meeting of the Medical Society of the County of New York consisted of talks on puerperal mortality and its possible reduction by Drs. George W. Kosmak; John O. Polak, Brooklyn, who described the routes of infection following birth injuries, and John Whitridge Williams, Baltimore, who presented a clinical consideration of the deaths from puerperal infection that occurred in Johns Hopkins Hospital during the past ten years.——Dr. Frank Billings, Chicago, gave the first of a series of afternoon lectures to the physicians of Harlem, October 23, in the Association of Trade and Commerce Building, on "The Need and the Outlook for the Continuing (Postgraduate) Education of the Negro Physician in America." This is a part of the program for graduate medical instruction sponsored by the North Harlem Medical Society.——The New York Roentgen Society and the New York Academy of Medicine were addressed at a joint meeting, October 20, by Dr. Coleman B. Rabin on "Pulmonary and Pleural Tumors—Correlation of Roentgenologic and Pathologic Findings"; demonstration of specimens and slides.——Dr. Foster Kennedy delivered the first of the series of afternoon lectures at the New York Academy of Medicine, November 7, on "Epilepsy and the Convulsive State"; the second lecture will be given by Dr. Frank H. Lahey, Boston, November 14, at 4:30, on "Carcinoma of the Colon," and November 21, by Dr. George Gray Ward, Jr., "Treatment of Pelvic Infections."

NORTH CAROLINA

Society News.—The Ninth District Medical Society was addressed at Salisbury, September 25, among others, by Drs. David S. Asbill, Statesville, on "Some Observations on Bronchoscopy," and Charles W. Armstrong, Salisbury, "Home Treatment of Tuberculous Children." Banquet speakers were Drs. James K. Hall, Richmond, Va., on "The Physician as Community Counselor"; John T. Burrus, High Point, "The Importance of Organized Medicine."——Among other speakers at the October 9 meeting of the Eighth District Medical Society at Greensboro, were Drs. Robert E. Smith, Mount Airy, "The General Practitioner's Aid to Nature in Obstetrics," and Marion Y. Keith, Greensboro, "Ramblings About Pellagra."

PENNSYLVANIA

Society News.—The principal address of the annual Mercy Day at Mercy Hospital, Pittsburgh, September 24, was delivered by Dr. Frank Norman Wilson, Ann Arbor, Mich., on "Cardiac Weakness and Cardiac Failure."——Dr. Robert A. Knox, Washington, addressed the Washington County Medical Society, October 15, on "Hypertrophic Stenosis of the Pylorus."

Personal.—Dr. Jacob P. Strayer, Oil City, was honored, September 26, at the meeting of the Venango County Medical Society on the completion of fifty years in the practice of medicine.——Dr. Henry E. Austin, Upper Darby, has been appointed by the District of Columbia commissioners chief resident psychiatrist at the Gallinger Hospital, Washington, which is a new position.

State Medical Election.—At the annual meeting of the Medical Society of the State of Pennsylvania, October 6, Dr. Ross V. Patterson, Philadelphia, was installed as president; Dr. William H. Mayer, Pittsburgh, was made president-elect, and Dr. Walter F. Donaldson, 8103 Jenkins Arcade, Pittsburgh, reelected secretary. The next annual session will be held at Scranton, Oct. 5-8, 1931.

Philadelphia

Dr. McKenzie Retires as Professor of Physical Education.—At the recent celebration of medical progress at the University of Pennsylvania, it was announced that Dr. Robert Tait McKenzie would retire as professor of physical education and physical therapeutics on the completion of a survey of student health. Dr. McKenzie will retain an affiliation with the university, his position to be announced later. He will devote most of his time to sculpture, in which work he is widely known. He was sculptor of the Franklin Statue at the university, the Scottish-American War Memorial at Edinburgh, and the War Memorial in the Parliament Building at Ottawa.

Dr. Tucker Becomes Professor of Bronchoscopy.—Beginning with the session of 1930-1931, Dr. Chevalier Jackson became emeritus professor of bronchoscopy and esophagoscopy in the Graduate School of Medicine of the University of Pennsylvania and consultant to the Graduate Hospital of the University of Pennsylvania. Dr. Jackson will continue his special courses of instruction in the Graduate School of Medicine. At the same time Dr. Gabriel Tucker, formerly associate professor, became professor of bronchoscopy and esophagoscopy in the Graduate School of Medicine and in charge of the Chevalier Jackson Bronchoscopic Clinic of the Graduate Hospital of the University of Pennsylvania. Dr. Jackson resigned from the University of Pennsylvania about a year ago to devote his time to the development of a bronchoscopic clinic at the Samaritan Hospital and to his professorship at Temple University School of Medicine.

Galen's Birth Commemorated.—The College of Physicians of Philadelphia held a meeting, October 23, to commemorate the anniversary of the birth of Galen, the greatest Greek physician after Hippocrates, and the founder of experimental physiology. Galen was the most voluminous of all ancient writers. After his death European medicine remained at a level for nearly fourteen centuries. Galen's work included nine books on anatomy; seventeen on physiology; six on pathology; sixteen on the pulse; the Megatechne, or therapeutics (fourteen books); the Microtechne, or practice, and thirty books on pharmacy. At the College of Physicians' commemoration, ninety-three copies of the ninety-eight Galen publications, the property of the college library, were on exhibition. The meeting was addressed by Drs. William H. Welch, Baltimore; Charles W. Burr, Philadelphia; Burton Chance, Philadelphia, and Giuseppe Franchini, Bologna, Italy.

TENNESSEE

Society News.—The Nashville Academy of Medicine was addressed, September 30, by Dr. Lucius E. Burch on "Uterine Bleeding." Dr. Rogers N. Herbert, Nashville, addressed the academy, October 21, on "Reflex Pain with Reference to Rectal Pathology."——Dr. James P. Taylor addressed the Bedford County Medical Society, September 18, on "Endocrine Disturbances."——"Duodenal Ulcer" was the subject of Dr. Estill E. Caudill, Elizabethton, before the Carter County Medical Society, September 2.——Dr. Charles E. Evans, Tullahoma, addressed the Coffee County Medical Society, October 13, on "Artificial Feeding of Babies."——The Davidson County Medical Society was addressed, September 23, by Dr. Jefferson C. Pennington, Nashville, on "The Significance of Urethral Discharge in the Male"; the society was addressed, October 14, by Dr. Barney Brooks, Nashville, on "Congenital Pyloric Stenosis."——Among others addressing the Knox County Medical Society, September 25, were Drs. Drew W. Luten, St. Louis, on "The Clinical Use of Digitalis," and William W. Potter, Knoxville, "The Eye as a Diagnostic Medium."——The Memphis and Shelby County Medical Society was addressed, September 2, among others, by Dr. Cecil D. Gaston, Birmingham, on "Etiology, Diagnosis and Management of Fistula in Ano."

UTAH

State Medical Election.—At the annual meeting of the Utah State Medical Association, September 10, Dr. William L. Rich, Salt Lake City, was installed as president; Dr. Richard A. Pearse, Brigham, was made president-elect, and Dr. Maurice M. Critchlow, Salt Lake City, reelected secretary. The next annual session will be held at Salt Lake City, Sept. 9-11, 1931.

VERMONT

State Medical Meeting and Election.—At the one hundred and seventeenth annual meeting of the Vermont State Medical Society in Burlington, October 2-3, Drs. Frank R. Ober, Boston, spoke on "Operative and Postoperative Treatment of Infantile Paralysis"; John F. Gile, Hanover, N. H., "Some Aspects of Pancreatic Surgery"; Mervin C. Myerson, New York, "Diagnosis and Treatment of Lung Conditions by Means of Bronchoscopy"; Clarence H. Beecher, Burlington, "Diagnosis and Treatment of the Cardiac Arrhythmias"; George H. Bigelow, Boston, "Can Communicable Disease Be Controlled?" and George R. Anderson, Brattleboro, "Hypertrophy of the Prostate from the Standpoint of the General Practitioner." A symposium on traumatic surgery was also conducted. Dr. William M. Johnstone, Morrisville, was elected president of the association for the ensuing year, and Dr. William G. Ricker, 31 Main Street, St. Johnsbury, reelected secretary. The next annual meeting will be in Rutland, in October.

WISCONSIN

Propose Compensation for Automobile Accidents.—An attempt will be made in the coming legislature to enact an automobile accident compensation law similar to the present industrial law. It has been shown that three times as many people are hurt in automobile accidents as in industrial accidents. The proposed law would provide that people killed or hurt in motor car accidents would get compensation regardless of the question of negligence. It is said that compulsory liability and insurance do not adequately meet the need for financial protection in auto accidents.

Society News.—The Third Councilor District Medical Society was addressed, October 17, among others, by Drs. James H. Mitchell, Chicago, on "Recent Advances in Diagnosis and Treatment of Malignancy of the Stomach," and Joseph L. Miller, Chicago, "Monilia Infection of Skin and Mucous Membranes."——Dr. Francis D. Murphy, Milwaukee, addressed the Winnebago County Medical Society, October 17, on cardiorenal disease with especial reference to hypertension.

—The Chippewa County Medical Society conducted a symposium on the diseases of the gallbladder, October 14; among the participants were Drs. Joseph Gale and Ray C. Blankinship, Madison.——"The Current Attitude Regarding Epilepsy, Its Nature and Rational Treatment" was the subject of Dr. Albert W. Bryan, Madison, before the Marinette-Florence County Medical Society, October 9.——Dr. William B. Castle, Boston, addressed the University of Wisconsin Medical Society, October 23, on "Relationship of Achylia Gastrica to Pernicious Anemia."

CANADA

Changes at University of Western Ontario.—The following changes, among others, have recently been announced at the University of Western Ontario Medical School, London.

Dr. Henry Alan Skinner to associate professor of anatomy.
Dr. Madge T. Macklin to assistant professor of histology and embryology.
Dr. Russell A. Waud to associate professor of pharmacology.
Dr. John H. Fisher to professor of bacteriology.
Dr. Albert J. Slack to associate professor of public health.
Dr. Frank R. Clegg to associate professor of obstetrics and gynecology.
Dr. William P. Tew to associate professor of obstetrics and gynecology.

Society News.—A special study is being made by the eye, ear, nose and throat section of the Winnipeg County Medical Society cooperating with the department of health and public welfare, for the reduction and possible eradication of trachoma in Manitoba.——The Vancouver Medical Association was addressed, October 7, by Dr. Maurice F. Dwyer, Seattle, on "Interpretation of Gastric Symptoms," a clinical and roentgenologic study of 3,000 cases; Drs. James G. McKay and Arthur L. Crease, Essondale, B. C., addressed the society, November 4, on "Early Recognition and Treatment of Psychoses"; the speakers, December 2, will be Drs. Edward H. Saunders and N. E. MacDougall, "Early Recognition of Acute Mastoiditis" and "Treatment of the Common Cold," respectively.

Physicians for Rural Districts.—The problem of medical care in sparsely settled areas in Saskatchewan is being solved by the operation of the rural municipal act passed about a year ago. This gives every municipality the right to make a grant up to $1,500 annually to a legally qualified medical practitioner who is a resident or is easily accessible on call, or it may guarantee his income to that figure. The municipal physician must give free medical service to indigents and perform the necessary duties of a health officer. On demand of twenty-five taxpayers, the council must submit a by-law to the electors empowering the council to engage a physician for full-time service at a salary not exceeding $5,000 a year. Of Saskatchewan's 866,700 people scattered over 251,700 square miles, 14.4 per cent live in the eight cities; 7.7 per cent in the eighty towns; 2.9 per cent in unorganized territory, and 1.3 per cent are Indians on their reservations. This gives an extensive area needing medical service which now has little appeal to young physicians seeking to earn an immediate livelihood. Under this cooperative health measure, it is reported, there are thirteen rural municipalities paying medical grants of from $900 to $1,500 annually. Nineteen other municipalities have engaged municipal physicians at salaries varying from $3,500 to $5,000 a year. The system guarantees a reasonable income to the physician and gives the settlers a needed medical service.

Department of Public Welfare Created.—On recommendation of the Royal Commission on Public Welfare in Ontario, Premier Ferguson has announced the creation of a department of public welfare with Hon. W. G. Martin as minister. The commission advises that public funds finance the general hospitals, which now receive for indigent patients a grant of 60 cents daily per patient from the province, and $1.75 daily per patient from the municipality. The total general hospital revenue last year was $10,140,782. The commission emphasized the need of a government owned psychiatric hospital and to assist institutional schools in caring for Ontario's 6,000 crippled children, 2,000 blind and 3,000 deaf and dumb persons, recommended the division of the province into ten districts, in each of which will be stationed a graduate nurse or social worker supervised by a special government officer. It was recommended that the raising of funds to effect other recommendations of the commission should be patterned after the Quebec plan, in which more than $600,000 is raised annually by a hospital tax of 5 per cent of the cost of all meals over $1, levied in hotels and restaurants. Among the recommendations was one which advised that a special conference of medical men be convened to study cancer treatment and that the province establish a cancer hospital and purchase a supply of radium. Emphasis was laid on the need of preventive clinics, provisions for occupational training for convalescents, and aid in the rehabilitation of tuberculous patients on discharge.

GENERAL

Guides for Graduate Study.—The New York Academy of Medicine has published booklets to aid visiting medical men. "The Synopsis of Approved Opportunities for Postgraduate Medical Study in the Clinical Specialties" lists courses and residencies. "Opportunities for Postgraduate Medical Study Offered in New York City" has been revised to include a map showing important hospitals, facilities which the academy offers to visiting medical men, approved courses and residencies, fellowships, nonoperative clinics and conferences, clinical and pathologic conferences and ward rounds. Copies of the foregoing may be obtained from the New York Academy of Medicine, Fifth Avenue and One Hundred and Third Street, New York.

Posing as Physician's Son.—On July 28 a well dressed young man called at the office of Dr. William Gerry Morgan, Washington, D. C., and introduced himself as Charles Albert Perkins, Jr., the son of a classmate and close friend of Dr. Morgan. He stated that he had met with an automobile accident in Maryland, had been arrested and fined, and was in need of money to get him back to the Cleveland Clinic, where he was an intern. Dr. Morgan lent him $50, which he promised to return soon. Not having heard from him, Dr. Morgan recently wrote to the Cleveland Clinic asking if such a young man was attached to their staff. The reply came that there was no such young man there nor had there ever been one of that name.

Dr. Landsteiner Wins Nobel Prize.—Dr. Karl Landsteiner, bacteriologist and pathologist on the staff of the Rockefeller Institute for Medical Research, New York, has been awarded the Nobel Prize for Medicine. Dr. Landsteiner was born in Vienna, graduated at the University of Vienna in 1891, and was pathologist there from 1909 to 1919. He has been a member of the Rockefeller Institute for Medical Research since 1922. The prize amounts to about $48,000. The award was based on Dr. Landsteiner's research in connection with blood groups. He is known also for his research on infantile paralysis, paroxysmal hemoglobinuria, and blood serum in relation to immunity. The only other American to have received the Nobel Prize for Medicine was Dr. Alexis Carrel, to whom it was awarded in 1912.

New Veterans' Hospitals.—Sites for several of the nine new veterans' hospitals involved in the veterans' bureau construction program have been chosen. The hospital for Alabama will be located near Tuscaloosa; it is to contain 250 beds, will be erected at a cost of $1,100,000, and will include accommodations for a regional office. The hospital for western New York, to be located near Canandaigua, will have 400 beds and will be built at a cost of $1,700,000. The West Virginia hospital, with a 125 bed capacity and to cost $700,000, will be located near Huntington. The New Mexico Hospital will be a general hospital with 250 beds to cost $1,250,000 and will be located near Albuquerque. Facilities for the regional office and 200 beds for general medical and surgical patients will be provided for in the new hospital to be erected at a cost of $1,000,000 in New York City.

Society News.—At the annual election of officers of the American Protestant Hospital Association, October 20, in New Orleans, Dr. Benjamin A. Wilkes, Los Angeles, was installed as president.——Dr. Argus D. Willmoth, Louisville, Ky., was elected president of the American Physical Therapy Association at its annual meeting, October 9, and Dr. Cadwallader C. Vinton, 1650 Broadway, New York, reelected secretary.——Dr. John E. Jennings, St. Louis, was elected president of the Frisco System Medical Association at its annual meeting in Springfield, Mo., October 10-11, and Dr. Robert Vinyard, St. Louis, reelected secretary.——The first Mexican Congress on the Prevention of Blindness was held in Mexico City, November 1-6, under the auspices of the departments of public education and public health and of the National University of Mexico City. Papers were read on leprosy, cancer, tuberculosis, alcoholism, syphilis and the venereal diseases. The president of the congress was Dr. Daniel M. Velez.

LATIN AMERICA

Cancer Award Announced.—It was announced recently that the Uruguayan Association Against Cancer had voted an annual prize of 1,500 pesos for the best scientific study on human cancer, the award being made on the recommendation of a jury of six specialists appointed by the association. To be considered, a work must be entirely original, representing an experimental study on the etiology, pathogeny, early diagnosis or treatment of the disease, and possess positive value as a contribution to knowledge on the subject. Any Uruguayan is eligible to compete for the award.

FOREIGN

Prize for Method of Detecting Mustard Gas.—The International Red Cross Committee at Geneva has announced that the international competition for the discovery of a reagent for the detection of mustard gas in the air, which was started July 1, 1929, is to close December 31. The prize offered is 10,000 Swiss francs (£400). Information concerning the competition may be obtained from the International Red Cross Committee, 1, Promenade du Pin, Geneva.

Investigation of Standardization of Drugs.—The governor general of India has appointed a committee to inquire into the extent to which drugs and chemicals of impure quality or defective strength are imported, sold or manufactured. The committee is to recommend legislative measures that would restrict the profession of pharmacy to duly qualified persons. It will visit important centers in the provinces to get evidence concerning drug standardization. The secretary is Lieut. Col. R. N. Chopra, I. M. S., School of Tropical Medicine and Hygiene, Calcutta.

Opening of Lockyer Collection.—The annual prize distribution and inaugural address at Charing Cross Hospital Medical School, October 4, was preceded by the opening of the Lockyer collection of obstetric and gynecologic specimens in the museum. The collection numbers nearly 2,000 specimens and is suitably housed in a large hall; it is the gift of Dr. Cuthbert Lockyer, consulting obstetric physician to the hospital. The gift, made in the centenary year of the school, is considered one of the most important collections that have been brought together by one person since the days of John Hunter, whose collection was said to be the basis of that of the Royal College of Surgeons.

Insurance Medical Service in England.—The extent and cost of insurance medical service in England for 1929 recently reported by the minister of health showed that 14,600 physicians were engaged in insurance practice. The number of insured persons entitled to medical benefit was a little over 14,000,000. The cost of their service was £8,666,000. Medicines and appliances were supplied as a part of medical benefit by about 9,000 chemists' shops. Of the total cost of medical benefit £6,256,000 were given to panel physicians and £1,922,800 was paid to panel chemists for the supply of drugs and appliances. About £200,000 was paid to country practitioners for mileage, that is, in practices in which the physical conditions were such that distances covered were not in themselves a fair measure of the physicians' difficulties. Nearly £10,000 was set aside to enable country practitioners to attend courses of graduate study and to provide them with facilities of telephones, motor cars and branch surgeries; £194,800 was allotted to physicians for medicines and appliances used in emergency treatment for their medicines dispensed in districts where patients were out of reach of chemists.

Rural Health Experiment in China.—Ting Hsien is a typical Chinese county selected for the health program to be financed by the recent donation of $50,000 by the Milbank Memorial Fund. The announcement follows closely on the news from Geneva that the League of Nations will support and cooperate in attempts to modernize China's health service despite that country's seeming preoccupation with civil war, her chaotic political situation and seriously disturbed industrial condition. The experiment is part of the Chinese National Association of the Mass Education Movement. It is of pioneer importance in applying modern scientific knowledge to a population which has an annual death rate of approximately 30 per thousand at an average expectancy of life at birth of only thirty-five years. Ting Hsien has one city of 80,000 population; sanitation is unknown and conditions of living are almost unbelievably primitive. Over 90 per cent of the people are illiterate. The mass of the population live in villages in mud huts. In the whole county of 400,000 people there is not a qualified modern trained physician.

Deaths in Other Countries

Prof. Henri Delagenière, LeMans, France, suddenly on September 30, in Royan, France; he had been known for work on osteoperiosteal grafts.——**Major General Sir Neville Howse**, minister of health and repatriation of the Australian commonwealth since 1925, in London, September 19, aged 67.

Government Services

Army Personals

Major Samuel E. Brown to duty at Mather Field, Calif.; Major Guy D. Griggs to duty at Kelly Field, Texas; Major Thomas L. Gore, in addition to his other duties is assigned as flight surgeon; Lieut. Ralph Vernon Plew to duty at the Walter Reed General Hospital, Washington, D. C.; Major John W. Watts will sail from New York for the Philippine Department about January 13; on arrival at Manila, he will report to the commanding general for assignment to duty with the medical corps; Lieut. Edward James Kendricks, to duty at Fort Leavenworth, Kan.; Major Robert B. Shackelford, Fort George G. Meade, Md., will proceed to his home and await retirement for the convenience of the government; Capt. John P. Russell, relieved at the Panama Canal, Canal Zone, and on completion of present tour of foreign service is assigned to Mather Field, California; Major James E. Ash will sail from New York about February 17 for San Francisco for duty in the Letterman General Hospital; Major Virgil H. Cornell relieved at San Francisco and assigned to duty at Army Medical School, Washington, D. C.

Surgeon General Ireland Reappointed

President Hoover has approved a recommendation of Secretary of War Hurley that Major Gen. Merritte W. Ireland be reappointed surgeon general of the army, effective October 30. This is the fourth appointment of Major General Ireland as surgeon general. In determining to permit him to finish his active army service in his present office, the President made an exception to the general rule against reappointments for the heads of branches and bureaus. General Ireland will reach the retiring age, May 31. He was first appointed surgeon general of the army, Oct. 30, 1918. He had previously served as chief surgeon of the American Expeditionary Forces and also as surgeon general. He was reappointed surgeon general, Oct. 30, 1922, and again, Oct. 30, 1926.

U. S. Public Health Service

Surg. William H. Slaughter, relieved at marine hospital, Cleveland, about October 10, and assigned to duty at Memphis, Tenn., in charge of the marine hospital at that place; Surg. R. L. Allen, relieved at Memphis and assigned to duty at marine hospital, Fort Stanton, New Mexico, in charge of the hospital; Acting Asst. Surg. J. E. Smith, relieved from duty at Knoxville, and assigned to duty at trachoma hospital, Rolla, Mo.; Surg. Herbert A. Spencer, directed to assume charge of the work at the immigration station on Angel Island, Calif., in addition to duties as medical officer in charge of the U. S. Quarantine Station at Angel Island; Medical Director Dana E. Robinson, assigned to duty in the office of the American Consul General, Quebec, Canada; Asst. Surg. Fred W. Kratz, assigned to duty at the U. S. Marine Hospital, Stapleton, N. Y.; P. A. Surg. Alfred J. Aselmeyer, assigned to duty at the Federal Penitentiary Annex, Fort Leavenworth, Kan.; P. A. Surg. William H. Gordon, assigned to duty at marine hospital, Key West, Fla.; Senior Surg. Friench Simpson, relieved at Oslo, Norway, and assigned to duty at Dublin, Irish Free State; Senior Surg. Randolph M. Grimm, relieved at Dublin, Irish Free State, and assigned to duty at Ellis Island, N. Y.; the following physicians were promoted and commissioned as passed assistant surgeons in the regular corps of the service: Hiram J. Bush, Houston G. Foster, Samuel J. Hall, Edgar W. Norris, Jr., Donald P. Ross and Aubrey E. Snowe.

The Government Needs Physicians

The U. S. Civil Service Commission states that government hospitals throughout the country, including those under the veterans' bureau, the public health service, Indian service, and other branches, are in need of medical officers and nurses of various grades, and that veterans' bureau hospitals have vacancies in positions of psychiatric social worker and junior social worker. Full information regarding examinations, salaries, and so forth, may be obtained from the U. S. Civil Service Commission, Washington, D. C., or from the secretary of the U. S. Civil Service Board of Examiners at the postoffice or customhouse in any city.

Report of Radium Commission

The appointment by the government of the radium trust and the radium commission has already been described (The Journal, Nov. 16, 1929, p. 1572, and Dec. 14, 1929, p. 1899). The radium treatment of malignant disease was considered so important that a fund of $1,500,000 was formed by public subscription and the contribution of $500,000 by the government. The body of national trustees which buys radium and controls its custody is the radium trust. Its work is directed by the radium commission, which makes arrangements for the equitable distribution and full use of this radium, both for treatment and for research. The trust and the commission have now issued their first annual report. March 31, the trust had 9,215 Gm. of radium, which cost $473,000. An agreement was made with the Union Minière du Haut Katanga for the purchase of radium at $50 a milligram, which is considerably below the current market price, in consideration of the fact that the trust was purchasing for a central national stock. The union also placed at the disposal of the trust a bomb of 4 Gm. on loan free of charge for three months with option of purchase. This bomb was purchased in February for $207,000. In March the commission recommended the acquiring of a supply of radium for the preparation of radon, for which 3 Gm. was bought. In the use of radium the commission has carried out a policy of concentration, restricting the distribution to places possessing a university with a medical school. Only one hospital—nominated by the medical faculty of the local university and approved by the commission—is recognized as the national radium center for the area concerned. Only in this way was it thought practicable to retain effective control over distribution and use, and experience has so far justified the decision.

SCHOOL OF RADIOTHERAPY

The commission considers that the need for a large number of physicians fully qualified to practice radiotherapy is at least as urgent as an increased stock of radium, and it has been much impressed by the lack of adequate facilities for the teaching of this all-important subject. One of its first preoccupations has therefore been the creation of a national postgraduate school of radiotherapy in London. It was evident that the scale, equipment and operation of an adequate center was beyond the resources of any existing teaching hospital, while, on the other hand, it was felt undesirable that the new school should have to wait for the projected empire postgraduate medical college or become absorbed in it. The commission came to the conclusion that the best solution would be the cooperation and, if practicable, the amalgamation of two existing institutions—the Mount Vernon Hospital at Northwood, Middlesex, and the Radium Institute in London. An arrangement has been made whereby the main clinical and pathologic work of the joint institution will be carried out at Mount Vernon, while the diagnostic and outpatient department, with a proportion of the surface therapy work, will be centered at the Radium Institute, which will also be the principle center for the supply of radon. The total amount of radium allocated to the joint center will be: Mount Vernon Hospital, 3 Gm. for clinical work; Radium Institute, 1 Gm. for radon. This will be in addition to the existing supplies of the two institutions. The postgraduate school has been inaugurated and a comprehensive course of instruction has been approved.

THE POSTPONED VERDICT ON RADIUM TREATMENT

The conclusion reached by the commission is that great caution is necessary in estimating the value of radium in the treatment of malignant disease and it deprecates the creation of false hopes by sensational and even optimistic statements. As a result of world experience extending over many years, the best that can be said is that some results under certain conditions are satisfactory while others, for no clearly established reasons, are less so, and that in a considerable proportion of cases the results are inconclusive or disappointing. But this does not justify a pessimistic outlook, as many problems yet unsolved may yield to experience and research. But time is an essential condition of success and only after several years of pioneer work can there be sufficient data for positive conclusions. The commission has therefore made its first duty to organize a concentrated and controlled national radium service, of which the progress and results will be recorded after a uniform system. Finally, the commission feels bound to repeat its warning that radium is not yet established as a "cure for cancer"; that while it holds out good promise of beneficial results, and certainly of alleviation of suffering, it is at present a dangerous weapon and one which, unless used with the greatest skill, care and caution, may easily be productive of more harm than good. This is the considered opinion of the commission as the result of its first year's work; but at least five years' further experience and coordinated research will probably be required before any final verdict can be anticipated.

A Survey of Population: Continued Decline of the Birth Rate

The registrar-general's statistical review for 1929, just published, shows that the estimated population of Great Britain and Ireland was 48,684,000, compared with 48,574,000 in 1928, an increase of 110,000, or 0.23 per cent. Taking the constituent parts of the British Isles separately, there was an increase in England and Wales and a decrease in Scotland and the Irish Free State. The estimated population of England and Wales in 1929 was 39,607,000, against 39,482,000 in 1928, an increase of 125,000, or 0.32 per cent. For Scotland the figures are 4,884,000 and 4,893,000, a decrease of 9,000, or 0.18 per cent; for the Irish Free State 2,943,000 and 2,949,000, a decrease of 6,000, or 0.2 per cent. The marriage rate for England and Wales during 1928 was 15.8 per thousand living and was the highest since 1921. The number of divorces was 3,396 against 4,018 in 1928, a decrease of 15.5 per cent. The birth rate was 16.3 per thousand of population, against 16.7 in 1928, thus continuing the steady fall of recent years. The proportion of male to female births was 1,043 to 1,000, a close approximation to that in recent and prewar years. The maximum was 1,060 to 1,000 in 1919.

Spahlinger Again

In The Journal, Dec. 15, 1928, page 1904, the concerted attempts in the press to boost Spahlinger's secret "cure" for human tuberculosis were described. The exposure of his pretensions by one newspaper, the *Daily Express*, seems to have stopped this. The paper sent a special correspondent to Geneva, who found that while a large income was being derived from patients at the Spahlinger Institute there were many failures, of which nothing was said in the roaring propaganda. Moreover, the *Express* offered to pay $50,000 toward Spahlinger's work on condition that he would allow a committee of experts to examine and report on it; but he refused. Then Spahlinger turned his attention to animals and promoted a company in this country for their treatment by means of his vaccines. Note that it is always in England, never in his native Switzerland, that Spahlinger tries to exploit his vaccines. He has bobbed up again in this country. This time he does not seem to have received any backing from the ordinary press, but the organ of the labor party, the *Daily Herald*, has a column devoted to his methods and adorned with his portrait and a microscope "in his laboratory." Under captions such as "Safe Milk" and

"Anti-Infection Hope for Babies," we are told that "experiments are being carried out with cattle on a Norfolk farm under a veil of secrecy. In about three months the experiments will be completed. Then it is likely that M. Spahlinger will issue a full report."

ITALY

(From Our Regular Correspondent)

Sept. 30, 1930.

International Congress on Malaria

The Second International Congress on Malaria was held in Algeria. Representatives from thirty-eight countries attended, and Professor Lutrario, president of the Commissione malariologica della Società delle Nazioni, was the head of the Italian delegation.

Before the section on parasitology, Dr. G. Raffaele of Rome spoke on the classification of the plasmodia found in birds. Owing to the impossibility of transmitting human malaria to animals, and by reason of the resemblance between malaria parasites of birds and those of man, research carried out with birds may be applied to man. The speaker was able to distinguish, in Italy, two types of plasmodia in birds—namely, *Plasmodium praecox* of Grassi and Feletti and *Plasmodium majus,* which was differentiated by Raffaele himself. Usually the two species are associated.

Before the section on entomology, Professor Franchini of Bologna presented a paper on the anopheline fauna of the Italian colonies.

Addressing the section on epidemiology, Drs. Missiroli and Hackett of Rome mentioned the spontaneous disappearance of malaria in zones surrounded by malarial territory and infested, at the time, with *Anopheles maculipennis.* The speakers, who have done research in various malarial localities, deny that the widespread use of quinine has suppressed the carriers of gametocytes. It seems plausible to assume that there has been a diminution in the relations between anopheles and man as a result of the increase in the number of stabled animals. Animals have an attraction for anopheles and thus they are diverted from man. It may be noted also that zoophilism in anopheles develops slowly, over a period of years.

In the section on clinical pathology, Mazzolani of Tripoli spoke on the relations between tuberculosis and malaria, and expressed the view that the relations vary with the stage of the tuberculosis and with the nature of the malarial infection. Sometimes a complete antagonism may exist between the two diseases.

Addressing the section on prophylaxis, Dr. Jandolo explained the new trends of Italian legislation in regard to health movements. Professor Lutrario spoke of the work of the commission on malaria of the League of Nations, which has made investigations and epidemiologic research in various countries, and has promoted the training of technical personnel in the schools of Hamburg, London, Paris and Rome. The speaker pointed out that Italy had shown great activity in the malaria crusade through (1) increasing the supply of the specific remedy by the governmental administration of quinine and the creation of plantations of Cinchona in Java and in Eritrea, (2) the training of technical personnel, and (3) the redemption of malarial regions by drainage.

The Death of Professor Fano

The death of Prof. Giulio Fano, senator, director of the Istituto di Fisiologia Generale of the University of Rome, at Mantua, his native city, September 27, after a brief illness, is announced. Born in 1856, he graduated at Turin at an early age and soon thereafter took up the study of physiology. When scarcely 28 years old, he was called to the chair of physiology at the University of Genoa. In 1894 he succeeded Luciani at the University of Florence, and in 1917 he became director of the Istituto di fisiologia generale at the University of Rome, which post he held up to the time of his death. He was the author of many works through which his name was known throughout the world. Among his chief works are those on coagulation of the blood and the behavior of peptonized blood and lymph; also on the inhibitory brain centers. His studies on the thyroid class him among the pioneers in endocrinology. The work entitled "Brain and Heart," which has been translated into French and English, gives a series of lectures that Professor Fano held at the University of Barcelona, and contains an exposition of his principal discoveries in the field of physiology. He was founder of the journal *L'Archivio di fisiologia,* was a member of the Accademia dei lincei and of many other learned societies, and had received the title of "senator" (1911). Among his pupils may be mentioned Professors Bottazzi, Herlitzka, Ducceschi, Rossi and Spadolini, who occupy chairs of physiology in the universities of Naples, Turin, Padua, Florence and Siena.

The Records of Medical Aid to Children

The ministry of the interior has issued instructions that all institutions furnishing aid and sanitary prevention for the young shall cooperate in the defense against social diseases, especially tuberculosis. Aid shall be given not only to the larger communities but also to the rural districts. The point of departure of such activity shall be the medical examination of the children at an early date and repeated from time to time. For each child examined a record-book shall be made out, which must be kept up to date, with an account of diagnoses and forms of treatment and the results. Also statements in regard to accidents suffered must be recorded. In addition, for each child a so-called biotypologic record-card will be made out, the chief purpose of which is to follow the child through the various cycles of his development. A number of "official physicians" will be appointed to provide medical aid for the young.

Visit of American Physicians

About one hundred American physicians, members of the Postgraduate Medical Association of North America, visited recently the principal clinics of Rome and Florence. Some were general practitioners, some were surgeons and some were specialists. They attended lectures in Rome on surgery and urology, internal medicine, neuropathology and psychiatry, and the like, and participated in operative sessions in various clinics. They visited also the Mussolini institute for the prevention and treatment of tuberculosis and attended lectures and operations in thoracoplasty. From Rome they proceeded to Florence to visit the clinics at the university.

Compulsory Insurance for Health Officers

According to a recent law, the obligation of being insured in the Cassa di previdenza was extended (as of Jan. 1, 1930) to all health officers of the provinces and the communes. These physicians and their dependents are thus entitled to receive social and financial aid. Orphans of health officers are entitled to aid and to instruction in the Istituto per gli orfani dei sanitari, located in Perugia.

Latin as the Language of Medical Science

Prof. Cesare Orsali of Rome is carrying on a campaign in the medical press in favor of the adoption of the Latin language as the official idiom of medical science in all civilized countries. Professor Orsali has suggested that, in order to bring about a realization of this idea, an international medical congress be organized at which Latin shall be the sole official language, and that a medical journal employing only the Latin language be published, to which the scientists of all countries would be invited to contribute articles.

The Address of Dr. Rosenow

Through the initiative of the Federazione stomatologica italiana, Dr. Edward C. Rosenow of Rochester, Minn., delivered in the amphitheater of the Clinica odontoiatrica in Rome an address on "Clinical and Experimental Studies on the Selective Localization of Streptococci." Dr. Rosenow illustrated, with *numerous lantern slides, the* results of fifteen years of experimental work directed toward the reproduction in laboratory animals of disease of various organs, developing in consequence of intravenous injections of cultures of streptococci derived from foci of infection originating chiefly from devitalized human teeth. From these teeth, extracted from persons who were suffering from a distant focal infection and who were cured as a result of the extraction, cultures of streptococci were obtained. When injected into animals, these develop the same disease from which the patient suffered, as a result of the localization of microorganisms in the corresponding organs. These results throw light on the pathogenesis of certain obscure conditions and show the responsibility of the dentist, whose work, if not conducted with the proper asepsis, may provoke in the teeth conditions that are reflected in other organs, thus compromising the health of the patient.

Examinations for the Doctorate in Medicine

The faculty of medicine of the University of Milan has submitted to the ministry of public education a number of proposals pertaining to the practice of medicine and surgery. According to the present regulations, the university statutes may establish the number of subjects in which examinations must be taken by the student who is a candidate for the degree of doctor of medicine, but the plan of study is only advisory and cannot be flatly imposed on the student. The student has the privilege of selecting, from designated subjects, those that he considers best adapted for his individual purpose.

The faculty of medicine of Milan holds that this conception is not entirely applicable to medical studies, which are calculated to make professional men of the majority of medical graduates —men and women who are useful not only to themselves but also to society.

Since it will doubtless be some time before medical studies are reorganized, as they will probably be eventually, the faculty of medicine of Milan has suggested that special scholarly requirements be set up for those who, already in possession of a degree in medicine, wish to take the so-called state examination, which is required for the practice of the sanitary art.

BELGIUM

(From Our Regular Correspondent)

Oct. 7, 1930.

International Assembly of Army Medical Services

The Belgian government held at Liége, July 18-21, an assembly of the heads of the land, sea and air departments of the army medical corps of the world for the discussion of the two questions: (1) creation of an international bureau of bibliography pertaining to military medicine, and (2) advantages to be derived from an exchange of military physicians in peace times. The assembly passed the following resolution, which has been forwarded to the governments of all countries: 1. It is proposed that there shall be organized, under the control of the permanent committee of the international congresses of military medicine and pharmacy functioning in Belgium, an international bureau of medicomilitary bibliography pertaining to the land, sea and air forces, which shall be at the disposal of all official services, in accordance with regulations to be established by the permanent committee, in accord with the nations accepting this agreement; that these nations shall aid the functioning of the bureau by supplying it as generously as possible with the relative documents they possess, and, in particular, that they shall contribute toward the administrative expenses on the basis of the classification of nations adopted by the League of Nations. 2. It is further proposed that the nations accept and favor the international exchange of officers of the medical corps of the various land, sea and air forces. This exchange should be effected by means of short courses of instruction or by the sending of lecturers to foreign countries, *in accordance with the forms decided* on by each country that endorses the project. The international bureau of medicomilitary bibliography will be found of aid, in this connection, as a bureau of information.

The proposals are now being considered by the various nations, and the permanent committee of the international congresses of military medicine and pharmacy, which meets at The Hague on the occasion of the sixth congress, in June, 1931, will be called on to approve and to complete the organization and to adopt the mode of functioning of the medicomilitary bibliographic bureau.

Bacteria on Paper Money

Mr. Girard has an article in the *Bruxelles Médical* on the bacterial contamination of paper currency. From numerous researches, he found that, per square centimeter of paper currency, *2,000 germs develop on a gelose medium and 3,000 germs* on a gelatin medium. Most of the bacteria obtained by culture are saprophytes: *Micrococcus prodigiosus, B. subtilis,* and germs belonging to the three groups *Megatherium, Mesentericus* and *Proteus;* but there are also pathogenic bacteria originating from the skin, saliva or intestinal tract of those who have handled the currency: *Staphylococcus pyogenes,* var. *aureus, albus* and *citreus, Micrococcus tetragenus, Leptothrix buccalis* and *Leptothrix asteroides* and *Bacterium coli commune.* Also spores of *Aspergillus, Penicillium, Mucor* and *Gladosporium* were encountered. Girard found no evidence of the bacilli of diphtheria or tuberculosis, or of pneumococcus, which require precise conditions for development. He studied the persistence on paper currency of germs deposited for experimental purposes. He gives, as the duration of survival, five days for the Koch bacillus, seven days for *Bacterium typhosum,* twenty days for the colon bacillus, forty-five days for the staphylococcus, and sixty days for the spores of anthrax.

Fourth Congress of Otoneuro-Ophthalmologic Societies

The fourth Congress of Otoneuro-Ophthalmologic Societies was held recently in Brussels, under the chairmanship of Prof. H. Coppez. Professor Brachet expressed in his inaugural address his pleasure over the federation of specialists. Terracol, Euziere and Pages presented a neurolaryngologic study on laryngeal paralyses. The diagnostic value of the laryngeal paralyses varies according as they exist in an approximately pure state or in association with more or less complex neurologic symptoms. Important characteristics point to the peripheral origin of a laryngoplegia: strict homolaterality, frequency of laryngeal anesthesia, muscular atrophy with disorders affecting *reactions to electrical stimulations, association* with the laryngoplegia of disorders pointing to nerve lesions or to multiple foci. To a bulbar seat of the causal lesion point more particularly: the apoplectiform onset, the motor disorders of the limbs of pyramidal or cerebellar nature, and the association of particular symptoms such as rotatory nystagmus, tachycardia and glycosuria. Suspicions of a radicular seat are awakened by the presence of laryngeal paralyses associated with symptoms pointing to involvement of multiple cranial nerves (outside of the nerves of bulbar origin). A trunk lesion may be considered in the presence of a laryngeal paralysis of slow development that evolves without the addition of other symptoms.

The laryngoplegias have likewise value for the determination of the etiology. In the disorders with a bulbar localization, the various diagnoses to be considered are essentially those of syndromes in a focus of vascular origin (preponderant rôle of syphilis), of syringobulbia, of chronic bulbar paralysis, of lateral amyotrophic sclerosis, of multiple sclerosis, of tumors, of acute anterior poliomyelitis, of epidemic encephalitis. Furthermore, the laryngeal paralyses have likewise considerable prognostic interest. From the neurolaryngologic point of view, it is evident that the laryngoplegias of bulbar origin are the most important. Their appearance during a neurologic disorder requires reserved statements as to the future of the patient. In a general way, every laryngeal paralysis awakens suspicion of a lesion of bulbar areas whose functioning is indispensable for the existence of the subject (respiratory or cardiac center). Every subject with a neurologic disorder, in whom bulbar involvement is to be feared, should be subjected systematically to a laryngoscopic examination. The truth is, a laryngoplegia may remain clinically latent, and many surprises might be avoided if the neurologist would take advantage of the regular collaboration of the laryngologist. Inversely, disorders of the voice, if they do not prove to be an expression of a laryngeal paralysis, could be given a more favorable prognosis.

CAPE TOWN

(From Our Regular Correspondent)

Sept. 19, 1930.

Vital Statistics

The bureau of census and vital statistics annually issues reports, which are usually condensed in the year book of the Union, the official government summary of what has happened during the past year. For many years the profession has felt that the basis on which the vital statistics of the Union are tabulated is wrong. That basis makes a distinction between European and native and between colored and native, with the obvious result that the percentages given are not correct. The latest figures of the Union give the European population as 1,738,937, as compared with 1,280,381 in 1911. The coastal areas are slightly more densely populated than the inland areas. The European birth rate is 25.8 per thousand of population, having dropped from 32.5 in 1910, and is lowest in the urban center, which is in some ways the least South African and receives the highest influx of new blood. The European birth rate is high when one compares it with that of Canada or England and Wales, and the rate of natural increase, the excess of births over deaths, is three times as great as that of England and Wales. In 1928 it was 15.6 per thousand of population. The European death rate is 10.15 per thousand and is 5 per cent higher than the average for the previous five years, an increase thought to be due to the increase in the number of persons in the higher age groups. The infant mortality rate was 70.5 per thousand European births, and appears to be stationary, but is 22 per cent below the average rate for the five years 1910-1914. The puerperal mortality rate is 5 per thousand European births, which is almost as high as that for England and Wales, and corresponds with that for Canada (5.5) and Germany (5.2). These figures give a thoroughly false conception of the real vital statistics of the Union. The larger part of the population is composed of aboriginal natives, while there is a section, growing in numbers and importance, of half castes, locally known as Cape coloreds. The death, infantile and puerperal mortality rates among these two classes are much higher than the figures here given, and probably much higher than the calculated figures sometimes quoted. But no one seems to mind. The central government has gone on dealing with public health matters as if these concerned merely the European part of the population. As a matter of fact the European population is so small, and in the urban areas it is so well looked after by thoroughly competent medical officers, that the central health administration might with advantage concentrate on the native and colored population. The published statistics are so inadequate that few realize how widespread is disease and deterioration among the white as well as among the native population. For political reasons this is denied, and politically everything possible is being done to confirm the South African in his belief that he can continue to be the predominant partner even without importing new blood and new strains into the Nordic population.

Medical Inspection of Schools

This tendency to underrate the importance of native health is well seen in the report of the medical inspectors of schools for the Cape Province. Although thousands of native children attend schools in the province, the medical inspectors confine their inspections almost wholly to European children. They report that 36 per cent of European children are defective but state emphatically that the defectiveness among such children is not higher in the province than elsewhere among civilized communities. Their figures have been challenged by former medical inspectors of schools, now in consultant practice, who point out that the figure of 18 per cent dental defectiveness is ludicrous, and that former inspections in the Cape Province gave a much higher general average of defectiveness. The real reason for this low figure is not that physical defectiveness is less prevalent in the Cape Province than it is in the Transvaal or in Natal but because in the Cape alone the medical inspectors follow the antiquated method of examining age groups only, instead of examining all the children, and devoting special attention to entrants and leavers. It is among the leaver group that the defects which militate most strongly against the economic usefulness of the child are found. Taking the Union as a whole, one may say that the prevailing defects found in leavers are remediable defects due to underfeeding or infection. Antenatal underfeeding and antenatal infection are responsible for much of the endocrine and pluriglandular insufficiency. Juvenile underfeeding and infection accounts for approximately one third of the defects discovered in leavers. While in the north malaria, bilharzia and malta fever and, perhaps, ciliate, flagellate and amebic infections produce much defectiveness, the main causes of defectiveness in the Cape Province are probably the same as those in Europe. Rheumatic fever and rickets do not, however, occur in the same relative proportion as they do in Europe or America. Rickets is more rare and occurs chiefly among the colored half castes. Rheumatic fever is probably the most prevalent juvenile disease, and its manifestations are sometimes so common as to raise the suspicion that there is a mild epidemic. Chorea and heart disease, resulting from rheumatic fever, are common enough.

Postinstitutional Care

Only recently has the public discovered that in many of these cases of juvenile defectiveness prolonged postinstitutional care is necessary. Our hospitals make no provision for such intensive convalescent treatment. So far only one proper "school of recovery" has been established. This is at Isipingo in Natal, and is mainly designed to receive children suffering from chronic malaria, who remain in the home for six months or longer and receive, while there, class instruction and clinical treatment. The home is able to deal with a few hundred children a year, but obviously the number of chronic malaria children needing institutional treatment is much greater than can be accommodated by one such school. Lately the Transvaal education department has established temporary treatment camps for the clinical treatment of bilharziatic children. The success obtained in these camps is striking, and the publicity given to them has stimulated the public to clamor for something similar for orthopedic and heart cases. A movement has now been set on foot to establish the Princess Alice School of Recovery at the Cape. Unfortunately the organizers have selected a spot some distance away from the sea, and it is possible that the difficulties of dealing with a site that permits of no adequate drainage and needs the installation of a septic tank will wreck the scheme. At present there is one cripple home in the Union, but there are several good establishments for the blind and for the deaf and dumb, while the government has founded two excellent institutions for juvenile feebleminded patients. So far only the fringe of the problem of the chronic sick has been touched, and so long as hospitalization remains in the hands of the provincial authorities, without adequate funds for proper organization, it is unlikely that the much wanted improvements will be forthcoming.

Deaths in the Profession

South Africa is greatly understaffed with physicians, there being about 1 for every 4,000 people. Our annual recruitment from the universities is approximately 25, and nowadays, contrary to what occurred before 1910, we obtain comparatively few physicians from the outside. The loss through death among our practitioners is relatively large. Last month, for example, seven died, only three of them being seniors in the profession. Among these the oldest, though perhaps not the best known, was Dr. D. B. Logie, who had qualified in 1873 and had been practicing in this country since 1878. He had been in bad health for several years and since 1902 had practically given up practice. Dr. R. Mackenzie of Johannesburg was a better known practitioner and our foremost authority on hospitalization. He was for years medical superintendent of the Johannesburg Hospital. On his retirement under the age limit, some years ago, he devoted himself to consulting dermatologic practice and quickly established a large consulting practice. His death, unexpectedly, from a subphrenic abscess came as a shock to the profession, which he had served for many years as member of the medical council, examiner, and member of the federal council of the medical association. Among the more junior members of the profession whose deaths are recorded are Dr. P. H. Henson of Fort Victoria, Southern Rhodesia, and Dr. A. C. Harrison. The latter was well known as an assayer and metallurgist before he took up medicine, and his brilliant academic career foreshadowed an equally successful professional activity, which has been cut short by his sudden and untimely death. Other medical men whose deaths are recorded this month are Dr. Redelinghuys, Dr. Kennedy, Dr. Kitchin and Dr. J. A. Kennedy, all well known general practitioners.

Smallpox Vaccination in Infancy

As a result of studies by the investigating commission, to which reference was made previously (The Journal, July 26, p. 280), the public health service sent a circular letter to all physicians of the Netherlands, calling attention to the advantages of smallpox vaccination during the first year of life. Statistics have shown that, during the first twelve months of life, postvaccinal encephalitis develops much less frequently. Furthermore, the local accidents of vaccination are much less when vaccination is applied during the first year of life. The periods most favorable for vaccination are May and December. Children who have not fully recovered from an infectious disease, and likewise children who are living in an environment in which infectious diseases have recently occurred, should not be vaccinated as yet. The circular letter concludes with an appeal to the physicians of the Netherlands that they adopt this method, as it is the only method that will afford protection against an epidemic of smallpox and that will, at the same time, reduce the dangers of encephalitis.

Aid for Tuberculous Employees

Dr. Jitta sent recently to the International Bureau of Hygiene a communication on the various aspects of the crusade against tuberculosis in the Netherlands. 1. The Netherlands does not have compulsory insurance against tuberculosis. A number of societies assume as their task the providing of aid for their members who have tuberculosis, and also aid for their families. Some of these societies are: (*a*) Herwonnen Levenskracht (recuperated vitality), a Catholic society for combating tuberculosis, which aids its members and persons of their family affiliated with the federation of Catholic artisans, or belonging to the Catholic societies of workmen. (*b*) The general fund for miners, which grants medical aid to miners and their families. The dues are paid partly by the workmen and partly by the mine owners (50 per cent each). (*c*) The railway employees' association for combating tuberculosis. (*d*) The association named "Draagt elkanders Lasten" (bear one another's burdens), established on a Christian basis. (*e*) The sanatorium for the marine. (*f*) "Willen is kunnen" (Qui vult, potest), the association for the municipal employees of Amsterdam, which has its own sanatorium. 2. There are some industrial organizations that take back into their service workmen who have completed a course of treatment, and grant them favorable conditions of work. 3. The following industries have medical services recognized by the committee of the insurance bank of the kingdom:

Werkspoor (construction work), Amsterdam and Zuilen.
Kromhout Motorfabriek, Amsterdam and Zuilen.
"Willem-Sophie" Coal Mine, Heerlen.
Feyenoord (construction work), Rotterdam.
"Oisterwijk" Leather Factory, Oisterwijk.
Heemaf (electrical apparatus), Hengelo.
Artificial Silk Works; Arnhem, Ede and Hillegersberg.
State Mines, Heerlen.
"Orange-Nassau" Mine, Heerlen.
Wilton (builders), Rotterdam.
Lips (manufacturers of safes), Dordrecht.
The Philips Factories (electric lamps), Eindhoven.

(*a*) According to a labor decree, physicians may, in accord with the regional heads of inspection of labor, prescribe the conditions for the employment of women and for the employment of those who are not yet considered as adults. (*b*) Some industries provide for the inspection of dwellings; but there is as yet no extensive control of hygiene in general, with the exception of the Philips factories. 4. There are as yet no industries having hospitals or sanatoriums of their own, although there are societies having a sanatorium for the use of their members.

Vaccination Against Tuberculosis

Dr. Heynsius van den Berg communicated to the International Convention for the Combating of Tuberculosis, held in Oslo, observations made in the Netherlands, which were scientifically established, presenting in parallel series groups of vaccinated and of nonvaccinated children living in the midst of a tuberculous environment. There were 3.8 per cent of deaths from tuberculosis among the vaccinated group and 52.3 per cent of deaths from tuberculosis among the nonvaccinated group, which is proof that the resistance of vaccinated children is notably increased.

The Incidence of Poliomyelitis

The International Bureau of Public Hygiene has published an official report on the cases of poliomyelitis observed in the country in 1929 and 1930. In 1929 there were 507 cases of poliomyelitis notified, 123 from South Holland, 102 from Limburg, 68 from North Holland, and 49 from North Brabant. The widest incidence of the disease occurred in October. In 1930, the number of cases showed an increase beginning with the month of May. Whereas in 1929 the regions most affected were located in the southern and the eastern parts of the Netherlands, this year the central area is the region most affected; more particularly, South Holland and Gelderland. A circular letter addressed in June, 1930, by the "inspector general" of the public health service, to all the medical practitioners of the Netherlands, acquainted them with the means at their disposal when they discover a case of poliomyelitis. The country was divided into twenty-three districts in each of which a specialist in neurology was designated to assist the general practitioners. The latter could call in the neurologist for a consultation whenever they encountered a suspicious case, the expense of the consultation being charged to the central government. A card attached to the circular letter gave the general practitioner the name, address and telephone number of the neurologist to whom he should address himself in case of need. The circular letter contained also information in regard to the chief clinical facts known with reference to the disease, which served to aid in the diagnosis of suspected cases and in controlling their development.

Owing to this organization, the diagnosis could be rapidly established and the proper treatment could be instituted without delay. Convalescents' serum, for securing which special regulations were established, would be sent to the neurologist, on request by telegraph, by the Central Laboratory at Utrecht. The attending physician and the neurologist unite their efforts to get the patient admitted to the hospital where the best conditions for recovery are obtainable.

Traffic Accidents in Amsterdam

During the previous quarter, the number of traffic accidents in Amsterdam reached 1,547, as compared with 1,430 for the corresponding period of last year, an increase of 8 per cent. The grave accidents gave a total of 181, as against 108 last year. Thirteen of the accidents resulted fatally and in eighty-six further cases the injuries were very serious. About 72 per cent of the accidents were due to the negligence of the drivers of the vehicles and 10 per cent were due to the carelessness of pedestrians. A comparative study of fatal and grave accidents in various cities follows: Amsterdam has 218.2 accidents per 100,000 inhabitants; London, 726.2; Liverpool, 514.2; Munich, 476.1, and New York, 903.3. Paris reports 105.4 accidents per 100,000 of population, but all the slighter accidents have been eliminated.

Mental Abnormalities in Women, Associated with Reproductive Processes

Prof. Hugo Sellheim, director of the Universitäts-Frauenklinik, in Leipzig, presented recently before the Juristisch-medizinische Gesellschaft of Leipzig a paper on "Influence of the Reproductive Cycles on the Sense of Moral Responsibility Displayed by Women." Three different branches of knowledge are concerned with researches on the influence of the reproductive phases in women, with all their anomalies and peculiarities —namely, gynecology, including obstetrics; psychiatry, and jurisprudence. Criminal manifestations are, on the whole, less marked in women than in men, but certain criminal acts are more common in women than in men; more particularly, certain acts that in their origin are associated with sex life and family life in general. In any event, the phases in the reproductive or sex life of woman affect increasingly psychic manifestations or disturbances in the various cycles of life. The psychic disturbances to be noted vary greatly in nature and in duration, and questions pertaining to the more or less restricted sense of moral responsibility must be studied in the light of the influences mentioned.

In unusual emotional acts of women, and especially in connection with misdemeanors and crimes, a careful inquiry must be made into the existing physical conditions that constitute the background or that may have had a precipitating influence.

It is not always the extreme degrees of mental exhaustion and excitement that demand consideration in the daily life of woman; also the emotional disturbances that appear without apparent cause require intelligent analysis. Under the influence of generative processes, ranging from puberty to the climacteric, or beyond, there appear from time to time, sometimes with frequent repetitions but often with considerable regularity, fear, irresoluteness, increased irritability, loss of memory—in fact, women may appear to be entirely changed in character.

Sellheim, therefore, recommends that women, burdened with the tasks of reproduction and often with outside occupational cares, be judged with the greatest forbearance. Their emotional disturbances cannot be understood without an open mind and a kindly appreciation of woman's character based on a knowledge of woman's bodily peculiarities.

Assembly of Society of German Scientists and Physicians

At a joint meeting of the two main sections of the ninety-first session of the Gesellschaft Deutscher Naturforscher und Aerzte, in Königsberg, Oct. 6-8, 1930, A. Dietrich of Tübingen spoke on the "Essential Nature and Causes of Thrombosis and Embolism." The mechanism of the origin and the growth of a thrombus is conditioned by the combined action of several factors; the chief influence is a change in the relations of vessel wall, blood and circulation. Thrombosis is not a purely mechanical process consisting merely of an elimination from the blood, but it is a reactive process precipitated by a disturbance of the relation between blood and vessel wall, in which one or the other may become abnormally dominant. The danger from embolism is slight in local thrombi of limited extent but is great in migratory thrombi, especially if a sudden change in the relation of vessel wall and blood should lead to a rapid discharge of loose thrombic masses. A. Mayer of Tübingen discussed the theme from the standpoint of the gynecologist. Puerperal thrombosis appears to be more frequent than postoperative thrombosis. Embolism, however, is more frequent after operations than post partum, and more frequent after occult and bland thromboses than after manifest and infectious thromboses. The differential diagnosis between infectious and bland thromboses is difficult to apply clinically. There is no form of prophylaxis that can be relied on with certainty. As regards therapy, the treatment of thrombosis with ambulatory bandages deserves attention; in embolism the Trendelenburg operation is a distinct step forward, though the indications for the operation are extremely difficult to determine. Zwerg of Königsberg spoke on the present status of "Radium Surgery in Its Application to Malignant Tumors." He described how, by the combined use of operation and the introduction of radium containers, most excellent results can be secured, though the treatment is limited essentially to certain tumors. For instance, highly favorable results are obtained in cancer of the bladder, whereas cancer of the prostate does not offer a favorable field. Cancer of the rectum should, as far as possible, be operated on, and the radium containers inserted afterward. With these measures, the results are much better than with any other mode of treatment. Cancer of the uterus should not be treated with radium—treatment with roentgen rays is by far more successful. The next topic was "The Roentgen Diagnosis of the Large Intestine." H. H. Berg of Berlin demonstrated how, with the aid of the roentgenogram, disorders of the large intestine can be recognized and differentiated. H. Chaoul of Berlin presented a paper on "The Roentgen Diagnosis of Tumor Formation in the Large Intestine." By means of roentgenologic examination of the large intestine pathologic organic changes can be diagnosed with immeasurably greater certainty than by the sole utilization of anamnestic and clinical methods, which commonly lead to atypical results.

At another session, M. Askanazy of Genoa spoke on "Benign Disorders of the Mammary Gland in Their Relations to Cancer of the Breast." The benign disorders that may lead to cancer consist of certain malformations and inflammations, a fibrosis associated with cyst formation, and certain benign growths. It is not certain that any one of them will lead to cancer. Cysts of the breast signify neither inflammation nor tumor. They are to be regarded merely as evidence of a peculiar irritability of the epithelium of the mammary gland. The epithelium may proliferate with or without metaplastic change and may develop into cancer. It has not been demonstrated that parasitic influence plays any part in the development of cancer of the breast in man. There may be marked predisposition of the organ, but that does not suffice for the formation of cancer.

Marriages

R. M. Baldwin, Madison, Wis., to Miss Lorenchia Christensen of Beloit, in Wilman, Minn., September 13.

Thomas Henning Anderson, Lawrenceville, Va., to Miss Ruth Sullenberger, of Monterey, September 25.

Adolph Gottlieb Kammer, Belleville, Wis., to Miss Margaret M. Carrol of Philadelphia, September 6.

Robert E. Burns to Dr. Charlotte J. Calvert, both of Madison, Wis., in Minneapolis, September 16.

Earl D. McConnell, Darlington, Wis., to Miss Mary E. Cox of Platteville, in Madison, September 2.

N. Warren Bourne to Miss Evangeline Lueth, both of Milwaukee, at Manitowoc, September 16.

Henry Charles Davis, Grundy, Va., to Miss Vida Louise Looney of Welch, W. Va., August 30.

Lewis Abner Law, Alberta, Va., to Miss Evelyn Virginia Thompson of Lexington, September 3.

Thomas Boyd Washington to Mrs. Effie Daniel Ansley, both of Richmond, Va., September 1.

Leo Frank Chess, Reed City, Mich., to Miss Thelma Heck of Blairstown, Iowa, September 5.

Fred O. E. Eggert, Chicago, to Miss Helen Jane Duncan of Appleton, Wis., September 10.

Charles R. Anderson to Miss Lena R. Riley, both of Winchester, Va., August 21.

John Willard Travell to Mrs. Edith Talcott Bates, both of New York, August 14.

Carlton J. Ryan to Miss Elvira E. Dashner, both of Adams, Wis., August 26.

Deaths

Preston Manasseh Hickey ⊕ since 1922 professor of roentgenology, University of Michigan Medical School, Ann Arbor, died, October 30, aged 64. Dr. Hickey was born in Ypsilanti, Mich., Dec. 3, 1865. He graduated from the University of Michigan in 1888, and the Detroit College of Medicine, in 1892. Dr. Hickey was professor of roentgenology at his alma mater from 1909 to 1922. He was a lieutenant colonel during the World War and a consultant in roentgenology in the American Expeditionary Forces, a member of the American College of Physicians, the American College of Surgeons, the Radiological Society of North America, the American College of Radiology, and member and past president of the American Roentgen Ray Society. He was roentgenologist to the Children's Hospital, Harper Hospital, Receiving Hospital, Detroit, and the University Hospital, Ann Arbor. Dr. Hickey was one of the pioneer radiologists. He was largely responsible for increasing the scope of the radiologic exhibit which has become outstanding at the annual sessions of the American Medical Association. He was instrumental also in the establishment of the Henry Simpson Memorial Institute for Medical Research at Ann Arbor.

Derrick Tilton Vail, Sr. ⊕ Cincinnati; Miami Medical College, Cincinnati, 1890; emeritus professor of ophthalmology, University of Cincinnati College of Medicine; member and past president of the American Academy of Ophthalmology and Oto-Laryngology, member of the American Ophthalmological Society and the American College of Surgeons; consulting ophthalmologist to the Cincinnati General Hospital; proprietor of a hospital bearing his name; aged 66; died, October 29, of heart disease.

Lever Flegal Stewart ⊕ Clearfield, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1910; member of the American College of Surgeons; served during the World War; aged 42; died, July 22, in the Jewish Hospital, Philadelphia, of cholelithiasis.

Dean Spencer Drake, White River Junction, Vt.; University of Vermont College of Medicine, Burlington, 1904; member of the Vermont State Medical Society; served during the World War; aged 58; died, August 30, in Monson, Mass., of angina pectoris.

Luther F. Crawford, Tyrone, Pa.; Eclectic Medical Institute, Cincinnati, 1890; member of the Medical Society of the State of Pennsylvania; veteran of the Spanish-American War; aged 71; died, August 22, in Pittsburgh, of heart disease.

Fred Fisher, Jr. ⊕ Erie, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1913; owner of an eye, ear, nose and throat hospital; aged 39; died, September 2, in the Augustana Hospital, Chicago, of acute appendicitis.

Hollis Goodell Dean ⊕ Fredonia, Pa.; Chicago Homeopathic Medical College, 1891; Hahnemann Medical College and Hospital, Chicago, 1905; aged 65; died, September 1, in the Mercer (Pa.) Cottage Hospital, of angina pectoris.

Charles Philip McCabe, Greenville, N. Y.; Albany Medical College, 1883; member of the Medical Society of the State of New York; aged 74; died, in September, in Albany, of chronic myocarditis and cerebral arteriosclerosis.

Charles Henderson Chandler, Fort Fairfield, Maine; Tufts College Medical School, Boston, 1911; member of the Massachusetts Medical Society; aged 44; died, September 5, of chronic myocarditis and bronchopneumonia.

John Claudius Young, Cuba, N. Y.; University of Buffalo School of Medicine, 1871; member of the Medical Society of the State of New York; aged 85; died, October 4, of chronic bronchitis and myocarditis.

William W. Pennell ⊕ Mount Vernon, Ohio; University of Wooster Medical Department, Cleveland, 1875; aged 77; died, September 30, in the Christ Hospital, Cincinnati, of myocarditis and prostatitis.

James William McDonald, Worcester, Mass.; University of Maryland School of Medicine, Baltimore, 1902; member of the Massachusetts Medical Society; aged 60; died, September 26, of heart disease.

Francis Rupright, East Gilead, Mich.; Indiana Eclectic Medical College, Indianapolis, 1888; aged 66; died, September 28, in the New Borgess Hospital, Kalamazoo, of cerebral hemorrhage.

Sarah J. McNutt, Albany, N. Y.; Woman's Medical College of the New York Infirmary for Women and Children, 1877; aged 91; died, September 10, of arteriosclerosis and myocarditis.

Charles P. Peterman, Brooklyn; Long Island College Hospital, Brooklyn, 1883; member of the Medical Society of the State of New York; aged 73; died, October 6, of heart disease.

Thomas Wilson Burrows, Chicago; Rush Medical College, Chicago, 1887; on the staff of a hospital bearing his name; aged 68; died, September 26, in Utrecht, Holland, of heart disease.

George F. Mead, Pinckneyville, Ill.; St. Louis College of Physicians and Surgeons, 1892; member of the Illinois State Medical Society; aged 66; died, October 1, of heart disease.

Joseph Fernand Lescale, New Orleans; Medical Department of the Tulane University of Louisiana, New Orleans, 1895; aged 58; died, September 21, of myocarditis and nephritis.

George O. Maskey, Upper Sandusky, Ohio; Medical Department of Western Reserve University, Cleveland, 1882; aged 74; died, in October, of cerebral hemorrhage.

Louis Henry Warner, Newark, N. J. (licensed, New York, 1893); aged 69; died, October 4, in the Homeopathic Hospital, East Orange, of acute intestinal obstruction.

William J. Davis, Pottstown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1889; also a druggist; aged 62; died, September 11, of nephritis.

Shelby Cullom Shurick ⊕ Wrangell, Alaska (licensed, Alaska, 1909); served during the World War; aged 53; died, July 13, of tuberculous laryngitis.

J. Paul Harvill, Nashville, Tenn.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1901; aged 58; died, October 6, of angina pectoris.

Elmer Ellsworth Best, Los Angeles; College of Physicians and Surgeons, Chicago, 1899; aged 72; died, August 29, of hemorrhage, following a fall.

Clarence Elton Wheeler, Milwaukee; Milwaukee Medical College, 1901; aged 59; died, August 25, of cerebral hemorrhage and cirrhosis of the liver.

Asa Bennett Stratton, Exeter, Neb.; Central Medical College of St Joseph, Mo., 1895; aged 69; died, August 31, of cerebral hemorrhage.

Ralph Parker Dowd ⊕ Fisher, Ill.; Medical College of Ohio, Cincinnati, 1893; aged 64; died, September 29, of arteriosclerosis.

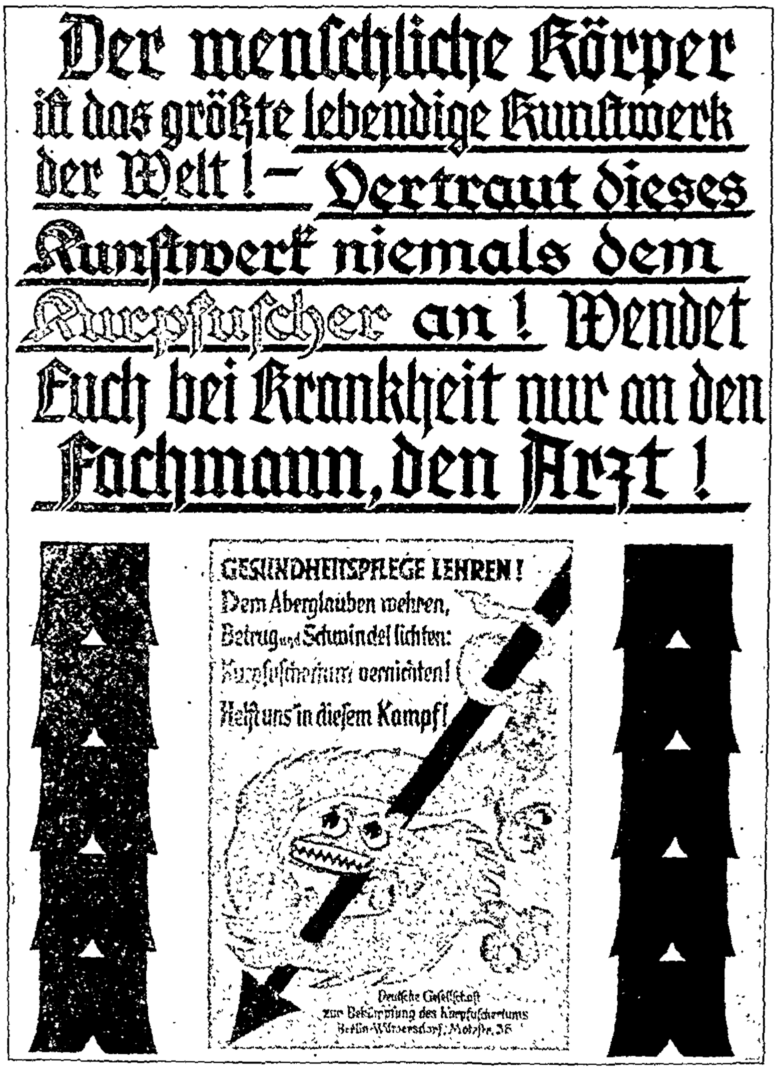
Charles Edward Williams, Boston; Tufts College Medical School, Boston, 1900; aged 75; died, September 23, of cerebral hemorrhage.

Bureau of Investigation

MORE MISBRANDED NOSTRUMS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

Old Mission Laxative Cold Tablets.—The S. Pfeiffer Manufacturing Company, St. Louis, Mo., shipped in January, 1929, into Indiana a quantity of Old Mission Laxative Cold Tablets that were declared misbranded. The tablets were reported to contain, chiefly, acetanilide, a cinchonine compound, extracts of laxative plant drugs, terpin hydrate, oil of wintergreen, and a small amount of potassium bromide. The claims that this was a remedy for coughs and influenza were declared false and fraudulent and in September, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed. — [*Notice of Judgment 16790; issued May, 1930.*]



Der menſchliche Körper iſt das größte lebendige Kunſtwerk der Welt! — Vertraut dieses Kunſtwerk niemals dem Kurpfuſcher an! Wendet Euch bei Krankheit nur an den Fachmann, den Arzt!
GESUNDHEITSPFLEGE LEHREN!
Dem Aberglauben wehren,
Betrug u. Schwindel ſichten:
Kurpfuſchertum vernichten!
Helft uns in dieſem Kampf!
Deutſche Geſellſchaft zur Bekämpfung des Kurpfuſchertums Berlin-Wilmersdorf, Motzſtr. 38

This is a monotone reproduction of a four color (red, green, yellow and black) poster issued by the German Society for Combating Quackery. A free translation reads: "The Human Body is the Greatest Work of Art in the World! Do Not Entrust this Work of Art to a Quack! During Illness Consult only a Reputable Physician!"

"To Teach Hygiene!
"To Combat Superstition!
"To Expose Frauds and Swindles!
"To Eradicate Quackery!
"Help Us to Attain These Aims!

A. D. S. Cold and Grippe Tablets.—The Vadsco Sales Corporation, Long Island City, N. Y., shipped into Illinois in January, 1929, a quantity of A. D. S. Cold and Grippe Tablets that were declared misbranded. The tablets were found to contain acetanilide, quinine sulphate, aloin, camphor, red pepper and extract of podophyllum. The claim that the product was a remedy for influenza was declared false and fraudulent; the statement that each tablet contained 2 grains of acetanilide when, as a matter of fact, it contained less than that constituted further misbranding. In April, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16799; issued May, 1930.*]

Astyptodyne and Astyptodyne Cough Syrup.—The Astyptodyne Chemical Company, Wilmington, N. C., shipped in January and December, 1928, and January, 1929, into South Carolina quantities of Astyptodyne and Astyptodyne Cough Syrup, both of which were declared misbranded. Astyptodyne was found on analysis to consist of pine oil, while the Astyptodyne Cough Syrup consisted of sugar syrup and 2 per cent of pine oil. The claims for Astyptodyne, to the effect that it was a remedy for old ulcers, sores, wounds, skin eruptions, itch, eczema, neuralgia, etc., and the claims for Astyptodyne Cough Syrup, to the effect that it was a remedy for coughs, sore throat, bronchitis, whooping cough and croup, were declared false and fraudulent, while the further claim that Astyptodyne was antiseptic and germicidal was declared false and misleading. In June, 1929, the court ordered that the product be destroyed.—[*Notice of Judgment 16800; issued May, 1930.*]

Nip-a-Co Capsules. — Frederick Stearns and Company of Detroit shipped in September, 1928, to West Virginia a quantity of Nip-a-Co Capsules that were declared adulterated and misbranded. Analysis showed the capsules to contain, essentially, acetanilide, cinchonine sulphate, magnesium carbonate, red pepper, extracts of plant drugs including podophyllum and jalap, traces of salicylic acid, and alkaloids of aconite. It was declared adulterated because the label declared that each capsule contained cod liver oil extract, which the federal chemists reported it did not; this claim also constituted misbranding. Further, the therapeutic claims that this was a remedy for neuralgia and influenza were declared false and fraudulent. In May, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16851; issued July, 1930.*]

Pronto.—The National Drug Products, Inc., Albany, N. Y., shipped into Florida in January, 1929, a quantity of Pronto that was declared misbranded. The government chemists reported that it consisted essentially of ammonium salicylate, glycerine, small amounts of potassium, antimony and free ammonia, traces of magnesium, chlorides and sulphates, and an extract of a laxative plant drug. The claims that it was a remedy for influenza, sore throat, chronic constipation, bronchitis, etc., were declared false and fraudulent, and in October, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16869; issued July, 1930.*]

Correspondence

THE MENACE OF THE MEAT DIET

To the Editor:—In a recent editorial (Is a Meat Diet a Menace? The Journal, September 20, p. 866) you conclude by inference that a meat diet will not injure the kidneys and cite the observations at the Russell Sage Institute of Pathology on two arctic explorers as experimental support for your views. So far as I can see, the only conclusion properly deducible from these observations is that an average intake of meat protein of from 100 to 140 Gm. daily for one year causes no detectable kidney damage. What might happen after two or more years on such a diet remains unknown.

The experiment of Newburgh, Falcon-Lesses and Johnston (*Am. J. M. Sc.* **179**:305 [March] 1930), in which evidence of kidney damage in man was obtained on a diet containing 330 Gm. of meat protein per diem in less than six months, indicates that renal injury may be caused by diets sufficiently high in meat protein. Further, Newburgh and his co-workers (Newburgh and Curtis: *Arch. Int. Med.* **42**:801 [Dec.] 1928) have succeeded in producing chronic nephritis in laboratory animals by high meat diets.

However, it remains to be determined (1) whether the animal nephritis produced by meat protein is pathologically analogous to chronic nephritis in man, (2) whether human beings ordinarily, or even occasionally, eat enough meat protein to cause chronic nephritis, and (3) whether the meat consumption of patients with chronic nephritis has been at such levels as might cause nephropathy. Meat protein might cause chronic nephritis and yet not be the usual etiologic agent because not ingested at appropriate levels.

In contrast to the studies of Thomas and Heinbecker, who found no unusual incidence of kidney disease among Eskimos, must be placed the investigations of Hindhede, who finds that chronic nephritis is most common in people who eat much animal food.

The entire problem, I believe, should be kept *sub judice* until the foregoing questions are more fully answered.

Mark Falcon-Lesses, M.D., Boston.

THE "MEDICAL INTERPRETER"

To the Editor:—Kindly give publicity to the following:

Under date of April 13, 1930, I received a letter from Dr. Arthur F. Stotts, Colonel, Medical Reserve Corps, Galesburg, Ill., stating that a representative of the *Medical Interpreter* had informed him that the *Medical Interpreter* was published in conjunction with the Public Health Service and the Army Medical Library, and requesting information in regard to the matter. Under date of September 2 I had a similar letter from Dr. W. L. Casler, Marquette, Mich., and under date of October 13, a similar one from Dr. Ewald Hermann.

These letters suggest that there is a systematic effort to make it appear that the *Medical Interpreter* bears an official relationship to the public health services and especially to the Army Medical Library.

The facts are that two employees of the *Medical Interpreter*, women without medical training so far as I know, utilize the Army Medical Library as all citizens may. I understand that their work is the preparation of abstracts and bibliographies for subscribers to the *Medical Interpreter's* service.

Any representation that the *Medical Interpreter* shares its profit, if any, with the Office of the Surgeon General of the Army or with the Army Medical Library, or that they or either of them is associated with it, interested in it, or even gives it approval, is false and misleading.

M. W. Ireland, M.D., Washington, D. C.
Surgeon General, United States Army.

"SOMNOFORM"

To the Editor:—I have recently received from the Stratford-Cookson Company of Philadelphia an advertisement of "Somnoform." The formula given for "Somnoform" is chloride of ethyl, 83 per cent; chloride of methyl, 16 per cent; bromide of ethyl, 1 per cent. Below this formula it is asserted that "the record of Somnoform for safety is without equal." If such is the case the record must be regarded as a pure piece of good fortune, for two at least of the ingredients of "Somnoform" have a toxicity which renders them unfit for use as anesthetics. The poisonous character of methyl chloride has been sufficiently demonstrated by the refrigerator cases in Chicago. Although the amount of ethyl bromide in the mixture is small, there are general grounds for believing that the toxicity of the substance is high. Ethyl chloride is, of course, a commonly used and convenient anesthetic, but it possesses to a considerable degree dangers of the same type as chloroform. As much safer anesthetics, such as ether, ethylene and nitrous oxide, are available, there is really, in my opinion, little justification for the continued use of ethyl chloride as an anesthetic at all.

Yandell Henderson, Ph.D., New Haven, Conn.

[Note.—In 1919 the Council on Pharmacy and Chemistry declared "Somnoform" inadmissible to New and Nonofficial Remedies because, in the absence of acceptable evidence showing its exceptional safety and value, the claims made for it were held to be unwarranted and because the name of the mixture is not descriptive of its composition.—Ed.]

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

OVARIAN EXTRACTS AND HORMONES AND SEXUAL FRIGIDITY

To the Editor:—Will you please explain the difference between the newly discovered sex hormone and the older substances, as ovarian extract and corpus luteum? What is the recognized name for the former? How does the former differ from the latter in action in the female? Which pharmaceutic company manufactures the former? What is the treatment for female frigidity when it is congenital and hereditary? The patient has one child. Both she and her husband are intelligent, but I foresee a family separation unless this matter is corrected. There is no anatomic abnormality in the female and she is willing to do anything possible to adjust this matter. Please omit name. M.D., New York.

Answer.—It is not surprising that some physicians have a hazy conception of the differences between the newly discovered female sex hormones and other hormones which are produced in the female genitalia. Even authorities are not agreed on the differences. Frank (The Female Sex Hormone, 1929) points out that many investigators believe there is only one female sex hormone which is responsible for all the sex phenomena including the estrual cycle in the lower animals and the menstrual cycle in the anthropoids. Others believe that in addition to the ovarioplacental hormone there is a second inhibitory one which arises in the corpus luteum at the same time the female sex hormone is being secreted. This special corpus luteum hormone regulates the rhythm of the cycle and sensitizes the uterine mucous membrane. These researches indicate that the corpus luteum secretes two different hormones simultaneously. Allen and Corner (*Proc. Soc. Exper. Biol. & Med.* **27**:403 [Feb.] 1930) recently demonstrated a substance in the corpus luteum of pigs which, when injected, will maintain pregnancy to full term in rabbits spayed at the eighteenth day after mating.

The graafian follicle and its successor the corpus luteum are the sources of the hormones which bring about puberty and the continuation of the menstrual cycle. The hormone from the follicle prepares the uterus for menstruation while the corpus luteum continues and adds to this hormonal action. By means of this the uterine endometrium is prepared for the reception of a fertilized ovum. Papanicolaou (The Journal, May 8, 1926, p. 1422) states that there is a hormone produced by the corpus luteum which is antagonistic to the female sex hormone. He calls it the "luteal hormone" and its function is to inhibit further maturation of graafian follicles during the periods of physiologic amenorrhea between puberty and the menopause.

The female sex hormone is found in the follicle fluid, the corpus luteum, the placenta, the blood, the urine of normal women, the urine of pregnant women, the feces, the bile, the blood of males and other tissue fluids. It may also be found in plants. Excellent pioneer work on the isolation of this principle has been done by E. A. Doisy, who has coined for it the nonproprietary name "Theelin" (The Journal, May 10, 1930, p. 1523).

The anterior pituitary hormone recently discovered in the urine by Aschheim and Zondek differs from the female sex hormone found in the unruptured follicle, the corpus luteum and the placenta in the following way: The pituitary hormone influences the ovaries so as to cause the ripening of immature follicles and the formation of corpora lutea. For this reason Zondek calls the anterior pituitary gland "the motor of ovarian activity." It has no direct effect on the uterine and vaginal mucosa. On the other hand, the female sex hormone has practically no effect on the follicular apparatus but it does have a distinct stimulating influence on the lower genital tract, bringing about estrus in castrated mice and rats. The anterior pituitary hormone is most likely more important in sex physiology than what has hitherto been considered as the characteristic female sex hormone.

Three biologic tests have been devised, based on these hormones. In one, adult spayed mice are employed and estrus is produced by the female sex hormone. In the second, noncastrated infantile mice are used and an effect is produced in the uterus and vagina through the ovary. The hormone responsible for this presumably comes from the anterior pituitary. The third test consists of injecting blood serum from pregnant women into immature virgin animals and producing changes in the uterus and estrus.

Ovarian extract is a mixture of everything in the ovary—graafian follicle, corpus luteum, stroma. It has practically no specific action (The Journal, June 21, p. 1997).

Commercial extracts of the female sex hormone are made in this country by E. R. Squibb and Sons under the trade names of Ovarian Hormone-Squibb and Amniotin-Squibb (The Journal, May 18, 1929, p. 1678) and by Parke, Davis & Company under the trade name of Estrogen. European preparations and their manufacturers are as follows: Menformon old and Menformon new, made by Degewop; Sistomensin and Agomensin, made by Ciba. Other foreign extracts of the female sex hormone are Folliculin and Hormovar.

The prices for these extracts are high and thus far the clinical results obtained with them have not been striking. Their use is still in the experimental stage, although some women may have been benefited by them. In many instances these products when given hypodermically produce unpleasant local and systemic reactions. Recently Allen and Baker (*Am. J. Obst. & Gynec.* **20**:85 [July] 1930) reported that the administration of amniotin-Squibb in gelatin pessaries by the vaginal route was not only less objectionable but more effective than subcutaneous injections of water preparations.

The treatment of frigidity in the female is usually entirely unsatisfactory. A large proportion of women have absolutely no libido and little can be done for most of them. In many cases there is a psychic factor which can or cannot be overcome. In most instances the wife has no real deep love for her husband; but on the other hand frigidity may be present even when sincere love is a certainty. Drugs are almost entirely useless. Occasionally hot tub baths before going to bed for the purpose of producing a hyperemia are helpful. Fewer matrimonial disagreements would arise if frigid women would refrain from confessing their sexual anesthesia to their husbands.

ACUTE SWELLING OF THE TONGUE

To the Editor:—A man, aged 45, weight 220 pounds (100 Kg.), health perfect and without previous sickness, came to me with a swollen tongue. The swelling began about 6 p. m., and he came to see me two hours later with the tongue so swollen that it was difficult for him to talk. He said that at first it felt as if there were a small pimple on the outside of the tongue. By midnight it commenced subsiding and he soon was relieved. He did not complain of pain or tenderness. There was no discoloration. The temperature and pulse were normal. I would appreciate a diagnosis and discussion of the treatment. Please omit name. M.D., Tennessee.

Answer.—An acute swelling of the tongue might result from an injury such as biting it, which may have been forgotten. It might have been an angioneurotic edema or urticaria, in which one may obtain a history of previous attacks. An acute local inflammatory condition might cause the symptoms. This is perhaps the most likely cause in the absence of a history of the other conditions. However, it is rather unusual for infection to develop and subside suddenly without other evidence than the feeling of a pimple, which may have been the result of the swollen tongue projecting between two teeth.

Occasionally, with an acute tonsillitis, an abscess may develop in a crypt producing an acute local edema on one side of the tongue. This would promptly subside with spontaneous drainage of the crypt. Such an infection might occur in any of the small glands or lymph follicles in the mouth. Pain is not always present. The teeth should be examined for abscesses, since they may cause a submaxillary inflammation of the glands, causing swelling of the tongue.

The treatment depends on determining the cause. In early infections with edema, incision should be avoided until there has been a sufficient time for a protective zone of round cell infiltration with evidence of abscess formation. Intermittent large hot moist applications to the region involved are indicated. Continuous hot applications may aggravate the edema, which may extend to the larynx.

A Ludwig's angina may result when there is a cellulitis extending to the submaxillary triangles from the floor of the mouth. This has a high mortality and requires extensive operative drainage to prevent its extension.

All patients with the symptoms of the swelling described should be carefully observed with frequent blood counts until relief has been obtained. When abscess formation is suspected, it should be incised.

BURN WITH TETRA-ETHYL LEAD OR ETHYLENE DIBROMIDE

To the Editor:—Recently one of our laboratory men was burned on the dorsal medial surface of his left hand with tetra-ethyl lead used in making ethyl gasoline, and the process is called "knock rating." When he was questioned concerning the burn the man related: "It feels like my hand had been stuck in flame of fire and just as soon as I put it in water and wash off the fluid, the sensation disappears but the burn is present." The burn that he had was of first degree nature, acute hyperemia. I will appreciate it if you will give me the antidote or neutralizing agent for this type of burn and the best way to handle it in regard to treatment.

R. Henry Harrison, Jr., M.D., Ingleside, Texas.

Answer.—Tetra-ethyl lead is not a skin irritant. Exposure in the manner indicated may be expected to lead to no more skin irritation than from an equal amount of gasoline. Frequently there is associated, with the tetra-ethyl lead, ethylene dibromide, which is known to possess some irritant properties. It is likely that the burn referred to is due to the latter substance. Immediately following exposure, any worker should apply kerosene or some similar substance. This application is not so much to prevent skin irritation as to prevent absorption, since both tetra-ethyl lead and ethylene dibromide are absorbable through this portal. Following this step, the portion of the body so exposed and so treated should be washed with soap and water in order to remove the kerosene containing these chemicals. No other treatment is ordinarily required, but, if skin irritation requires further attention, such conditions may be treated as any other burn of equal severity.

TREATMENT OF COLITIS

To the Editor:—A patient of mine was taken sick with a hard chill, June 24, and immediately developed a severe colitis. By using the usual treatment I soon got the bowels checked, but I cannot get them regulated. The patient has been kept on a soft diet until almost starved, but the bowels would immediately break loose if anything but soft diet was given. When the bowels are checked, impactions form which require an opiate to move as he has been sick so long, he has no strength to pass the impaction, and the cramping is intense when the bowels move. Is there any treatment for these impactions, which form in the bowels about every six or seven hours? It is impossible for the patient to endure the pain without a hypodermic of morphine after an enema. Is there any treatment for it? The bowels seem to be paralyzed and the patient is growing weaker each day. Will the morphine have a tendency to constipate? The patient became addicted while the colitis was so bad. I would be more than glad if you could suggest something to do as I am at my wits' end. Please omit name. M.D., Illinois.

Answer.—It would be best to continue on a smooth diet, a diet the particles in which are so fine that they could go or have gone through a sieve, until the patient is well beyond the present stage. Then a gradual return to general diet should be attempted by adding tender cellulose-containing vegetables, such as spinach, cauliflower and asparagus, then bran, and later the coarser vegetables. Oils should be used freely from above as well as from below. Liquid petrolatum, in doses of a tablespoonful or two, may be taken morning and evening and half an hour before dinner and supper as well. The oil enema (as much warm olive oil as the patient can retain over night) should be repeated every evening for several days. If enough oil is used, the hard fecal masses cannot form; and, if any are passed during this treatment it is reasonable to assume that they have been in the bowel prior to it.

If, in spite of the liquid petrolatum and the oil enemas, spontaneous bowel movements do not occur, then a course of castor oil, taken instead of the liquid petrolatum, in similar doses will surely do the work. In addition, the patient should be weaned of the use of opiate by employment of another analgesic, if required, such as extract of hyoscyamus, 0.02 Gm., phenobarbital, 0.03 Gm., and amidopyrine, 0.3 Gm., in capsules, repeated every two to four hours as required. If this does not suffice to relieve the pain, codeine phosphate, 0.03 Gm., may have to be added for a time.

TUBERCULOSIS AS CONTRAINDICATION TO ATHLETICS

To the Editor:—I recently examined a boy, aged 15 years, who was referred to me by his father with particular reference as to whether to allow his son to participate in athletics. The boy is attending high school and is a member of the school soccer team. The boy's mother died of tuberculosis at the age of 26 when the boy was 4 years of age. In the mother's family all the brothers and sisters died of tuberculosis, also the mother's father. The boy was in actual contact with the tuberculous mother during four years. The boy is now 5 feet 9 inches (175 cm.) in height, weighs 127 pounds (57.6 Kg.), is of good build, and on detailed examination presents a normal chest. Roentgen examination reveals an angular symmetrical chest. There is calcification and prominence of both hili associated with a calcified focus in the second intercostal space on the right side. The diaphragm is smooth. The total heart area is proportionately small. The roentgenologist came to the conclusion that there was a healed tuberculous focus in the second intercostal space on the right side. There is, however, no evidence of any recent involvement. The question in this case arises as to whether to prohibit this boy, who is physically normal, from playing in a sport such as soccer, of which he is fond, or to allow him to continue to indulge in any such strenuous athletic activity. Is there a possibility of the healed tuberculous process "lighting up" at any time. Please omit name. M.D., New York.

Answer.—As it is impossible to tell absolutely from a roentgenologic examination whether the focus of tuberculosis has entirely healed, this boy must be watched from the standpoint of possibly having living tubercle bacilli present in the affected area. As he is underweight for his height and in his rapidly growing years, he should never exercise to the point of fatigue or exhaustion, such as is necessitated by competitive sports such as soccer. His exercise should consist of walking or calisthenics. Every effort should be made to prevent a lighting up of his old focus; especially should he avoid fatigue and exhaustion, spend plenty of time in the fresh air, eat plenty of good general diet containing adequate calcium (milk, eggs and vegetables) and vitamins, including cod liver oil. He should be built up if possible so that his weight more nearly corresponds with his height.

TREATMENT OF MAXILLARY SINUSITIS

To the Editor:—I have a patient who has had a chronic maxillary sinusitis for about ten years and is subject to frequent acute relapses. He has been to various specialists. He usually gets relief for a short time, but recently he has failed event to get temporary relief. Some blood is discharged from both nostrils and is presumably coming from the sinuses. He has had the sinus (the one causing most of the trouble) opened and irrigated and treated many times. Would you advise a more radical operation and curet the sinus or not?

R. H. Dunn, M.D., Rosholt, Wis.

Answer.—It is quite possible that erosion, either of the mucosa of the sinuses themselves or of the turbinates or septum, might be the cause of the appearance of blood. Whether a more radical operation should be done can be judged only by careful examination of the patient himself.

RECURRENT DERMATITIS NOT DUE TO MAGNESIUM SULPHATE

To the Editor:—Are there any cases on record in which the long continued taking of magnesium sulphate, say a dose every other night, has caused chronic eczema? I have been doing this for about five years to hold down high blood pressure, and for the last five months both hands are broken out with a bad case of chronic ezcema which has not been benefited by any kind of treatment. This breaking out might have been started by poison ivy early this spring as I have had it at various times for forty years; however, it has never been so persistent before. What would you suggest? Please omit name. M.D., Oklahoma.

Answer.—The magnesium sulphate probably has nothing to do with the production of the eczema described in this instance. It is probably of allergic nature and it is quite possible that the present recurrence of the dermatitis is due to ivy. Recurrent dermatitis of this type is very difficult to manage. General suggestions will be of no value. Specific things must be outlined and these can be determined only by the careful examination of a competent physician.

COLLOIDAL SILVER — CALCIUM LACTATE IN NEPHRITIS — ACID TREATMENT OF HAY-FEVER

To the Editor:—Please give me the following information: 1. Discuss the use of colloidal silver, such as choleval, given intravenously in cases of inflammation or stone in the gallbladder. 2. Discuss the efficacy of large doses of calcium lactate in nephritis with edema. 3. Discuss the value of nitrohydrochloric acid in the treatment of hay-fever.

F. R. Perfect, M.D., Lykens, Pa.

Answer.—1. Choleval is claimed to be a colloidal silver preparation with the use of bile acid salt as protective colloid. It is a brownish black water soluble powder, the intravenous use of which in doses of 10 cc. of a 1 per cent solution has been advocated in inflammatory processes of the biliary passages. Its value in this condition is not established, and it has not been admitted to New and Nonofficial Remedies.

2. Calcium lactate, even in large doses, is not an important remedy in edema. Calcium chloride in higher doses is no doubt more efficient but also more disagreeable.

3. Nitrohydrochloric acid seems to have been helpful in some cases of hay-fever and to have failed completely in others. Whether the favorable effect, when such was observed, was due to accidental association, to suggestion, or to mobilization of calcium as part effect of the tendency to acidification of the system is still undecided.

INTERSTITIAL KERATITIS

To the Editor:—A girl, aged 14, developed a bilateral interstitial keratitis two years ago and was treated at a hospital at that time for a couple of months. She has been under my care since July 1, and has been given bismuth salicylate intramuscularly and a potassium iodide mixture orally. A Wassermann test made during the latter part of August was 4+. Kindly outline a detailed treatment. Is arsphenamine contraindicated in cases with keratitis; if so, why? There are no other signs of congenital syphilis. Please omit name. M.D., Saskatchewan.

Answer.—Arsphenamine is not contraindicated in interstitial keratitis, nor is it of any especial benefit above any other accepted treatment for congenital syphilis. It is the generally accepted opinion that, after the first acute stage of interstitial keratitis has passed, the systemic treatment had best be confined to mercury and the iodides, by inunction or injection. The best results are obtained by the cooperation of the ophthalmologist and the syphilologist, the latter having experience with congenital syphilis that the former lacks.

TREATMENT OF HEMORRHAGE AFTER EXTRACTION OF TEETH

To the Editor:—A woman, aged 55, has six remaining teeth, which are definitely infected and are about to be extracted. She has always had a severe hemorrhage after previous extractions—the last one four years ago. She bled severely following three surgical operations which she has undergone. The coagulation time of her blood is twelve minutes. What should be done, first, to reduce the coagulation time, and, secondly, to treat the hemorrhage after extraction? Please omit name. M.D., Connecticut.

Answer.—The coagulation period in cases of this type is usually definitely lowered by the intravenous injection of 50 cc. of a 50 per cent dextrose solution, together with the intravenous injection of 1 Gm. of calcium chloride. This may be repeated three or four times on alternate days. When the coagulation time has been brought down to five or six, or even seven, minutes, the teeth may be removed, and at the time the gum tissue should be securely sutured.

IMPOTENCE AFTER JUVENILE EXCESS

To the Editor:—A white man, aged 28, indulged in sexual excesses for ten years, beginning at the age of 16. At 26 he became engaged and gave up "running around." He married, three months ago, and found himself unable adequately to complete the sexual act. During the past two years he has put on considerable fat, which seems, however, to be normally distributed. The pubic hair has been slowly falling out during the past year, although the general distribution of hair is normal. There is no venereal history, and the Wassermann reaction is negative. A specimen shows a rather small discharge which contains numerous actively motile spermatozoa. Treatment for several weeks with testicular extracts has brought only occasional temporary help—if this can be credited to the extracts. Please give prognosis and treatment. Please omit name and address. M.D., New York.

Answer.—Symptoms of sexual exhaustion following juvenile excesses are a rather frequent occurrence. The absence of any venereal history excludes the administration of any local or antisyphilitic treatment. Testicular extracts have been found to be without effect; occasionally improvement of the productive and cohabitative sexual power is observed after repeated hypodermic administration of an extract of the anterior lobe of the pituitary body.

Wyoming February and June Examinations

Dr. W. H. Hassed, secretary of the Board of Medical Examiners of Wyoming, reports the written examination held at Cheyenne, Feb. 3 and June 2, 1930. The examinations covered 12 subjects each. An average of 75 per cent was required to pass. Three candidates were examined and passed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
University of Colorado School of Medicine	(1929)	89.8
Hospital College of Medicine, Louisville	(1904)	75
Creighton University School of Medicine	(1910)	85.8

Dr. Hassed also reports 4 physicians licensed through reciprocity with other states and 1 by endorsement of credentials at the same meeting. The following colleges were represented:

College LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Chicago Homeopathic Medical College	(1902)	Nebraska
Creighton University School of Medicine	(1915)	Nebraska
Univ. of Nebraska Coll. of Med.	(1927) S. Dakota, (1929)	Nebraska

College ENDORSEMENT OF CREDENTIALS	Year Grad.	Endorsement with
Western Reserve University School of Medicine	(1894)	Dip. End.

Minnesota April Examination

Dr. E. J. Engberg, secretary of the Board of Medical Examiners of Minnesota, reports the oral, written and practical examination held at Minneapolis, April 15-17, 1930. The examination covered 12 subjects and included 60 questions. An average of 75 per cent was required to pass. Forty-two candidates were examined and passed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
University of Georgia Medical Department	(1928)	87.4
Northwestern University Medical School	(1928)	90.6, (1929) 89.5, 92.1, (1930) 92
Rush Medical College	(1930)	91.6
University of Maryland School of Medicine	(1928)	91.1
Harvard University Medical School	(1928)	91.2
University of Minnesota Medical School	(1929)	86.4,* 90.1,* 90.2,* 90.2,* 92.3,* 94.2, (1930) 85.4, 85.6, 86.3, 87.5, 89.2,* 89.5, 90.1,* 90.2,* 90.2, 90.4, 91.2, 91.3, 92, 92.3, 93.1,* 93.2, 93.4*
St. Louis University School of Medicine	(1929)	91.4
Creighton University School of Medicine	(1929)	87.5, 88.4
Eclectic Medical College of Ohio	(1926)	88.1
Ohio State University College of Med.	(1925) 88.2, (1928)	86
University of Pennsylvania School of Med.	(1927) 91.3, (1928)	89.5
University of Pittsburgh School of Medicine	(1928)	85.3
Medical College of the State of South Carolina	(1928)	92
University of Wisconsin Medical School	(1928)	94.6

Dr. Engberg also reports 5 physicians licensed through reciprocity with other states and 2 by the endorsement of National Board credentials. The following colleges were represented:

College LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
George Washington University Medical School	(1924)	Illinois
Creighton Univ. School of Med.		Nebraska
University of Virginia Departme		Virginia
University of Pittsburgh School		Penna.

College ENDORSEMENT OF CREDENTIALS	Year Grad.	Endorsement of
University of Michigan Medical School	(1928)	N. B. M. Ex.
University of Pennsylvania School of Medicine	(1925)	N. B. M. Ex.

* *This applicant has received an* M.B. degree and will receive an M.D. degree on completion of one year's internship in a hospital.

Book Notices

INFANT NUTRITION: A TEXTBOOK OF INFANT FEEDING FOR STUDENTS AND PRACTITIONERS OF MEDICINE. By William McKim Marriott, B.S., M.D., Professor of Pediatrics, Washington University School of Medicine. Cloth. Price, $5.50. Pp. 375, with 53 illustrations. St. Louis: C. V. Mosby Company, 1930.

Apparently the only serious unfavorable criticism that might be made of this new contribution to infant nutrition relates to the typography of the volume. The paper is not up to the quality of the material printed on it, the type column is too wide, and the size of the book is inconvenient. The book purports to be a summary of present-day knowledge concerning the nutritional requirements of infants under normal pathologic conditions. It therefore concerns itself with growth and development, the metabolism of various ingredients of food, vitamins, the study of the stool, breast feeding, artificial feeding, the various types of substances used in feeding, disturbances resulting from malnutrition and bad feeding, and nutritional disturbances from other causes. Special chapters are, of course, devoted to highly important topics such as rickets, tetany, scurvy, disturbance of the acid-alkali balance, and the nutrition and development of the teeth. The author's style is simple, direct and above all graphic, so that he gives accurate pictures of the conditions with which he is concerned, and explicit instructions when these are available. It is taken for granted that the book is written for the medical student and the practitioner, so that it is unnecessary for the author to expand his text unduly by needless definitions or explanations. As might be anticipated, Dr. Marriott makes available fully adequate discussions of the original contributions which he himself has made to the field of nutrition. His chapter on vitamins gives within a few pages practically all that it is essential for the practitioner to know in this field. His judgments are unusually sound and conservative. He makes clear the various methods of treating cow's milk for proper use in infant feeding. He speaks directly to the point regarding commercially prepared infant foods. In the brief period since it was first made available, this book has acquired an extraordinary popularity. Perhaps the publisher will find it possible in the preparation of future editions to provide a volume more nearly approaching modern knowledge of typography.

UMSTIMMUNG ALS BEHANDLUNGSWEG. Vortragsreihe, gehalten zu Wiesbaden veranstaltet vom Wiesbadener Ortsausschuss für das ärztliche Fortbildungswesen in Preussen (Vorsitz. Prof. Dr. Determann, Schriftf. Dr. Strakosch) vom 31. März bis 5. April 1930. Herausgegeben von Prof. Dr. Determann. Paper. Price, 16 marks. Pp. 262, with 34 illustrations. Leipzig: George Thieme, 1930.

This title, which literally means "change of tone or pitch as therapeutic method," might be more freely translated as "alterative therapy." The book is a symposium chiefly on "nonspecific cell activation" by numerous prominent German students of the subject, each of whom reports the degree to which these newer methods have been found helpful in his particular field. It is led by Wolfgang Weichardt, who takes a wide view of "Umstimmungs-therapy," including in it not only sensitization but also desensitization, used, for example, in allergic conditions. He shows by experimental muscle curves how minute amounts of protein destruction products as well as colloidal metals may markedly increase the activity of cells. He also shows that pathogenic micro-organisms may be activated in their growth by similar means. In infectious diseases, therefore, the problem of nonspecific immunization is to stimulate to the highest possible degree the defensive processes without activating the growth of the micro-organisms. Ferdinand Hoff brings out the regular biphasic character of these reactions: fever, leukocytosis and acidosis, followed by reduction of temperature and leukocytes and alkalosis, and that these are nothing more or less than centrally induced changes in the vegetative nervous system in the direction of sympatheticotonia during the first phase, and parasympatheticotonia during the second phase. Alfred Schittenhelm emphasizes the high degree to which success with this method depends on the individual reactivity of the patient; and Hermann Köninger, that not only the dose and its frequency of repetition but also most especially the time in the disease process when these methods are resorted to may determine success or failure. Then there follow chapters on the alterative value of the various therapeutic agencies, such as diet, mineral waters, hydrotherapy, electricity, radiation, climate, endocrines, proteins, lipoids, other medicines, and psychotherapy, in connection with some of which there is a tendency to interpret the term "umstimmung" perhaps somewhat too liberally. The rest of the book is taken up with the discussion of the application of this therapy to the diseases of the various organs and systems by recognized clinical specialists. Enough has perhaps been cited to show that this symposium affords one the privilege of brief but intimate contact with some of the latest therapeutic hypotheses agitating some of the foremost minds of the "land of thinkers."

Two Thousand Years of Science: The Wonders of Nature and Their Discoverers. By R. J. Harvey-Gibson, C.B.E., D.L., M.A. Cloth. Price, $4. Pp. 362, with 121 illustrations. New York: Macmillan Company, 1929.

In recent years there have been numerous efforts to popularize the various sciences and to convey to the lay reader the information possessed by specialists in various fields. There have been many interpretations of medical science but less often have works appeared on such fundamental subjects as astronomy, physics, geology and practical biology. Professor Gibson has endeavored to cover these fields, using a method of approach that is chronological and historical and writing with a feeling for public interest that is well nigh journalistic. Unfortunately, he finds it impossible to portray chemistry or biochemistry without numerous specimens of formulas and diagrams which can only confuse rather than aid the average reader.

Elementary Practical Biochemistry. By W. A. Osborne, Professor of Physiology, University of Melbourne, and W. J. Young, Associate Professor of Biochemistry, University of Melbourne. Third edition. Cloth. Price, 12/6. Pp. 154. Melbourne: W. Ramsay, 1930.

This elementary textbook is intended as a preclinical companion volume to Ivan Maxwell's "Clinical Biochemistry." Each "lesson" gives a brief "theoretical" discussion of the subject matter followed by the most elementary qualitative laboratory experiments, many of which are misleading because of the qualitative character of the work and the brevity of the theoretical presentation. The authors present a great array of facts and tests in 1, 2, 3 and a, b, c orders. Almost no experimental evidence is cited to support the theoretical conclusions given. The text is too elementary for the class A schools in the United States.

Personal and Community Health. By Clair Elsmere Turner, M.A., Dr.P.H., Professor of Biology and Public Health in the Massachusetts Institute of Technology. Third edition. Cloth. Price, $2.75. Pp. 443, with 62 illustrations. St. Louis: C. V. Mosby Company, 1930.

Turner's book is well known to teachers of hygiene in secondary schools and in colleges. Both personal and community health are discussed. The material on the former is sufficiently complete to serve as a basis for a college course, although the discussion of hygiene of reproduction, difficult at any time to present, would be more useful if some of the details had been omitted. The part of the book dealing with community health is, on the whole, excellent, particularly those chapters dealing with school hygiene, industrial hygiene and public health administration. In the discussion of immunity, Ehrlich's side-chain theory has been given in some detail. In view of the present tendency to get away from such a fantastic representation of physiologic processes, it would seem unnecessary to retain so much of the material. It is unfortunate that only d'Herelle's conception of the bacteriophage is given as certainly it is not accepted by all workers in this field. Another controversial point is in regard to the cause of the common cold. It seems to be true, however, that not all colds are infectious nor are they all contagious. Anaphylaxis is a difficult subject to present even to advanced students. Perhaps less space could have been given to this and more to the subject of phagocytosis. On the whole, however, the book is an excellent one to put into the hands of college and secondary school students.

Handbücherei für das Gesamte Krankenhauswesen. Herausgegeben von Adolf Gottstein. Band I: Krankenhausbau. Bearbeitet von R. Schachner, H. Schmieden und H. Winterstein. Band II: Fachkrankenhäuser. Bearbeitet von K. Biesalski, H. Eckhardt, W. Gottstein, S. Hammerschlag, W. Mobitz, H. Ulrici und K. Wickel. Paper, 26 marks and 16 marks. Pp. 344, with 244 illustrations and pp. 266, with 73 illustrations. Band III: Sondereinrichtungen im Krankenhaus. Bearbeitet von H. Braun, K. W. Clauberg, usw., usw. Paper, 25 marks. Pp. 396, with 55 illustrations. Band V: Technik im Krankenhaus. Bearbeitet von J. Diehl, F. Eckhardt, J. Fichti, E. Seligmann, W. von Sellin und F. H. Thies. Paper, 22.40 marks. Pp. 310, with 75 illustrations. Band VI: Ernahrung Diatküchen, Kostformen. Bearbeitet von L. Kuttner, K. Isaac-Krieger und D. Kwilecki. Paper, 10.40 marks. Pp. 143, with 11 illustrations. Berlin: Julius Springer, 1930.

The German medical profession has made available a system for practically every aspect of medical practice and now offers a systematic guide to the building and control of the hospital. This appears in six volumes. The first volume deals with the general hospital; the second with special hospitals; the third, with operating rooms, x-ray rooms, pathologic and serologic departments, medical and general libraries, and similar special features of all hospitals. The fourth volume has not yet been made available. The fifth volume concerns the organization and technic of hospital conduct, and the final volume deals with nutrition and dietetics. As might be expected, each of the contributors has done his utmost to cover his subject fully. For those workers in the hospital field who can read German, the volumes will be replete with a vast amount of valuable advice and suggestions.

The Devil: An Historical Critical and Medical Study. By Maurice Garcon and Jean Vinchon. Translated by Stephen Haden Guest from the sixth French edition. Cloth. Price, $3.50. Pp. 288. New York: E. P. Dutton & Company, Inc., 1930.

The idea that an evil demon of some sort might be concerned with human diseases and responsible for most troubles has existed since the beginning of man's life upon this earth. The French philosophers who contribute to this study show how the devil belief has been invariably linked with magic and mystery, and how modern psychologists have recognized the relationship of this belief to mental disturbances. Chapters on demoniacal madness and exorcism of devils conclude the work. Recognizing the great place played by the devil in many religious beliefs, the authors conclude with a recognition of a desirable combination of medical and religious efforts in freeing men from such beliefs.

Handbuch der pathogenen Mikroorganismen. Herausgegeben von W. Kolle, R. Kraus und P. Uhlenhuth. Band X, Lieferung 43: Methoden der Tumorforschung. Von Prof Dr O. Teutschlaender und Prof. Dr. R. Werner. Einrichtung von Instituten und Laboratorien. Von Prof. Dr. L Haendel Mobile bakteriologische Laboratorien. Von Prof. Dr. R Doerr. Third edition Paper. Price, 15 marks. Pp. 637-800, with 107 illustrations. Jena: Gustav Fischer, 1930.

Methods of investigation of tumors are here discussed by two well known Heidelberg workers. Their article includes much useful information and does not give disproportionate space to trivial and discredited items. The construction and equipment of bacteriologic laboratories, topics of perennial interest, are dealt with by Haendel clearly and broadly but, as natural, with a strong Teutonic slant. Mobile bacteriologic laboratories, so important in war times and for certain kinds of exploring expeditions and epidemiologic investigations, are treated adequately by Doerr.

Congenital Club-Foot (Talipes Equinovarus). By E. P. Brockman, M.Chir., F.R.C.S., Orthopædic Surgeon, Westminster Hospital. Cloth. Price, $4. Pp. 110, with 92 illustrations. New York: William Wood & Company, 1930.

Congenital clubfoot is a common condition. The causes and treatment are still under discussion. The author presents the various theories of etiology. He believes that the cause is a failure of development of the structures of the foot independent of any extrinsic influences. This results in subluxation of the astragalocalcaneoscaphoid joint and shortening of the muscles that control the socket for the head of the astragalus. He describes pathology, anatomy and various types of deformity. The treatment of various types and at different ages is discussed. The subject matter is well chosen and the sequence is excellent. The illustrations are well selected and executed. There is a disagreement with the author's position concerning early treatment. It is a book that should be read by every orthopedic surgeon and can be read by the obstetrician and general practitioner with benefit. This book was awarded the Robert Jones gold medal given by the British Orthopedic Association.

Ergebnisse der sportärztlichen Untersuchungen bei den IX. Olympischen Spielen in Amsterdam, 1928. Herausgegeben von F. J. J. Buytendijk. Paper. Price, 12 marks. Pp. 230, with 92 illustrations. Berlin: Julius Springer, 1929.

In this volume the author cumulates some of the information concerning the condition of the body and the health of the athlete arising from studies of the athletes in the Olympic games held in Amsterdam in 1928. In those games particular provisions were made for careful study of the athletes before and after various contests were undertaken and some significant facts were established concerning the effects of athletics on the heart, the blood pressure and the condition generally. Of particular importance was the fact that the hearts of athletes are not usually enlarged but indeed are found to be somewhat smaller immediately after participation in athletic efforts. The book is illustrated with innumerable diagrams and roentgenograms which bring out fully the facts that have been mentioned.

Prosthetic Dentistry: An Encyclopedia of Full and Partial Denture Prosthesis. By Ira Goodsell Nichols, D.D.S., Lieutenant Commander, DC—V(S), USNR, Special Lecturer and Instructor in Dental Prosthesis, Dental Department, United States Naval Medical School, Washington, D. C. With collaboration of forty-five authorities. Cloth. Price, $12.50. Pp. 687, with 833 illustrations. St. Louis: The C. V. Mosby Company, 1930.

This book cannot be properly classed as a treatise on prosthetic dentistry, as it refers only to dentures, omitting crown and bridge work, which is definitely a part of prosthetic dentistry. Nor should it be called an encyclopedia, but rather a collection of articles by a miscellaneous group of forty-five teachers, practitioners and commercial men, ranging from a few excellent teachers to a number who might be classed as unknowns. The chapter headings suggest an orderly plan, but there is so much diversity of opinion that one would soon be lost if he should undertake to use this as a practical guide. It is doubtful whether any single contributor would approve of a majority of the articles selected from the writings of the others. The reading of such a book leaves the dentist in much the same position as a dental student would be at the close of a course of lectures given by forty-five different men. Most of the illustrations are from previously published articles, or from dental supply house catalogues.

Clinical Bio-Chemistry. By Ivan Maxwell, M.D., B.S., M.Sc., Lecturer in Physiology and Clinical Bio-Chemistry, University of Melbourne. Second edition. Cloth. Price, $3.60. Pp. 269, with illustrations. Melbourne: W. Ramsay, 1930.

This work is intended primarily for the medical students at Melbourne University. It presents in a well organized fashion many of the qualitative and quantitative methods in vogue in clinical laboratories. Renal efficiency is well presented from the points of view of urine formation, nitrogen retention in blood, comparison of the blood chemistry and total excretion of urea, and lastly the renal elimination tests by phenolsulphonphthalein. Glycosuria and pancreatic efficiency tests are treated in separate chapters, but the quantitative methods for urinary dextrose are old and unreliable. However, a good titration method is recommended for the blood sugar estimations. Acidosis and alkalosis are treated in a clear and concise manner. Both qualitative and quantitative tests for determining hepatic efficiency are discussed in some detail. In no cases are the methods discussed critically as to reliability and rapidity. At the close of each chapter, a list of references to authorities is given.

Heredity in Man. By R. Ruggles Gates, Ph.D., LL.D., F.L.S., Professor of Botany in the University of London (King's College). Cloth. Price, $6. Pp. 385, with 87 illustrations. New York: Macmillan Company, 1929.

This volume is not a new work but a complete revision from a more modern point of view of the author's previous work on "Heredity and Eugenics." In his preface he points out that contributions to heredity by modern medical writers are more scientific than were those of the past and that therefore the scientific progress of the subject is more rapid. The present edition covers first the general aspects of the subject, then the inheritance of anatomic abnormalities, and then blood changes, metabolic defects, allergic disturbances, special defects, mental differences and racial crossings. There is a good reference bibliography and an index. The book is also intelligently illustrated. The reader who wishes a ready reference to current research will find it here. Many topics are considered too briefly for the advanced student. There is, furthermore, no concession to the ignorance of the general reader. The book will be useful to medical and other students as a guide.

Report of the International Conference on Goiter in Berne, August 24-26, 1927. Edited by the Swiss Goiter Commission. Paper. Pp. 537, with illustrations. Berne: Hans Huber, 1929.

The conference here reported was held in Berne, Aug. 24 to 26, 1927. The American translation became available late in 1929. Led by Professor Aschoff, experts from all over the world considered various special aspects of the goiter problem. Thus the leaders on pathologic anatomy were Aschoff, Wegelin and Marine, on pathologic physiology Plummer, Breitner and de Quervain, and on etiology and epidemiology Bérard, McCarrison, Galli-Valerio and Bircher. Finally the discussion on prophylaxis was opened by von Jauregg, Muggia and Silberschmidt. The participants included several hundred physicians representing all the great nations with approximately twenty-five from the United States. The report here reviewed was prepared by Drs. S. D. and Virginia C. Van Meter. As might have been anticipated, this conference ventilated every possible aspect of the subject and every reasonable point of view and reached no certain conclusion. Neither did it establish any point not previously established. It did serve to confirm the view that pathologic forms of goiter are more frequent where simple goiter is more frequent and that the prophylactic use of iodine lowers the incidence of simple goiter. The statistical data and the exhibits were exceptionally complete.

The Right Honourable Sir Thomas Clifford Allbutt, K.C.B., M.A., M.D., F.R.C.P., F.R.S., Hon. M.D., D.Sc., D.C.L., LL.D., Regius Professor of Physic in the University of Cambridge. A Memoir. By Sir Humphry Davy Rolleston, G.C.V.O., K.C.B., M.A., Regius Professor of Physic in the University of Cambridge. Cloth. Price, $6. Pp. 314, with 3 illustrations. New York: Macmillan Company, 1929.

The name of Allbutt is familiar to most of the medical profession of the world primarily because he practiced as a physician for more than half a century. He attained one of the leading positions in medical practice available in the world. He contributed notably to progress in medical science and he was equally known for his contributions to medical history and to medical literature. The consideration of his life by Sir Humphry Davy Rolleston is written *con amore*. Unfortunately the author has adopted a chronological approach to the subject rather than the form of consideration which deals with the various aspects of Sir Thomas Allbutt's work that have been mentioned. Thus, the biography is factual rather than critical. Among the particularly interesting accomplishments of the subject of this biography are the introduction of the clinical thermometer, the preparation of a system of medicine which achieved world recognition, the delivery of numerous philosophical addresses which served to define the trend in the development of medicine, investigations in the field of medical history leading to the publication of several books of permanent value, the publication of a book on medical writing, now in its third edition, which still commands respect and admiration, and, most of all, the setting of a standard of medical practice both as a general practitioner and as a consultant, which have served and which may well continue to serve as models through the centuries. The biography is excellently annotated, so that it becomes possible for any reader who cares to pursue any aspect of the subject to make references to any special phase of the subject that may attract him. Throughout the work appear the names of leaders of medicine in Great Britain, on the continent and in the United States with whom the life of Sir Clifford Allbutt came in contact. Unfortunately, his letters were few; but such as have been available and as are incorporated in his life have the interest that might be expected from their writer. Here is a biography which every physician interested in the history of our times will find exceedingly readable and informative.

Handbuch der inneren Sekretion: Eine umfassende Darstellung der Anatomie, Physiologie und Pathologie der endokrinen Drüsen. Herausgegeben von Dr. Max Hirsch. Band II, Lieferung 8: Entwicklung und Wachstum. Von Prof. Dr. F. Gudernatsch. Paper. Price, 27 marks. Pp. 1493-1744, with 59 illustrations. Leipzig: Curt Kabitzsch, 1930.

This is an excellent monograph on growth and development, with especial reference to the rôle of the endocrine glands in these processes. Years ago the authors did some good pioneering experimental work in this field, especially on the rôle of the thyroid and the thymus in growth. In this monograph the entire literature is covered in a thoroughly critical review. The list of references occupies forty-four pages. The gaps in our knowledge are indicated. At present the weakest link is the rôle of the thymus. The author calls the thymus a "growth gland." If this is so, it probably applies at least for mammals only in the early stages of interuterine life, when accurate experimental attacks on the problem are difficult. The monograph will be useful to internists, pediatricians and biologists.

Yourself, Inc.: The Story of the Human Body. By Adolph Elwyn, Department of Neurology, Columbia University. Cloth. Price, $3.50. Pp. 320, with 70 illustrations. New York: Brentano's, 1930.

This volume constitutes another attempt to give the public information in a simple form concerning the conception, the construction and the function of the human body. The book suffers, as do almost all such works, by the necessity for an extensive new vocabulary. The work is along the lines of an excellent series of articles now appearing in *Hygeia,* entitled "Simple Lessons in Human Anatomy." Because of its somewhat technical language and concentrated character, this book is better fitted for the experienced reader than for the average man.

Sexual Reform Congress, July 1-5, 1928, Copenhagen. Proceedings of the Second Congress of the World League for Sexual Reform. Editors: Dr. Hertha Riese, Frankford/Main, and Dr. J. H. Leunbach, Copenhagen. Paper. Price, 20.00 Rmk. Pp. 307. Copenhagen: Levin & Munksgaard, 1929.

The chief subjects of discussion at the second congress on sexual reform, held in Copenhagen in 1928, were the general subject itself, sexual pedagogy, birth control and legal aspects. Representatives of Russia discussed some of the remarkable experiments now being tried by the soviets. Much was said also of companionate marriage, free love and similar topics. Most of the papers are in German.

Applied Bacteriology for Nurses. By Charles Frederick Bolduan, M.D., Director, Bureau of Health Education, Department of Health, City of New York. Sixth edition. Cloth. Price, $2. Pp. 251, with 83 illustrations. Philadelphia: W. B. Saunders Company, 1930.

This edition differs only slightly from the fifth. Material on such subjects as undulant fever, Calmette's tuberculosis vaccine, tularemia and diphtheria toxoid has been brought down to date. Of the many books intended for use in the schools of nursing, this one is among the best. It is impossible to present the subject of bacteriology in so few pages adequately except by omitting many important things or by making extremely brief discussions. The latter is the method here followed.

Miscellany

MODERN TENDENCIES IN ANESTHESIA

In a recent article on requirements of substances used for basal anesthesia, Lendle[1] has discussed the modern tendencies in anesthesia. The attempt to improve gas anesthesia has led to a new method of dosage for nitrous oxide anesthesia. Experiments with other gases led to the use of acetylene and ethylene, but on account of their explosiveness these gases have not been adopted for general use. The renewed interest in rectal and intravenous methods of anesthesia was mainly due to the introduction of a new product, tribrom-ethanol, introduced as "Avertin," and of a barbital derivative of secondary butylbrompropenylbarbituric acid, introduced under the therapeutically suggestive name "Pernocton." Attempts to produce a surgical general anesthesia with these preparations proved unsatisfactory and so they were combined with inhalation anesthetics, especially with ether. Thus, the main object of this method, namely, to do away with inhalation masks, was defeated; however, the result was a new interest in the problem of combination anesthesia. In a combined anesthesia, the basal anesthetic is of primary significance. The definition of basal anesthesia as given by the author implies that it is more than merely preliminary to anesthesia, which formerly was usually attained by a morphine injection, in that it also is the main factor in the subsequent production of general anesthesia.

In the main part of the article, Lendle discusses first in general the requirements of a basal anesthetic, namely, the velocity of its action, its duration, the regulability or control and, finally, the breadth; that is, the difference between the anesthetic and the lethal dose. Then he gives his present opinion as to what extent avertin and pernocton fulfil or fail to fulfil these requirements. Avertin is, even following rectal administration, quickly absorbed, so that the anesthetic action reaches the maximum within several minutes. This he thinks is an advantage, but points out that the short duration of its anesthetic action is not desirable, because a basal anesthetic should produce an anesthesia of a reasonable duration and of an even depth. Regarding the control of avertin, the author states that the possibility of an indirect modification of the anesthetic action by restoratives, by glycuronic acid or by other substances has not proved satisfactory, either in the animal experiment or in the practical application. Because avertin is effective only for a short time, overdosage is necessary to obtain a sufficient duration of the anesthesia and thus the difference between the anesthetic and the lethal dose is very slight. In a combination anesthesia of avertin with ether, the anesthetic as well as the lethal actions of both components are merely additive. Mixtures in certain definite proportions show a slight reduction in the lethal action. However, it is not possible to increase the breadth of the anesthesia greatly by combination of avertin with other substances. This has been asserted wrongly by some investigators.

The author's final evaluation of avertin as a basal anesthetic is as follows: The short duration of the anesthesia and the overdosage that is necessary are proof that avertin does not meet the requirements of an agent for basal anesthesia; however, it is suited for use as an agent for preliminary anesthesia. It has not been proved as yet that by combining avertin with other substances an essential improvement in the breadth of the anesthesia can be obtained. In evaluating pernocton the author criticizes the slowness of its anesthetic action, and the extremely long duration. In order to improve the velocity and at the same time to decrease the duration, intravenous injection has been recommended. But if alkali has been added in order to improve the solubility, then there exists danger of thrombosis. As to the breadth of pernocton anesthesia, it has to be stated that there really is none. Animal experiments proved that absence of all reflexes cannot be produced with doses that are not already lethal, and in the light anesthetic action the breadth is likewise not very marked. However, because of the long duration of pernocton anesthesia, comparatively small doses may be given. A direct control is of course just as impossible in the case of pernocton as in avertin, and indirect control of

---

1. Lendle, L. Klin. Wchnschr. 9:1609 (Aug. 30) 1930.

pernocton by antagonistic analeptica is also ineffective. The author thinks that pernocton is even less suitable for basal anesthesia than avertin. Disadvantages are especially that total anesthesia cannot be effected with it, and that it gives rise to disgreeable complications and after-effects. However, because of the long duration of pernocton anesthesia, it may be suitable for lighter degrees of basal anesthesia.

Medicolegal

Evidence Admissible to Prove Criminal Abortion

(People v. Rongetti (Ill.), 170 N. E. 14)

Amante Rongetti was convicted of manslaughter on the basis of evidence tending to show that he had committed a criminal abortion. He appealed to the Supreme Court of Illinois. A coroner's physician testified that he made an autopsy on the body of the deceased and that he found a triangular punctured wound, about the size of the body of a fountain pen, on "the posterior fundus of the uterus," which was practically healed. In his opinion, death was caused by septic peritonitis due to an abortion, and the abortion was not necessary to preserve the life of the deceased. An embalmer testified that in embalming the body he made the puncture with his trocar. Rongetti testified on his own behalf, denying that he punctured the uterus, or that he performed any operation on the deceased, or that he did anything that could cause her to abort. His testimony was corroborated by the head nurse of the hospital. There was evidence tending to show that abortion might have resulted from violence to which the deceased was subjected prior to her admission to the hospital or from natural causes.

In the course of the trial, evidence was introduced to show that Rongetti had performed similar operations. The admission of such evidence, Rongetti claimed on appeal, was error. But, said the Supreme Court, where the intent with which an alleged offense was committed is a material element of the charge, and such intent becomes an issue on the trial, proof of former similar offenses, within reasonable limits, is admissible as tending to throw light on the intention of the accused in doing the act charged, and such evidence is competent in cases of this character. Such evidence, however, to be competent as proof of guilty knowledge, must show that the alleged similar offenses were in fact criminal offenses. Evidence of similar offenses is not admissible to prove that the defendant committed the act charged; it is to be considered only in determining the intent with which the act was done, when the jury is satisfied by other testimony that the defendant committed the act. The trial court erred, said the Supreme Court, in denying the motion of Rongetti to strike out the answer of a witness who testified that she had seen similar operations, and in allowing her to testify to her conclusion and to make general comparisons. She should have been required to testify as to the details of each of the operations to which she referred, so that the court might be able to judge as to whether or not such operations were criminal and tended to show a guilty intent in doing the act charged by the indictment.

Two physicians, testifying as experts, in answer to a hypothetical question gave it as their opinions that the hypothetical person described in the question came to her death as the result of an abortion and that such abortion was not necessary to preserve her life. Rongetti claimed that the opinions as given were incompetent and inadmissible and that these witnesses were allowed by the court to invade the province of the jury and to determine questions which the jury itself was impaneled to decide. The Supreme Court quoted with approval the principles laid down by it in *Fellows-Kimbrough* v. *Chicago City Railway Co.,* 272 Ill. 71, 111 N. E. 499, 502, as follows:

> Where there is a conflict in the evidence, as in this case, as to whether or not the party suing was injured in the manner charged, it is not competent for witnesses, even though testifying as experts, to give their opinions on the very fact the jury is to determine. Whether or not the collision or accident in this case caused traumatic neurasthenia, in the defendant in error, or caused the tumor in her breast, are ultimate facts upon which the jury must make their findings. It is no more proper, legally, for physicians to settle those questions for the jury by their direct answers than it would be for a motorman of another street car company to settle the question of negligence by testifying in broad terms that the plaintiff in error was guilty of negligence because its motorman failed to cut off the power by use of the canopy switch in time to prevent the collision. The rule in such cases is not different where hypothetical questions are put to the expert witnesses. A physician may be asked whether the facts stated in a hypothetical question are sufficient, from a medical or surgical point of view, to cause and bring about a certain condition or malady, or he may be asked whether or not a given condition or malady of a person may or could result from and be caused by the facts stated in the hypothetical question; but he should not be asked whether or not such facts did cause and bring about such condition or malady. [Citations omitted.] In cases where there is no dispute as to the manner and cause of the injury, and no dispute that there was an injury sustained by reason of the acts of which complaint is made, this court has held that a physician may then directly testify that a later malady was or was not caused by the accident or original injury, upon the same principle that he may testify that death resulted from a certain wound. [Citations omitted.]

The rule stated has never been departed from in any case in which the question was raised. The trial court in the present case was therefore in error, said the Supreme Court, in allowing the witnesses to invade the province of the jury and to testify as to ultimate facts which were for the jury to determine in this case, because there was a conflict in the evidence as to whether or not the deceased was injured in the manner charged and there was a dispute as to the manner and cause of the injury to deceased, if any, and also a dispute as to whether or not there was an injury sustained by her by reason of the acts of Rongetti of which complaint was made.

For the reason stated and others, the case was reversed and remanded.[1]

Insurance. Accident: Gonorrheal Ophthalmia.—The plaintiff suffered the loss of the sight of an eye, which became infected as a result of wiping his face on a towel on which there were gonococci or other germs He brought suit on an insurance policy that insured against injuries "effected solely through external, violent, and accidental means," and a verdict and judgment were rendered in his favor On appeal, the judgment was reversed. There is nothing in the evidence, said the Court of Appeals of Georgia, to indicate that the injury complained of was effected solely from external, violent and accidental means within the meaning of the policy sued on. The evidence does not indicate that the use of the towel effected any violent, external injury to the eye, nor that the eye had already been thus injured so as to expose it to infection from the ordinary use of the towel. Since all germ diseases, whether contagious or infectious, are contracted by taking within the body the disease organisms, an insurer might be liable for the contracting of any such diseases, whether through the mouth, nose, eye, throat or lungs, by reason of any ordinary exposure, were it not for the provision in the accident policy, which distinguishes it from a health policy, that the company is liable only for accidental injuries effected solely through external, violent means. So far as the case made out by the plaintiff showed, the gonococci became lodged and developed in the natural, normal tissues of the body, without being *in any* wise effected through external violent injury. Consequently, there could be no recovery on the policy sued on.—*Prudential Ins. Co. of America v. Herndon (Ga.), 151 S. E. 399.*

COMING MEETINGS

American Academy of Physical Therapy, Boston, November 12-14. Dr. Thomas L. Smyth, 111 North Eighth Street, Allentown, Pa., Secretary.
American Society of Tropical Medicine, Cleveland, December 27-30. Dr. Edwin Peterson, U. S. Naval Hospital, Washington, D. C., Secretary.
American Student Health Association, New York City, December 29-30. Dr. D. F. Smiley, Cornell University, Ithaca, N. Y., Secretary.
Radiological Society of North America, Los Angeles, December 1-5. Dr. I. S. Trostler, 25 East Washington Street, Chicago, Secretary.
Society of American Bacteriologists, Boston, December 29-31. Dr. James M. Sherman, Cornell University, Ithaca, New York, Secretary.
Southern Medical Association, Louisville, Ky., November 11-14. Mr. C. P. Loranz, Empire Building, Birmingham, Ala., Secretary.
Southern Surgical Association, Lexington, Ky., December 9-12. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.
Western Surgical Association, Kansas City, Mo., December 5-6. Dr. Frank R. Teachenor, 306 E. Twelfth St., Kansas City, Mo., Secretary.

---

[1] This case is again before the Supreme Court of Illinois, Rongetti having appealed from another conviction of manslaughter.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Puerperal Infection Due to Anaerobic Streptococci.—Brown asserts that puerperal infections due to ordinary pathogenic organisms in most instances are introduced infections, and infections due to anaerobic streptococci are usually endogenous. In the well organized obstetric clinic, the problem of anaerobic streptococcal infection should be a greater one than infection due to the hemolytic streptococci and other pathogenic organisms. Good technic can practically eliminate hemolytic streptococcal infections, with some exceptions, as the recent epidemic at the Sloane Hospital for Women in New York City indicates. In the present state of knowledge, anaerobic streptococcal puerperal infections will perhaps be best reduced by using some antiseptic preparation in the vagina at the beginning of and during labor.

Local Anesthesia in Gynecologic Operations.—Falls asserts that nearly every gynecologic operation can be done under local anesthesia reinforced by scopolamine and morphine. It is not the anesthesia of choice in uncomplicated cases. It is the method of choice in certain carefully selected complicated cases. The operator must be prepared to spend more time and patience in this type of operating, and deftness and gentleness in handling tissues are of paramount importance. Major abdominal operative procedures should not be attempted by the unskilled surgeon, since complications may occur that will try the skill of an experienced surgeon. Facilities for switching to general anesthesia should be available as well as the assistance of a trained anesthetist who cooperates in the management. A combination of nerve block and local infiltration is advisable in most of the work, especially the abdominal work. Premedication with scopolamine and morphine is a valuable adjunct.

Irregularities of Fetal Heart.—Study made by Hyman of the fetal heart sounds by means of the phonocardiogram has demonstrated that the occurrence of cardiac irregularities in uterine life is not an infrequent discovery. These irregularities can be divided into three general groups, the first two of which constitute about 80 per cent of all the irregularities. The first group consists of an exaggerated physiologic disturbance of the pacemaker mechanism in which a marked sinus arrhythmia develops; this condition persists throughout childhood and finally disappears at the latter end of adolescence. It has no especial clinical significance but it should be recognized in order to make an accurate differential diagnosis from the third and more serious group of irregularities. The second group of fetal arrhythmias consists of a skipping or alteration in the regular rhythm of the heart; this intermission is probably due to an intra-uterine extrasystolic arrhythmia. The general impression seems to be that the condition is relatively unimportant, as it disappears within a few days after delivery. Hyman believes that its occurrence is evidence of a hyperirritable myocardium which may be the result of improper hygiene, poor posture, or an unsuitable dietary on the part of the mother. This type of irregularity is not difficult to discover if present, and, like the first group of irregularities, it must be differentiated from the third type. The importance of the fetal irregularities lies primarily in the further investigation of the grossly perverted types of fetal heart rhythms seen in the third group. The combined attention of both obstetrician and cardiologist must be focused on the mechanism responsible for this change in the cardiovascular system of the fetus. If this condition is due to auricular fibrillation, as is suggested by graphic studies of this disease when compared to adult types of auricular fibrillation, indications as to therapy may be made and a new avenue of approach to the possible prevention of certain types of abortion may be accomplished.

Spirochetes in Puerperal Fever.—A mixed infection of spirochetes and pyogenic organisms has been observed by Lash during the puerperium. These spirochetes are different from the Vincent's or pallida forms. The spirochetal and pyogenic puerperal fever follows a characteristic pathologic and clinical course. The diagnosis is based on the character of the lochia and on the presence of spirochetes. The therapy used in this type of infection may be considered of nonspecific and probable specific nature. The importance of studying smears and the bacteriology of the lochia in puerperal infections is illustrated. It is only by such means that definite diagnosis, prognosis and therapy may be established in the study of puerperal fever.

Ectopic Pregnancy.—Urdan has analyzed 474 cases. Previous sterility does not seem to be an important factor, as only 10 per cent fall into the group classed as primary sterility. Pelvic infection is an important etiologic factor whether an inflammatory, postabortal or postpartum infection. The two most common symptoms are pain and bleeding. When coupled with shoulder pain and fainting, the diagnosis is almost absolute. Amenorrhea of five to six weeks followed by bleeding and pain is most common, but a good number of patients had a prolonged period of bleeding with the onset of the period, while many began to bleed from one to three weeks after a normal period. The amount of bleeding is less than in threatened abortion, the blood is darker, and generally it does not clot. External hemorrhage may be a manifestation of the death of the ovum and occurs when the uterus is beginning to cast off the decidua. Curettings showing only decidua may be pathognomonic of extra-uterine gestation. The temperature shows a moderate elevation, rarely above 101 F., and the pulse rate is proportionately increased, the average being from 90 to 110. The leukocyte count is of little value, though a high count does not indicate infection when this is present after severe intra-abdominal hemorrhage The diagnosis, except in cases with severe hemorrhage, is difficult. In this series only 58 per cent were correctly diagnosed. Any change in the rhythm of the menstrual flow with bleeding and abdominal pain must make one suspect extra-uterine gestation. The sedimentation time of thirty minutes or over favors extra-uterine pregnancy rather than inflammatory adnexal disease. The Aschheim-Zondek test should prove of value in differentiating adnexal disease from extra-uterine pregnancy. Posterior colpotomy should be resorted to in differentiating pelvic abscess from hematocele. Once the diagnosis is made, operation should be immediate except in those cases in which hemorrhage has not been profuse and the patient's general physical condition (for example, cardiac status) could be benefited by appropriate preoperative treatment. Blood transfusion, if necessary, should be done and in borderline cases should be performed to shorten the convalescence and aid in restoring the patient more rapidly to her normal status. In this series tubal ruptures were almost as frequent as tubal abortions, 40.50 per cent tubal ruptures and 48.31 per cent tubal abortions. There were fourteen deaths, or a mortality rate of 2.95 per cent. Five deaths were due to the anemia and shock attendant on severe hemorrhages; two were due to secondary hemorrhage, one to eventration, two to intestinal obstruction, and four to pulmonary complications. Three of the deaths due to primary hemorrhage and one of the deaths due to secondary hemorrhage occurred before the period when blood transfusion, as a therapeutic agent, was available.

Vital Capacity in Last Month of Pregnancy and Puerperium.—Vital capacity observations were made by Alward on sixty pregnant women. In the majority of cases there was normally a gradual reduction in the vital capacity in the last month of pregnancy. This is especially noticeable during the two weeks period before delivery. Following delivery there is a fairly sharp reduction in the vital capacity with a gradual return to normal limits, which is reached by the tenth day of the puerperium and remains so throughout the following days of the puerperium.

Gastric Juice in Pregnancy.—Arzt emphasizes that free hydrochloric acid and total acid of the stomach contents are lower in pregnancy than in the nonpregnant and that this deficiency is more marked early, at the time nausea and vomiting are most common. This absence of free acid is due to the fact that it is neutralized most likely by a regurgitation of the alkaline duodenal contents into the stomach. Caffeine citrate in these cases has a marked ability to cause an increased secretion of hydrochloric acid.

Contracted Pelves and Disproportion.—Four hundred and seventy-one cases of contracted pelves or disproportion between the pelvic canal and the child are presented by McGoogan and the method of delivery analyzed, 220 patients delivering spontaneously and 251 requiring operative intervention. The maternal mortality for the group is 0.42 per cent, both deaths being due to streptococcic septicemia. The fetal mortality for the group is 10.8 per cent, of which one third were due to intracranial hemorrhage. Surgical induction of premature labor gives results that are not inferior to other methods of delivery, the fetal mortality being lower, but the maternal mortality, owing to the risk of infection, greater. In 104 cases of cesarean section there was no mother lost and the fetal mortality was only 2.8 per cent. Craniotomy is the method of choice in those patients in whom the child has died in utero or in whom such a severe grade of infection is present that cesarean section is contraindicated.

*Healing of Tuberculosis. F. M. Pottenger, Monrovia, Calif.—p. 281.

Effect of Arteriosclerosis on Heart and Systemic Circulation.—Fahr and Davis made experiments which they feel prove that increased rigidity of the arterial system without changes in the diameter of the system causes no increase in the work of the left ventricle in expelling blood into and along the more rigid arterial system. In other words, arteriosclerosis not associated with increased blood pressure causes no increase in the work of the left ventricle. These experiments also prove that the volume flow of blood in a more rigid arterial system is as great as in a less rigid system. In other words, arteriosclerosis not associated with narrowing of the lumen of the arterial system is not detrimental to the volume flow of blood. It is possible that severe generalized arteriosclerosis may lead to a reduction in volume flow through the coronary arteries and thus aid in bringing on circulatory failure when the coronary arteries are already narrowed from severe coronary arteriosclerosis.

Newer Aspects in Problem of Essential Hypertension.—Keith and Kernohan feel that it behooves clinicians always to consider the diagnosis of a case of hypertension from the standpoint of the fundamental pathologic change. There are certain rare anatomic changes in the vascular system which give rise to hypertension, such as arteriovenous aneurysm and congenital stenosis of the isthmus of the aorta. In addition to the kidney they must think of other organs in the body as possibly being associated with the cause of hypertension. For instance, they must think of the thyroid gland and of the suprarenal gland together with tumors in the region of the latter. Also, they must think of the sympathetic nervous system, for vasoconstriction sometimes occurs in early cases of hypertension. Cases have actually been seen in which the condition has begun with vasoconstriction and in which, later, arteriolar thickening has appeared. Finally they must seek substances that will be effective in prevention of this vasoconstriction, or in its treatment when once it has developed.

Retinal Vascular Changes in Hypertension.—Wagener believes that it must be admitted that arterial constriction or spasm is the most dangerous element of hypertensive disease, that it may be the primary factor that results in arteriosclerosis, and that it is largely responsible, if not for the hypertension itself, at least for the retinal, cerebral and renal complications. It would seem that efforts should be directed especially to the discovery of the cause and to the relief of this tendency to arterial or, rather, to arteriolar constriction.

Causes of Hypertension.—The physiologic mechanisms concerned with the regulation of blood pressure in health and in disease are discussed by Bell and Pedersen; viz., the heart, the arteries and the arterioles, the capillaries, the vasomotor center, the vasomotor nerves, the depressor nerves, and the suprarenals. Hypertension has been produced experimentally in animals by pressor substances, increased intracranial pressure, removal of the depressor nerves, urinary obstruction, roentgen atrophy of the kidneys, and stenosis of the renal vein. Secondary hypertension of acute type occurs in man from physical exertion, sensory stimuli, increased intracranial pressure, and suprarenal tumors. Secondary hypertension of acute or chronic type occurs with glomerulonephritis, nephrosis of eclampsia, mercuric chloride nephrosis, polycystic kidneys, urinary obstruction, advanced amyloid disease, and degeneration of small renal arteries and arterioles. Secondary hypertension of chronic type is seldom seen except in association with renal disease. Obstruction in the renal circulation or obstruction of the outflow of urine seems to cause hypertension, probably through a reflex mechanism. Renal insufficiency alone does not cause a rise in blood pressure. Acute fulminating hypertension is probably a primary renal disease. Primary hypertension has its basis in inheritance. The defect inherited is an inferior vascular system which either reacts excessively to ordinary environmental stimuli or degenerates from inherent weakness.

Psittacosis.—Three cases of psittacosis are described by MacLachlan et al. clinically with necropsy observations in one case. The clinical picture may be one of atypical pneumonia or of a typhoidal state. The mortality occurs in the former, especially in older persons. The pneumonia is of the bronchial type, with collapse of lung, and the exudate is chiefly of phagocytic mononuclear cells. The most distinctive feature in the pneumonia is an hypertrophy and hyperplasia of the epithelial cells lining the alveoli. However, these cells do not enter into the formation of the exudate. The most recent work would indicate that psittacosis is caused by a filtrable virus. At present a diagnosis of psittacosis cannot be made without establishing contact, direct or indirect, with a parrot or other tropical bird.

Healing of Tuberculosis.—Pottenger concludes that tuberculosis heals as a result of the patient's immunity reaction. The efficiency of the immunity reaction is increased by repeated reinoculations. The effects of immunity are shown in the following services rendered to the host: (*a*) destruction of bacilli; (*b*) retardation of the passage of bacilli through the tissues; (*c*) elimination of bacilli through natural channels by caseation and cavity formation; (*d*) development of a state of desensitization to bacillary and nonbacillary toxins; (*e*) encapsulation or rendering inactive viable bacilli, which remain in the tissues; (*f*) ridding the body of the inflammatory products that accompany the infection, and (*g*) repair of the injury inflicted on the body by the disease. Treatment is efficacious to the extent that it is able to limit reinoculations of bacilli and bacillary protein to a minimum and create within the patient a resistance capable of coping with them as they occur.

Car Sickness.—Though car sickness is based on labyrinthine irritation, it is nevertheless true, Lebensohn believes, that errors of refraction and of muscle balance predispose a person to this malady. Hence persons so affected have probably a lowered threshold for nausea, and a digestive tract especially susceptible to further depressing influences. With the advent of smoother roads and easier riding cars and automobiles, car sickness is becoming less common. Susceptible persons will be less affected if they maintain a proper gastro-intestinal tone. Errors of refraction and muscle imbalance should be corrected. It is best not to go hungry when traveling, as the empty stomach is particularly sensitive to depressing influences. In severe cases, it may be necessary to allay the psychic tension with sedatives, while, to counteract the pylorospasm that precedes the retroperistalsis, the use of atropine is indicated. The value of sodium nitrite in seasickness has not been confirmed by British investigators.

Perforation of Larynx from Tuberculous Laryngitis.—Seven cases of perforation of the larynx by the tuberculous process reported from 1836 to 1899 are reviewed by Tyson. Six cases reported in the same period, in which perforation of the larynx took place by a process that was probably tuberculous, but in which the evidence was not sufficiently conclusive to warrant a definite statement, are also reviewed. One case of definite tuberculous perforation of the larynx is reported. The latter is the only case reported since 1899, and the probable explanations of this are pointed out. The diagnostic points in tuberculous perforation of the larynx are discussed and are correlated with the pathologic observations.

Dentigerous Cyst of Antrum of Highmore.—The unilocular cyst seen by Harris and Weidlein completely filled the antrum, and, despite its great size, had formed no fistulous tract into either mouth or nose. There were, however, two large bony dehiscences. It contained a poorly developed supernumerary molar, indicating that the cyst had taken its origin from an aberrant tooth bud or so-called follicle. The cyst bore no direct relation to the left canine tooth, which was unerupted and missing from the arch. This tooth, anchored by a shelf of bone, lay wholly outside the cyst. This cyst was of exceptionally long growth, as evidenced by its size and the impacted canine, which normally erupts between the tenth and thirteenth years of life. It may be concluded, therefore, that the shelf of bone that anchored the tooth so securely was gradually driven into the side of its root by the slowly forming cyst over a long period of years.

Blood in Various Anginas.—Shea asserts that the toxins of the various anginas may stimulate or paralyze the hematopoietic system. He reports six cases.

Patch Test in Contact Dermatitis.—The results of various methods of testing ninety-eight patients suffering from "contact dermatitis" are demonstrated by Ramirez and Eller. The patch method of testing was superior to other methods in determining sensitization to contact excitants, and particularly those of nonprotein nature.

Vital Capacity in Bronchial Asthma.—A study of the vital capacity in eighty-eight cases of bronchial asthma under varying conditions was made by Feinberg. There was a diminution in the capacity during the attack proportional to the severity of the latter. The average vital capacity between attacks was considerably decreased in adults but little altered in children. This may be interpreted as a greater tendency to complications in adults. Although the nature of this tendency has not been definitely ascertained, it is thought that emphysema is the most likely possibility. The presence of a chronic cough diminished the vital capacity still further. These and other observations seem to indicate that vital capacity determinations may be employed to great advantage in bronchial asthma to determine the progress and prognosis due to complications. This study also shows that bronchial asthma is frequently capable of producing permanent and organic changes, especially in adults, sufficiently marked to be discernible by vital capacity tests. It is suggested that bronchial asthma with its resultant complications is a disabling ailment more frequently than is ordinarily assumed.

Disappearance of Circulating Ragweed Pollen After Absorption from Nose and Throat.—By means of a modification of the Prausnitz Küstner reaction, an attempt was made by Cohen et al. to measure the disappearance time of circulating ragweed pollen material after absorption from the nose and throat. In eight out of ten nonallergic subjects the allergen could be demonstrated to be present for twenty-four hours. In no case was there any demonstrable at the end of forty-eight hours.

Food Allergy and Pollen Hay-Fever.—Rowe insists that the allergist must study the patient complaining of seasonal hay-fever from the point of view of sensitizations to other than pollen allergens. Such patients often have food sensitizations that are productive of gastro-intestinal symptoms, headaches, urticaria, eczema, asthma, and nasal congestion as well as other symptoms due to food allergy. The control of such food allergies is facilitated by the use of the elimination method of diet trial.

Allergy Due to Silk.—It is suggested by Taub that the problem of sensitization in eczema due to contact with silk and other proteins be given more attention in the examination of the patient. The results of a questionnaire sent out to a number of allergists indicate that this sensitization is more common than ordinarily considered.

Carbohydrate Metabolism Following Guanidine Deglycogenation. F. Bischoff and M. L. Long, Santa Barbara, Calif.—p. 201.

Response of Monkey to Withdrawal of Vitamin A from Diet.—Observations are reported by Tilden and Miller on eleven monkeys kept until death on a ration containing only 6 to 12 units of vitamin A daily, and on six monkeys maintained on a similar ration, except that it contained from 250 to 700 units of the vitamin per diem. The rations were exactly similar, except that in the case of the deficient ration the butter fat used had been aerated for eight hours at 120 C. and contained too little vitamin A to be detected by quantitative tests in rats. The first symptom of illness noted in the monkeys receiving the low vitamin A ration was loss of weight, which was followed sooner or later by loss of appetite and finally by colitis and death. In one animal, extensive edema was present shortly before death. There was no xerophthalmia, sinusitis or mastoiditis, and tongue abscesses were not found in any of the animals. Histologic study of the tissues of the monkeys showed keratinization of epithelial tissue in one or more sites in nine of the eleven animals. In a few instances the cornification was extreme, but in no instance were the conjunctivae involved in the keratinizing process. Six monkeys on the control ration, with one exception, remained well and gained weight. One animal developed a nonfatal dysentery, from which it appeared to have recovered when killed. The intestine showed no gross changes at necropsy, but microscopic examination revealed parasites in the intestinal wall. These parasites were not detected in the intestines of the animals on the deficient ration which succumbed to colitis.

Nickel Dissolved from Container During Pasteurization.—Pratt's study does not indicate that nickel dissolved from the container during pasteurization catalyzes the destruction of vitamins A, B or C during the pasteurization process.

Effect of Long Continued Parathyroid Administration.—Day asserts that the long continued administration of parathyroid extract to normal growing albino rats receiving a normal diet had no measurable effect on the percentages of body calcium and phosphorus in the animals.

Meningococcus Meningitis in Detroit in 1928-1930.—During the 1928-1929 meningitis epidemic in Detroit, sixty-two meningococcus strains were isolated by Norton and Broom from patients and thirty-three meningococcus strains from carriers (home contacts of the patients). These ninety-five strains were all agglutinated by a polyvalent antimeningococcus serum in a dilution of 1:400.

Seasonal Variations in Intestinal Flora.—A study made by Goldwasser and Kligler of the intestinal flora of a group of normal individuals over a period of twenty months revealed the fact that at certain seasons quantitative as well as qualitative changes occur. During the winter a condition of equilibrium exists, the number of bacteria is relatively high, the moisture content is low, and cocci and anaerobic spore formers predominate. In the spring (about April or May) there is a transformation: the total number of bacteria falls, the coli preponderate and cocci and anaerobic spore formers diminish. The curve of the coli-cocci ratio follows closely that of bacillary dysentery, suggesting some relation to the same primary favorable factor, the change in the intestinal environment favoring the development of this group of bacteria.

Typhoid Apparently Spread by Boiled Lobster.—The outbreak reported on by Anderson and Scamman is noteworthy in that the disease was spread by a food not previously incriminated, that unrelated persons in four different towns were involved, and that the contamination of the food occurred indirectly from the handling of associated material that was contaminated.

Tuberculosis of Hip Joint. D. S. O'Connor, New Haven, Conn.—p. 636.

Comparing Breast-Fed and Bottle-Fed Infants.—Glazier's study, though dealing with a limited number of infants, would suggest that infant mortality and frequency of infection have a definite relationship to poor economic and hygienic conditions. In group studies, "breast" or "bottle" feeding alone is not the determining factor in frequency of infection and infant mortality. The determining factors are hygienic and economic conditions. Infants in a district with poor economic and hygienic conditions have more frequency of infections, deficiency diseases, and a greater infant mortality, irrespective of breast or bottle feeding. In districts where economic and hygienic conditions are fairly good, the average bottle-fed infant does as well as the average breast-fed infant. Clinic infants have a mortality of one-half that of nonclinic infants in the same district.

Nutrition Clinic in Santa Ana Elementary School, Manila. A. Tupas, D. Belmonte and C. Cabrera.—p. 333.

Typhoid in Pregnancy.—Sixty-four patients, consisting of pregnant and puerperal women affected with typhoid, were studied by Villarama and Galang. Typhoid terminated pregnancy in about 78 per cent of their cases. The termination of pregnancy did not in any way cut short the course of the disease. Fetal mortality was 60 per cent of the fetuses born. Maternal mortality was about 26 per cent, more deaths having occurred among patients affected during the puerperium than among those affected during pregnancy. Of the three patients with positive blood culture for *Bacillus typhosus*, two recovered and one died. All the patients who had previously been inoculated with antityphoid vaccine recovered.

Confirmatory Sign of Free Fluid in Pleural Space.—Lasersohn says that dulness and decrease in the intensity of the breath sounds along the lateral chest wall and high in the axilla of the affected side is a confirmatory sign of free fluid in the pleural sac. Dulness with an increase in the intensity of the breath sounds in the axilla on the side that otherwise shows the classic signs of free fluid does not confirm this diagnosis, and is usually indicative of consolidation rather than of fluid. The sign is of value in the differential diagnosis of free fluid and the conditions with which it may be confused. The amount of fluid present is roughly proportional to the extent and degree of dulness and of decrease in the intensity of the breath sounds in the axilla. The high level in the axilla of free fluid due to capillarity and the compressibility of the lung periphery forms the basis for the signs of fluid in the axilla.

Two Cases of Connective Tissue Nevus. J. H. T. Davies.—p. 208.

Etiology of Juvenile Rheumatism.—Hill believes that acute rheumatism can be prevented, or at least its incidence considerably reduced, by children living a healthy life on a simple mixed diet, rich in milk, fruit and animal fats, and being exposed, lightly clad, to sunlight and the open air.

Value of Streptococcus Antitoxic Serum in Scarlet Fever.—The treatment of scarlet fever by means of scarlatinal streptococcus antitoxic serum proved so effective in the experience of Toyoda et al. as to reduce the death rate by half. The serum was found to have a particularly remarkable effect on the symptoms that are due to streptococcus toxin; viz., rash, fever, itching, vomiting, convulsions and palpitation of the heart. While the serum seemed to have some effect in reducing the incidence of complications, it did not appear to have any effect on complications that had already developed.

Removal of Safety Pin from Duodenum. J. E. Schofield.—p. 471.
*Passage of Gallstones Through Abdominal Wall. A. A. Davis.—p. 471.

Place of Pasteurization in Scheme of Milk Distribution.—The systematic pasteurization of ordinary market milk intended for consumption in large urban areas is, in MacGregor's opinion, unavoidable under present conditions where milk is collected and mixed from widely scattered and varied sources, not under such scrupulous control as to eliminate the risk of chance infections—a danger that experience shows to be real. Efficient pasteurization is of real protective value against bovine tuberculosis, and this practice could not be dispensed with until tuberculosis in dairy herds has been reduced to a minimum.

Radium in Gynecology.—The total number of patients treated by radium by Forsdike was 181. In the inoperable cases the results were: palliation and prolongation of life, 134, with none cured; borderline cases, 33, with 4 cured; operable cases, 14, with 4 cured. The rate of cure in all the cases treated by radium was 4.5 per cent, or one patient out of twenty-two; in the borderline cases 12 per cent, or one patient out of eight; and in the operable cases the rate was 28 per cent, or two patients out of seven. If the advanced cases, in which no cures could be expected, are omitted there were forty-seven operable and borderline cases, of which eight were cured (17 per cent), or one patient out of six.

Passage of Gallstones Through Abdominal Wall.—Davis reports the case of a woman, aged 60, who gave a six months' history of gradually increasing jaundice and loss of weight, with clay-colored stools, dark urine, anorexia and occasional vomiting, preceded by repeated attacks of typical gallstone colic, and extending over a period of twenty-four years. She stated that during this time she had passed through her abdominal wall at intervals thirty-four stones of varying dimensions but usually of the size of small pebbles. They appeared singly or in groups of two or three. Their passage was preceded by the formation of a small swelling under the skin, which, when fomented, discharged the stones externally, leaving the sinus exuding a thick yellow fluid. Abdominal examination revealed the scars of three sinuses, one in the epigastrium and two in the right hypochondrium. A large mass present in the latter region was subsequently diagnosed at operation as an inoperable carcinoma of the gallbladder, this finding being later verified histologically.

Thermal Adjustment of Man and Animals to External Conditions.—While agreeing with Cramer and Cannon that variation in cell combustion, due to varying activity of the suprarenals and thyroid, plays a part in thermal adjustment, and believing that an adaptation of the activity of the thyroid gland is the cause of persisting increase or decrease of resting metabolism after exposure to cold or warmth, Martin thinks they incline to exaggerate the part ordinarily played by this humoral method in thermal adjustment. The experiments of Hildebrandt (1921) on rats, Grafe and Redwitz (1922) on dogs, and Isenschmid (1922) on cats show that an animal some time after thyroidectomy can regulate its temperature by varying production of heat similarly to a normal one, even when the dorsal cord is severed. True, it starts from a lower base line, but failure to compensate is not manifested until the rate of heat loss is considerable. As Isenschmid points out, the thyroid is not the only instrument at the disposal of the organism for thermal adjustment; it has a whole orchestra to play on.

Cog Wheel Breathing.—In order to attempt to clarify the position and to assess the value of cog wheel breathing as a physical sign, a study of 1,000 cases was undertaken by Hebert, consisting of 428 adult males, 409 adult females, and 163 children under 16. In 292 of these, pulmonary tuberculosis was diagnosed, while in the large majority of the remaining 708 no lung lesion was apparent. The inquiry emphasized the fact that cog wheel breathing is of two kinds. In one the interruptions are irregular; in the other they are regular or, to be more exact, they are synchronized with the beat of the heart. Breathing of the first type is uncommon and is rarely, if ever, heard as well marked waves or sharp jerks. In none of the 1,000 cases could it be ascribed to a pulmonary or pleural lesion, and, on the few occasions on which it was heard, it was noticeable only when the patient was breathing forcibly. Hebert holds that for testing the quality of breath sounds forcible respiration should not be used, and, if this rule is adhered to, irregularly interrupted breathing is so rarely heard that it ceases to be of any importance for clinical purposes. Breathing of the second type, on the other hand, is by no means uncommon and can at times be a very striking feature. It appears to be merely a physiologic phenomenon, for which "air waves" is the most suitable term. Air waves were found in 30 per cent of adult males, in 53 per cent of adult females, and in 19 per cent of children under 16 in 1,000 cases investigated. Air waves are not caused by tuberculosis of the underlying lung tissue but are a physiologic phenomenon. Their situation and the demonstration of pressure fluctuations, synchronous with cardiac systole, in the pneumothorax cavity of some patients and in the inspiratory and expiratory currents of air of others, suggest that they are caused by an expansion of the lung compensatory to the contraction of the heart. Certain cases of so-called exocardial murmurs and of pleuropericardial friction are probably merely instances of air waves.

Raynaud's Disease with Paroxysmal Hemoglobinuria.—Bywater relates the case of a child, aged 3 years, who was taken ill six months previously after being aroused from sleep suddenly in the middle of the night and frightened by the intrusion of a drunken man into the house. He had previously been in good health, his only illness having been measles in infancy.

Immediately after the alarming incident the child was noticed to have an attack of pain and coldness of his hands, feet and ears. Several attacks had since occurred, the description of a typical one being as follows: When out in the cold the child would become suddenly doubled up with pain and would cry and have to be taken home at once. The fingers, especially the index finger of one hand, the toes, and sometimes the whole foot and the pinna of both ears would become black and swollen. On arrival home after such an attack the first specimen of urine passed would be dark, but the color of the next specimen would be normal. The child would fall asleep and was frequently quite well on awakening, although nervous and frightened. Such attacks had occurred fortnightly for the past few months and had increased in severity. The case is interesting as illustrating the type of Raynaud's disease occurring in children when the process does not proceed to the stage of gangrene. The syncopal stage is extremely short and is barely noticeable, the asphyxial stage being the one observed. A profound neurotic history in the family, the influence of cold on all occasions, and the comparative rarity of the disease are interesting. It appears to be common in these cases to find a relationship with parental syphilis.

*Biologic Significance of Lung Journey of Ancylostoma Larvae in Normal Host. Yoneji Miyagawa and Ryoichi Okada.—p. 43.
Third Proposal to Use a Phosphoric Acid Ester-Calcium in Treatment of Pulmonary Tuberculosis. Seigo Funaoka.—p. 55.

Significance of Journey of Ancylostoma Larvae in Host.—Miyagawa and Okada have made a careful experimental study of this subject on dogs and rabbits. They found that the rate of oral infection of *Ancylostoma caninum* greatly varies according to the age of the dog. The younger the dog, the greater the rate of infection. The older the dog, the lower the rate of infection. Oral infection rate of the young worms remarkably increases when they pass through the lung of the proper host. If the larvae that gathered together in the lung of the improper host were given orally to the improper host, the greater part of them gather again in the lung of the latter. When the larvae obtained from the lung were given to the proper host, the rate of infection decreased. Young worms that passed through the lung of the proper host, even if they were given to the improper host, nearly lost their ability to come to the lung. They stay in the digestive canal and make development to a fair degree. Ancylostoma larvae, if they pass through the lung of the proper host, obtain ability not only to become adult worms in the intestine of the proper host but also to make development to some extent even in the intestine of the improper host. Summing up these facts, they think that in the case of the infection of *Ancylostoma caninum* no matter whether through the mouth or through the skin, the larvae once pass through the lung of the host and make special biologic metamorphosis and afterward they can complete their development in the intestine. In other words, they believe that the lung journey of the larvae is a preparatory action indispensable for the completion of their future development.

32: 269-360 (April) 1930

Surgical Treatment of Gastric Ptosis by Suspension: Technic and Results. O. Lambret and G. Bizard.—p. 269.
*Pathogenesis of Gastroduodenal Ulcers. A. G. Weiss and C. Hubster.—p. 282.
Treatment of Duodenal Ulcers by Gastrojejunostomy Combined with Duodenal Exclusion. E. Vandeput.—p. 309.
*Electric Bistoury in Gastric Surgery. A. Gullemin.—p. 338.
Pharyngo-Esophageal Diverticula. A. Jentzer.—p. 343.

Pathogenesis of Gastroduodenal Ulcers.—Weiss and Hubster conducted a series of experiments on dogs in an attempt to ascertain the pathogenesis of gastric and duodenal ulcers. They were convinced that the duodenal reflux was in some way involved; the obvious hypothesis was that the reflux of alkaline secretions toward the pylorus and stomach tended to modify the acidity of the gastric juice and that when this alkaline reflux was in any way arrested the resulting hyperacidity of the gastric secretions irritated the mucous membranes and caused ulcers. With this in mind, the authors by a simple surgical process caused a complete deviation of the duodenal secretions in a number of dogs. Within two weeks all the dogs developed definite syndromes of chronic gastric ulcers. However, to the surprise of the investigators, the acidity of the gastric secretions was in no degree intensified. The authors believe now that the relation between duodenal deviation and gastric ulcers lies not in the degree of acidity of the secretions but in the fact that the alkaline duodenal secretions form a protective covering for the gastric and duodenal mucosas that counteracts the irritating effect of the gastric secretions. As a complement to the results obtained by duodenal deviation, deviation of bile was also effected in several dogs. This caused an intense inflammatory reaction in the duodenum and the antrum of the stomach, though not in the fundus, which resulted in acute ulcerous conditions. No large or chronic ulcer appeared, however. It seemed advisable to follow these two experiments with deviation of the pancreatic secretions; however, no satisfactory method was found at the time. Ulcers are found in human beings in the majority of cases in the duodenum, pylorus and antrum of the stomach, which are zones of alkaline or basic secretion, rather than in the fundus, which is a zone of acid secretion. This seems due to the fact that the organs of acid secretion have a stronger native defense mechanism with which to combat irritation of the mucosa. Therefore when the protective influence of the bile and pancreatic juices is removed, ulcers develop more readily in the zones of alkaline or basic secretion, since the duodenal secretions alone do not afford sufficient protection. The authors do not wish to present any dogmatic conclusions as to the cause of the conditions of reflux which seem to constitute the pathogenesis of gastric and duodenal ulcers, nor do they wish to advocate too strongly any particular treatment. They merely present the results of their research, which seem to them logical.

Electric Bistoury in Gastric Surgery.—Guillemin advocates strongly the use of the electric bistoury in gastrectomy because of its excellent aseptic and hemostatic qualities, which eliminate the former risks of infection and cause immediate coagulation of the blood vessels along the surface of the incision. A secondary value of this immediate hemostasis is the fact that the zone of operation is kept clean and it is easy to proceed from one step to the next.

Revue Française d'Endocrinologie, Paris

8: 193-316 (June) 1930

Hypophyseal Hemocrinia. J. Watrin.—p. 193.
*New Pancreatic Hormone, Vagotonin. D. Santenoise, H. Verdier and M. Vidacovitch.—p. 204.
*Hypercrinic Forms of Obestiy. C. Faelli.—p. 261.

New Pancreatic Hormone.—It has long been established that the pancreas produces and secretes a hormone that regulates and stimulates the functional activity of the vagal centers. Santenoise et al., by means of numerous and carefully performed experiments, have proved that the vagotonic power of pancreatic extracts does not belong to insulin, since the effects of insulin on the parasympathetic system are not at all constant and in many cases are negative. Moreover, they have succeeded in extracting from the pancreas a new vagotonic hormone, separated from insulin by a series of precipitations with neutral salts and alcohol.

Hypercrinic Forms of Obesity.—In addition to the forms of obesity caused by hypothyroidism, hypopituitarism and hypo-ovaria, Pende distinguishes three forms due to hypercrinism of the suprarenal cortex, the pancreas (i. e., hyperinsulinism) and the thymus. Faelli gives the clinical history of a typical case of hyperthymic obesity in a boy of 10 years, weight 53.5 Kg., height 142 cm. The fact that the child is physically robust and his body well proportioned, as well as the absence of myxedema, distinguishes this from a case of hypothyroidism. Moreover, the boy began to walk and talk and his teeth appeared at the normal age, which is contraindicative of thyroid deficiency. The lack of segmental distribution of fat and the absence of evident signs of hypopituitary modifications in physical and roentgen examinations eliminate the possibility of a diagnosis of hypopituitarism. Hypo-ovaria is also eliminated by the lack of eunuchoid characteristics of the skeleton. The genitalia resemble in size those of a child of 5 or 6 years, but this is due to prepubescent hyperthymism. The case is also distinguished from the other two hypercrinic forms of obesity. The hypercorticosuprarenal form presents certain characteristic precocious sexual developments, hypertrichosis, and intense psychic excitation, which are entirely lacking here. And in hyperinsulinism there is a lowered glycemia while fasting, while in this case the patient showed a rather high degree of glycemia during a period of fasting. In conclusion, the author feels that the congenital macrosomia, vagosthenic temperament with exaggerated appetite, low diastolic pressure, vascular hypoplasia, dexiocardia and marked obesity observed in this patient are characteristic signs of a state of hyperthymism.

2: 193-288 (Aug.) 1930

*A Particular Anatomic and Clinical Form of Optic Neuromyelitis. G. Marinesco, S. Draganesco, O. Sager and D. Grigoresco.—p. 193.
Roentgenograms of Basal Bones of Skull in Children. V. Christiansen.—p. 229.

A Particular Form of Optic Neuromyelitis.—Marinesco et al. describe a case of a peculiar form of optic neuromyelitis that also presents some characteristics of encephalitis periaxialis. Medullary lesions were found which were clearly indicative of optic neuromyelitis. On the other hand, cerebral lesions affecting the white matter and causing myelinic disintegration with relative conservation of the axis cylinders were suggestive of Schilder's encephalitis periaxialis. The authors feel that it is difficult, if not impossible, to decide to which disease such cases belong even after careful anatomic and clinical examination. They consider these cases as links between optic neuromyelitis and Schilder's disease, which they regard as two separate infections, which have nevertheless a certain relationship.

Annali Italiani di Chirurgia, Naples

9: 615-720 (July 31) 1930

*Differential Value of Serologic and Biologic Reactions in Study of Certain Pathogenic Species of Streptothrix. O. Bartoli.—p. 615.
*Surgical Treatment of Experimental Pancreatic Diabetes by Means of Suprarenalectomy. G. Perrotti.—p. 631.
Mesenteric Cysts of Suprarenal Origin. C. Trinchera.—p. 646.
Glycemia and Hyperglycemic Curve in Simple and Complex Calculosis of Liver. G. Stirpe.—p. 665.

Differential Value of Serologic and Biologic Reactions in Study of Certain Pathogenic Species of Streptothrix.—Bartoli describes a case of infection due to *Streptothrix carnea*, observed in a man, aged 27. He isolated the fungus, studied the cultural characters and points out an accentuated macroscopic and microscopic polymorphism. These cultural data and research carried out with deviation of complement, cutireaction and intradermal reaction, in which antigens prepared from the streptothrix in question and from others secured from other institutes were employed, lead the author to think that there is a close relationship between these various types of streptothrix, so that it is difficult and at times impossible to make a subdivision or a frank classification based on cultural and serologic characters.

Treatment of Pancreatic Diabetes by Means of Suprarenalectomy.—Perrotti concludes from his experiments that the removal of a suprarenal in a dog has a marked influence on the course of experimental diabetes due to the complete removal of the pancreas; it lowers notably the glycemic curve and renders less grave the clinical symptoms of diabetes. These effects are, however, temporary, for a compensatory hypertrophy on the part of the remaining suprarenal is established and the experimental diabetes resumes its grave and fatal evolution.

Riforma Medica, Naples

Acute Chorea and Catalepsy. G. Marinesco, A. Kreindler and E. Cohen.—p. 1191.
A Rare Case of Phthisis Associated with Echinococcus. G. Pennetti.—p. 1194.
*Experimental Researches on Glycogenic Functioning of Liver in Traumatic Shock. A. Scarpello.—p. 1198.

Research on Glycogenic Functioning of Liver in Traumatic Shock.—Scarpello's researches induce him to conclude that in traumatic shock the increase in the blood sugar is due chiefly to an alteration of the glycoregulatory functioning of the hepatic cells. It is not easy to give an explanation of this phenomenon. It is probable that various factors act on the liver and increase the glycogenic functioning. By way of a simple hypothesis, it might be assumed that the traumatic shock acts reflexly on the functioning of the liver or in other words, that the shock causes disturbances in the field of the sympathetic nervous system, which in turn act on the hepatic cells and increase the glycogenolytic functioning. On the other hand, it is not impossible that the disturbing movements of the intestine cause an absorption by the portal system of toxic substances, which, as has been shown for various toxins (Delbet, Marmier), may stimulate the hepatic cells to an increased glycogenolysis.

*Ethylhydrocupreine in Pneumococcal Meningitis. B. Moyano Navarro.—p. 198.
*Lavage of Stomach in Treatment of Pyloric Syndrome of Infants. E. Martinez Zuviria and F. Manchaca.—p. 203.

Ethylhydrocupreine in Pneumococcal Meningitis.—Moyano Navarro reports a case of pneumococcal meningitis, proved by bacteriologic examination, with purulent cerebrospinal fluid, in a child, aged 13 years, in whom recovery was obtained after three intraspinal injections, each of 5 cc. of a 2:1,000 ethylhydrocupreine solution. No visual disturbance was caused by the administration of the drug. The pneumococci rapidly disappeared from the cerebrospinal fluid after the first injection and a slow improvement in the clinical picture followed. The treatment was stopped after the second injection, but aggravation of the patient's condition led to the administration of the third injection. After this injection the patient's condition improved until recovery ensued, with restitution to normal of the cerebrospinal fluid from the bacteriologic, cytologic and chemical points of view.

Lavage of Stomach in Treatment of Pyloric Syndrome of Infants.—Martínez Zuviría and Manchaca consider lavage of the stomach a simple and efficient procedure which renders great benefits in intractable vomiting of infants caused by pyloric stenosis. The authors report the case of an infant, aged 2 months, with a grave picture of recurrent vomiting, denutrition and dehydration. A change of diet and subcutaneous injections of mother's milk (with the aim of provoking desensitization) and the administration of several drugs failed. After three lavages of the stomach (in which a large amount of glairy liquid was expelled) complete recovery ensued.

*Value of Determination of Urea Content of Saliva. S. Larregla.—p. 189.
Orthoclinostatic Reaction. J. H. Blair Callejas.—p. 190.

Value of Determination of Urea Content of Saliva.—Larregla says that saliva contains urea in variable amounts and in a concentration proportional to that of the blood, both in normal and in pathologic conditions. The author made a comparative study of the concentration of urea in the blood and in the saliva of normal persons and of patients with renal and other disturbances (nephritis, renal sclerosis, tuberculosis of the kidneys, gonococcal and colibacillary pyelitis, myocarditis with and without edema, arteriosclerosis, cirrhosis of the liver, catarrhal jaundice, cancer of the stomach, gastritis, bronchitis, acute or chronic rheumatism, gout, lymphangitis and neurasthenia). In normal persons the urea content of the saliva is just a little below that of the blood. In patients whose kidneys eliminate large amounts of urea, the urea content of the saliva is higher than that of the blood. Generally speaking, however, the values of both are so close together that the determination of the concentration of urea in saliva seems to be a simple method worthy of being popularized. The method is especially indicated in cases in which the withdrawal of blood presents difficulties. The method is contraindicated in patients with suppurative lesions of the mouth, because in those cases the amount of urea increases. The amount of saliva necessary for the determination of the urea content is from 5 to 10 cc. The saliva should be subjected to the same treatment that is used with blood when an estimation of the urea content is going to be made; viz., it is necessary to coagulate the albumins, by mixing the saliva with an equal volume of a 10 per cent solution of trichloracetic acid and then filtering it.

*Indications for Extirpation of Spleen During Childhood. H. Hirsch-Kauffmann.—p. 1476.
Surgical Diathermy in Diseases of Nose and Throat, Especially in Malignant Tumors of These Organs. W. Hesse.—p. 1479.

Acute Ascending Spinal Paralysis During Pregnancy.—Hornung and Creutzfeldt describe two cases of acute ascending spinal paralysis. The clinical aspects and the microscopic changes indicated that in one case pregnancy toxicosis had caused the disease; in the other instance, however, the disturbance was intercurrent and had the aspects of acute anterior poliomyelitis. The authors think that in cases caused by pregnancy toxicosis interruption of the pregnancy is advisable. The acute anterior poliomyelitis that occurs during pregnancy seems to be of the same severity as that observed in small children. In spite of the fact that such cases are almost hopeless, interruption of the pregnancy is nevertheless advisable in order to improve the ventilation of the lungs.

Indications for Extirpation of Spleen During Childhood.—Hirsch-Kauffmann first discusses the physiology of the spleen. In view of the great significance of the function of the spleen, it seems that its extirpation would always lead to grave disturbances; however, the spleen is only a part of a whole system and following the removal of the spleen the other parts of the system compensate for its loss. The cases in which secondary involvement of the spleen necessitates its extirpation are comparatively rare. In the literature there is reported the case of an adult in whom splenectomy became necessary on account of adhesions with an unusually large retroperitoneal lipoma. Traumatic rupture of the spleen necessitates extirpation in order to avoid fatal hemorrhage. Tumor of the spleen is not always an indication for splenectomy. In such conditions as exudative diathesis, syphilis, malaria, typhoid, sepsis and leukemia, extirpation of the spleen is contraindicated in spite of the presence of the splenic tumor, because splenectomy would weaken the diseased organism. In spite of favorable results in several cases of leukemia, splenectomy is not advisable in such cases on account of the danger of fatal hemorrhage. The engorged spleen in heart disease requires internal treatment. In cases of endocarditis lenta, in which the spleen causes a new bacterial invasion, splenectomy might be advisable not only because it eliminates the source of infection but also on account of the stimulation of the erythropoiesis and of the leukopoiesis. In discussing the various forms of anemia the author points out that in pernicious anemia, which is rare in children, splenectomy brings only temporary improvement, and in pseudoleukemic anemia, which is characteristic for small children, internal therapy brings better results than surgical intervention. In familial splenic anemia (Gaucher's disease) splenectomy has only a symptomatic significance because it effects a temporary improvement of the anemia and of the leukopenia and thrombopenia. In Banti's disease, extirpation of the spleen is particularly effective when it is done during the first two stages of the disease. In purpura haemorrhagica splenectomy has likewise proved effective. In thrombosis of the splenic or portal veins, provided the diagnosis is made early, extirpation of the spleen might save the life of the patient. Especially effective is splenectomy in congenital hemolytic icterus. The author observed favorable results in five cases and he thinks that in these cases splenectomy is the only effective therapy.

High Degree Increase in Thrombocytes. O. B. Bode.—p. 1587.

Sedimentation Speed of Erythrocytes in Thyrotoxicoses.—In patients with thyrotoxicosis, who received roentgen treatment, Hufschmid determined simultaneously with the basal metabolism also the sedimentation speed of the erythrocytes. He found that the sedimentation was normal in 50 per cent of the cases. The increase in the other cases rarely exceeded 4.6 per cent. The observations show that the sedimentation speed cannot be considered an indicator of the efficacy of therapeutic measures. In patients with thyrotoxicosis, who had been cured with irradiations and who before the treatment had had an accelerated sedimentation speed, the sedimentation was not always completely normalized.

Action of Insulin on Gastric Secretion.—Meyer asserts that the opinions of investigators regarding the influence of insulin on the gastric secretion differ widely. Considering that the correct understanding of this problem is not only of theoretical interest but has also therapeutic and diagnostic value, he made careful tests on fifty patients. Most of them were free from gastric disorders, but some had achylia. In the majority of the patients the metabolism was likewise normal; however, eight had diabetes. The author's observations are summed up as follows: In persons free from achylia the acidity of the stomach increases regularly from seventy-five to ninety minutes after the injection and in most instances the quantity of the gastric juice likewise increases. Control tests with protein proved that the increase is due to the insulin itself and not to the protein contained in the insulin. The increased gastric acidity following insulin injection is an early symptom or a partial manifestation of hypoglycemia, because the blood sugar curve corresponds inversely to the gastric secretion; the blood sugar is lowest when the gastric secretion is highest. Diabetic patients do not show a gastric reaction, if they do not develop hypoglycemia. However, if a person with diabetes develops hypoglycemia, then he likewise shows an increase in the gastric secretion, but usually the increase is less pronounced than in persons without metabolic disorders. Among the patients with anacidity insulin may be used to detect those with incomplete achylia. Insulin should not be employed in patients without metabolic disturbances but with hyperacidity, because the insulin will increase the acidity still more. However, insulin is helpful in the forced feeding of persons with subnormal acidity, with lack of appetite or with anacidity.

Caffeine in Hypoglycemic Conditions Resulting from Overdosage of Insulin.—Popper and Jahoda point out that insulin poisoning or the hypoglycemic syndrome can be counteracted by the administration of dextrose. This might indicate that the dextrose increases the blood sugar and thus nullifies the action of the insulin. However, it has been found that the toxic effects of overdosage of insulin may be counteracted by substances such as liquid petrolatum oil and protein that do not influence the blood sugar content. Even such substances as epinephrine, which really have a hyperglycemic action and do counteract insulin poisoning, do not become effective by way of the blood sugar. On account of its detrimental effects on the circulation epinephrine, however, is not advisable in insulin poisoning. It was discovered that caffeine has the same action on the toxic effects of insulin as epinephrine, without giving rise to undesirable complications. The authors investigated this action of caffeine in self tests and in tests on other physicians and students who were free from metabolic disorders. The results of the tests convinced the authors that the symptoms of insulin poisoning are not entirely dependent on the decrease in the blood sugar. By the administration of caffeine the manifestations of insulin intoxication may be counteracted without any changes in the decreased blood sugar. Therefore the authors assume that insulin contains a component that influences the sympathetic centers and thus causes the hypoglycemic syndrome.

Symptom of Facial Paralysis.—Wartenberg directs attention to the fact that, if a normal person closes the eyes and if an attempt is then made to lift the upper lid with the finger, one perceives a vibration in the orbicularis oculi. In facial paralysis this vibration is absent. On the basis of two years' experience with this symptom the author comes to the conclusion that it is a valuable aid in the diagnosis of peripheral facial paralysis and should be further investigated.

Freezing of Sciatic Nerve for Treatment of Juvenile Gangrene.—Freezing of the sciatic nerve by means of a carbon dioxide apparatus was done by Läwen in three cases of juvenile gangrene. He points out that freezing of a mixed nerve has a therapeutic effect not only because of the interruption of the sensory nerve tract but also because of its influence on the vasoconstrictors. The increased temperature on the sole of the foot indicates a better blood perfusion of the peripheral vessels. If freezing is done for a sufficient length of time, the severe pains disappear immediately; in some instances there develop paresthesias of varying severity. The freezing of the sciatic nerve also shows whether the gangrene is of a benign or a malignant form. In the benign forms the gangrene does not progress after the freezing of the sciatic nerve. Another advantage of the freezing is that within several days the correct site for the amputation can be found. The author gives detailed case reports and discusses the significance of the various aspects.

Acid Diet for Treatment of Bronchial Asthma.—In order to determine whether patients with bronchial asthma incline more to acidity or alkalinity, Tiefensee tested the acidity of the urine. He found that in patients who had not been treated there were periodic changes in the hydrogen ion concentration, in the acid and in the ammonia contents. At the beginning and during the most severe stage of an attack the hydrogen ion concentration was high but the acidity and ammonia levels were low. During the attack-free interval the conditions were reversed. After the author had found that an attack of asthma could be checked when the acidity of the blood had been increased by letting the patient breathe a mixture of air containing from 5 to 8 per cent of carbon dioxide, he attempted to counteract the alkalosis by an acid diet. When the patients were placed on an acid diet with the addition of salts inducing acidity, such as ammonium chloride or ammonium phosphate, the reaction became acid and the asthma attacks became milder or ceased entirely. When patients with asthma were treated by means of the allergen-free chamber, the amount of acid excreted in the urine was likewise increased. But a complete improvement was obtained only when the acid diet was also instituted. In these cases the quantities of acid excreted in the urine were considerably larger than in patients who had not been in the allergen-free chamber. The author comes to the conclusion that even if alkalosis is not the cause of asthma, it is nevertheless a significant symptom and can be counteracted by a diet inducing acidity. He also discusses the possibility whether other means besides the acid diet may effect an acid modification of the blood and tissue reactions.

Treatment of Malignant Diphtheria.—Kundratitz reviews several theories regarding the nature of malignant diphtheria. According to some investigators who have detected streptococci in some cases, it is a mixed infection. Streptococci are not found in all instances, however, and the author is inclined to believe that malignant diphtheria is the severest poisoning with diphtheria toxins. He thinks that in this form of diphtheria the toxins are absorbed by the cells to such an extent that the antitoxin neutralization in the tissues is no longer possible. On the basis of experiments by Fröhlich and Zak, the author attempted a combination therapy with diphtheria serum and with theophylline. The latter was employed to increase the tissue permeability. The author made experiments on guinea-pigs and found that among the animals that had been subjected to the combination therapy the mortality was considerably lower than among those that had received only serotherapy. After observing favorable results in the animal experiments, he employed the combination therapy in a children's hospital; and, although not all children with malignant diphtheria could be saved, the mortality rate was nevertheless considerably lower than when only serum was administered. The author describes the technic of the treatment and points out that the circulation should be watched carefully. On account of the diuresis that may result, it is also essential that the patient receive a sufficient amount of fluids.

Peculiar Bone Disease in a Nursling.—Roske reports a case of a hitherto undescribed disease of the long bones that he observed in a nursling. The infant's parents were healthy and had one other child. The second child was born at term and weighed 7 pounds (3,175 Gm.). During the first four weeks of life he appeared normal and developed well. At the end of this time, however, the mother noticed two swellings on the right leg and a short time later a similar swelling on the left leg. The infant became restless, cried a great deal, drew the legs high up and apparently had severe pain, particularly when the legs were touched. Shortly before his admission to the hospital the swellings had become more marked but the infant did not have fever, drank well and had normal stools. A physician who was consulted made a diagnosis of a healing fracture. On admission to the hospital the infant was found to be strong and well developed with solid, regularly distributed fat pads, good turgor, and ruddy cheeks; the skin and visible mucous membranes were of normal color. The infant weighed 4,500 Gm. and was 53 cm. long; the circumference of the head was 40 cm. and of the thorax 38 cm. He held his legs drawn up on the abdomen and cried when they were handled. Both tibias were thickened in their middle third and were hard and highly sensitive; the thickenings were smooth and spindle-shaped and the overlying skin was normal and not adherent. Similar swellings could be felt also in the distal ends of both radii, but these were much smaller and less painful and involved only a small portion of the shaft. Another swelling was found in the distal end of the right humerus. The physical examination was otherwise negative, as were Wassermann reactions in the blood of both the child and the parents. Examination of the blood of the infant revealed a shifting of the leukocytes to the left. In a roentgen examination of both tibias it was found that about the shafts of both bones at the level of the external swellings there was a thick mantle-shaped shadow of almost the same density as the shadow of the shaft. Since the condition did not seem to conform to any of the known bone diseases, a biopsy was performed on the left tibia. The periosteum was found to be thickened and gelatinous but the underlying bone was of normal appearance, slightly softer than normal and highly vascularized. A delimitation between the shaft of the tibia and the overlying bone noted roentgenologically was impossible. Although macroscopically the condition resembled syphilitic periostitis, microscopic examination of the excised periosteum, pieces of bone, and bone marrow did not disclose the changes characteristic of syphilis. The swellings increased slowly in size and then, although the patient was not given special treatment, they began to decrease in size and after nine months they had disappeared completely. Despite the careful examinations and study of the case it was impossible to make a diagnosis.

Modification of Circulation by Psychic Processes. W. Bier.—p. 762.
Diastase Content of Blood in Communicable Diseases. W. Grunke.—p. 782.

Acidity of Gastric Juice in Pulmonary Tuberculosis.—Rave gives the results of a study of the acidity of the gastric juice in thirty persons with moderately severe or severe pulmonary tuberculosis. He noted that the acidity seemed to be independent of the type and extent of the pulmonary process. It did, however, seem to be dependent on the duration of the disease because persons who had been under observation for a long time were always found to have either subacidity or anacidity.

Treatment with Animal Blood of Exophthalmic Goiter.—In the treatment of 120 patients with exophthalmic goiter, Zimmer used Bier's method of intramuscular injections of sheep, beef and horse blood. In even severe cases of the disease in which the patients had been under internal treatment for a long time and had been sent in for surgical treatment he was able by mean of injections of animal blood to cause a complete disappearance of the symptoms and maintain the patients free from recurrence for several years. This form of treatment, however, does not usually greatly modify the exophthalmos; severe toxic injuries of the heart and conduction disturbances are likewise not influenced. Since the size of the goiter remains unchanged, operation is indicated in all cases in which mechanical obstruction is present. In the few cases in which it was necessary to operate on the patient because of the size of the goiter, it was noted that the patients supported the operation much better than did patients who had not received treatment wih animal blood.

Blood Smears and Differential Counting of Leukocytes: Technic.—On the basis of a comparative study of the two methods of making blood smears and differential counts of leukocytes, Plonskier states that Schilling's method is not only less complicated but just as accurate as Goldmann's method.

*Expulsion of Fibromyoma Following Abortion. W. Borochowitsch.—p. 2144.

Pathologic Anatomy of Female Vertebral Column: Pathogenesis of Gynecologic Backache.—Übermuth investigated the question of whether backaches in women may be due to pathologic changes in the vertebral column. His observations are summed up as follows: In the intervertebral fibrocartilages, especially in those of the lumbar region, there develop areas of degeneration. They usually become manifest at the end of the second and at the beginning of the third decade of life. The sequelae of the degeneration, such as disintegration of the nuclei, formation of cartilaginous nodules and degeneration of the medullary connective tissue, may lead to spondylitis deformans. Changes developing with advancing years lead to a decrease in the elasticity, and this results in an uneven distribution of pressure and traction forces on the vertebral column. Such unequal burdening may cause pains in the periosteum-muscle apparatus. These conditions alone may cause backache, but besides these there are certain factors that influence the female vertebral column; namely, pregnancy, certain occupations, and a protective position that is assumed in some gynecologic diseases.

Ventrovesicofixation of Uterus.—Jülich points out that among the numerous surgical methods that are employed for the correction of the position in retroflexion of the uterus there are few that give entirely satisfactory results. A modification of Olshausen's method that was first employed by Werth, he considers as the most advantageous. He describes the technic as follows: After the abdominal cavity has been opened by means of Pfannenstiel's incision, the uterus is drawn toward the back and upward, so that the plica vesico-uterina is brought out. With the aid of clamps placed along the plica, the peritoneal covering of the plica, by means of a catgut suture, is made into a ruff. This suture also grasps the uterus below the attachment of the round ligament. A catgut suture is then put around the ligaments near where they leave the uterus, and on the anterior wall of the abdomen the suture grasps besides the peritoneum also the sheath of the rectus, the rectus muscles and the fascia. While the abdominal wall sutures are drawn, the vesical ruff suture is made. Then follow the abdominal wall sutures from the inside, and the two last knots are connected by a continuous catgut suture. It was pointed out that the connection of the uterus with the bladder might be a disadvantage during pregnancy in that during enlargement of the uterus the bladder might likewise be forced upward. However, observations on patients who underwent the operation did not justify this fear, for none of them complained of bladder trouble, and examinations likewise did not reveal abnormalities. That bladder disorders do not develop is due to the fact that not the bladder itself but rather its peritoneal covering is connected with the uterus. Another thing that was feared was that the vesical ruff suture might become cicatrized and might hinder the enlargement of the uterus. However, the author did not observe this complication and he thinks that in Werth's method of ventrovesicofixation the danger of formation of a scar tissue ligament is not more pronounced than in other methods. He gives several case reports and then compares Werth's method with several others. In most of them the results are far less favorable. The Alexander-Adams operation is perhaps the best method when pregnancy and confinement are considered, in that it reestablishes entirely normal anatomic conditions. However, a disadvantage of the method is that the uterus frequently resumes the old retroflexion. The author comes to the conclusion that Werth's method gives the most favorable results.

Tumor of Omentum.—Joachimovits reports the case of a woman, aged 66, who had a tumor of the omentum. He gives the anamnesis and describes the symptoms and the operation. The microscopic examination of the tumor revealed a fibromyoma. The author reports this case not only because tumors of the omentum are comparatively rare but also because of the typical gynecologic anamnesis (twenty years previously supravaginal myoma operation) and on account of the differential diagnosis.

Expulsion of Fibromyoma Following Abortion.—Borochowitsch reports the case of a woman, aged 27. The anamnesis revealed two spontaneous births several years previously, and an artificial abortion in the second month of pregnancy ten months previous to the hospitalization. Her present ailment had begun two months before she came to the hospital. Examination revealed a uterus enlarged as in a gravidity during the fourth month; the cervix uteri was dilated and the os uteri was open. By means of the abortion forceps the ovum was removed. It showed the development of the second month of pregnancy. Curettage and examination of the uterine cavity revealed a tumor on the posterior wall. Six days after the abortion the patient was discharged from the hospital. However, ten days later she complained of severe pains, and examination revealed that the tumor extended into the cervix uteri. On account of the size of the tumor and its location, supravaginal amputation was done in preference to the vaginal operation. The tumor had a circumference of 25 cm. Microscopic examination revealed a fibromyoma. The author thinks that the submucous myoma had caused the abortion and that the contractions of the uterus had caused the expulsion of the tumor.

Suggestions for Investigation of Rheumatic Cases.—As the data and experience of workers scattered over many countries are now being compared and discussed, Fox feels that it would be convenient if all students of rheumatism could abandon for the present all attempts at definition and describe their cases in clinical groups or types. He suggests that the principle of age groups should be followed. Age profoundly modifies all rheumatic conditions. In such age groups cases are recorded in tabular form, arranged in columns showing family and personal history, factors of causation, mode of onset, organic and functional abnormalities, and so on. In his own experience these age groups have become characteristic clinical types, with a differing etiology. He invites workers in arthritis to divide their cases into: 1. Arthritis of the young, a disease mainly in women. 2. Arthritis in middle age, in both sexes, and with particular incidence in women at the climacteric. 3. Arthritis in the old. Another mode of grouping cases will appeal to those who are in charge of treatment centers—the therapeutic classification. Conditions of ill health that react similarly under treatment are either of a similar nature or in a similar phase of disease. If a hundred patients with arthritis were submitted to the same treatment they could be usefully classified according to the reactions that they manifested.

Rheumatic Conditions in Animals and Men.—Wester discusses the etiology of: (*a*) genuine idiopathic chronic arthritis deformans; (*b*) arthritis deformans juvenilis (Perthes); (*c*) chronic arthritis deformans after acute polyarthritis, and (*d*) acute polyarthritis. He points out that it is more or less a question of chance if the bacilli are found in the synovia in the bacterial articular infection and therefore does not think it justifiable, when no bacteria are present in the synovial fluid, to come to the conclusion that an arthritic process is not bacterial but toxic, which is the tendency in pathologic conditions (focal infection) in man.

*Diagnostic Value of Colloid Reactions in Cerebrospinal Fluid. A. V. Neel and P. Dickmeiss.—p. 697.
*Gastric Glioma: Case. S. Harild.—p. 706.
Distribution of Lead in Organism. S. Lomholt.—p. 713.

Diagnostic Value of Colloid Reactions in Cerebrospinal Fluid.—Neel and Dickmeiss state that the colloid reactions give no information in differential diagnosis beyond that afforded by determination of the albumin. They therefore see no reason for introducing these reactions into the routine laboratory examinations of the spinal fluid when, in addition to cell count and Wassermann test, quantitative globulin-total albumin determination is made.

Gastric Glioma.—In this typical case, in a woman, aged 72, with *probable diagnosis of ovarian cyst with a long pedicle,* laparotomy revealed a tumor the size of a child's head, situated in the lesser curvature and posterior wall of the stomach. Resection of the stomach was necessary for removal of the tumor. The microscopic diagnosis was peripheral glioma ("schwannoma"), presumably benign. Complete recovery followed. Harild says that the possibility of malignant transformation of a glioma is slight but there is danger of profuse bleeding on rupture of the necrotic cysts, and unless operative treatment is otherwise contraindicated, the tumor should be removed; often only a minor intervention is necessary. The outlook for permanent recovery after removal of the tumor is good.

*Cutaneous Reflex Hyperalgesia of Thighs in Inflammation of Adnexa in Women. O. Jersild.—p. 721.
*Experiments on Rats with Diet Deficient in Carbohydrates and Vitamin B. S. V. Gudjonsson and A. M. With.—p. 733.
Length of Life of Consumptives with Tubercle Bacilli in Sputum. C. J. Jacobson.—p. 738.

Cutaneous Reflex Hyperalgesia of Thighs in Inflammation of Adnexa in Women.—Cutaneous hypersensibility of the thighs was demonstrated by Jersild in about 70 per cent of fifty cases of acute salpingitis or exacerbations of old inflammations in the adnexa. The hyperalgesia has a typical and constant localization on the lateral aspect of the thigh, somewhat forward, between the middle and lower thirds of the femur. The tenderness is not equally marked in the hyperalgesic zone, but there is a maximal point, always about from 12 to 15 cm. above the knee. Two cases are described.

Experiments on Rats with Deficient Diet.—In these experiments on rats fed on vitamin B, Gudjonsson and With found that the animals also without carbohydrates in their diet fared better than those with starch, and sometimes lived up to twenty weeks. Those to whose diet yeast was added were normal. The studies are to be continued.

73: 749-760 (July 10) 1930

*Studies on Jaundice. T. Geill.—p. 749. C'td.
*Iso-Agglutinin Content of Retroplacental Blood. C. Hamburger.—p. 757.

Studies on Jaundice.—Geill's material comprised 43 ambulant patients, 31 of whom had acute epidemic hepatitis. Of the 15 women only 3 had bradycardia, of the 28 men, 21. Hypotension was noted in 10 women and 12 men. The diastolic blood pressure was reduced in some cases with normal systolic pressure, so that the pulse amplitude was increased. The frequent capillary pulse is attributed mainly to a dilatation of the small vessels but also in some cases to the relatively large pulse amplitude.

Iso-Agglutinin Content of Retroplacental Blood.—Hamburger determined the iso-agglutinin content of retroplacental and cubital blood in sixty cases and found a marked reduction in the retroplacental blood of the agglutinin homologous with the blood corpuscles of the fetus. It is suggested that a slight mixture of liquor amnii with the retroplacental blood may explain this phenomenon.

THE RÔLE OF THE CLINICAL PATHOLOGIST *

ARTHUR H. SANFORD, M.D.
ROCHESTER, MINN.

It is evident from the title of my paper that the Section on Pathology and Physiology may not have followed precedent in honoring me by election to the chairmanship of the section. The last chairman was a physiologist, and according to custom I should be a pathologist. However, as my field is distinctly known as "clinical pathology," I shall present for your consideration my views as to the relationship of the clinical pathologist to the physiologist and to the medical profession in general.

This section of the American Medical Association has existed in its present form for almost thirty years, and it came into being as part of the evolution of modern medicine. It represents the realization of ideas somewhat vaguely formed in the minds of the early founders of the Association. As you know, the American Medical Association grew out of the meetings of the National Medical conventions held in 1846 and 1847. The first meeting of the American Medical Association as such was in Baltimore in 1848. The history of the Association can be easily traced by referring to the transactions which were published yearly. The name of Nathan Smith Davis appears most prominently throughout the proceedings in those early years. At a meeting in Philadelphia in May, 1855, a resolution was introduced by Nathan Smith Davis advocating the separation of meetings into business sessions in the morning and scientific sessions in the afternoon. These resolutions were considered the next year (1856), at the first meeting ever held in Detroit. They were not received entirely with favor, because, as stated in the committee's report: "To a few who are gifted with colloquial powers, and to others who have undergone the discipline required to fit them for public debate, the interest of the meetings conducted upon the plan proposed in the resolutions would be greatly increased, but as the great body of the Association would, voluntarily it is true, be excluded from participating in these exercises, the enthusiasm which now characterizes our anniversaries would subside, and with it the professional *esprit de corps* . . . the Committee respectfully asks to be excused from submitting a distinct proposition on the subject."

The plan was subsequently adopted, and it is interesting to note that the Detroit meetings have always been of great importance to the American Medical Association. At the second meeting of the National Medical Association in 1847, it was proposed to have a Section of Medical Jurisprudence, Hygiene and Physiology. The sections of the Association seemed to have consisted really of committees to stimulate interest in, and to make reports on, subjects pertaining to the fields mentioned. The first activity of such a section seems to have been at Baltimore, in 1866. However, there was no discussion of anything pertaining to physiology. At the Washington meeting in 1870, just sixty years ago, Joseph G. Richardson, microscopist to the Pennsylvania Hospital, Philadelphia, presented a paper entitled "On the Cellular Structure of the Red Blood Corpuscle." This paper, presented before the Section of Medical Jurisprudence, Hygiene and Physiology, stimulated the appointment of a committee with Richardson as a member to make microscopic research on the structure of the white blood corpuscles and to report at the next meeting of the Association. The report was not made until two years later. That the Association manifested great interest in physiology at the Washington meeting was also evidenced by the fact that Dr. Henry Noel was requested to prepare a paper "on such physiological subject as he may select to be read before the next meeting." It was also moved that the permanent secretary be asked to urge members to write papers on physiology to be read before the Section of Medical Jurisprudence, Hygiene and Physiology.

The next meeting was in San Francisco in 1871. It appears that the section was not active at this meeting but the prize essay of the Association by Edward H. Taylor was on "The Chemical Constitution of Bile." Taylor chose as a motto for his thesis, probably facetiously, the significant quotation from Burton's Anatomy of Melancholy, "'Tis hard, I confess, yet nevertheless, I will adventure through the midst of these perplexities and, led by the clew or thread of the best writers, extricate myself out of a labyrinth of doubts and errors."

At the meeting in Philadelphia in 1872, the Section of Medical Jurisprudence, Hygiene and Physiology presented Richardson's "Report on the Structure of the White Corpuscle." Henry Harthorne, chairman of the Committee on Arrangements, read a paper entitled "On the Present Condition of Vasomotor Physiology." His committee also announced as an attraction the preparation of a museum, or collection of objects of scientific and professional character, and also an exhibition of microscopes and microscopic objects offered by the biologic and microscopic section of the Academy of Natural Sciences.

At St. Louis, in 1873, a special committee reported on "A plan for the better arrangement of the sections and for the more rigid examinations of papers offered for publication." It was resolved that the Association meet for business sessions from 9:30 a. m. until 1:30 p. m. and that the sections meet from 3 p. m. to 5 p. m. for presentation of papers. The proposed sections were:

---

* From the Section on Clinical Pathology, the Mayo Clinic.

* Chairman's address, read before the Section on Pathology and Physiology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

1. Section of Practical Medicine, Materia Medica and Physiology.
2. Section of Obstetrics and Diseases of Women and Children.
3. Section of Surgery and Anatomy.
4. Section of Medical Jurisprudence, Chemistry and Psychology.
5. Section of State Medicine and Public Hygiene.

The meeting in 1874 was in Detroit. Nathan Smith Davis was the first chairman of the Section of Practical Medicine, Materia Medica and Physiology, and the plan that he had proposed eighteen years before and which had received little encouragement at the former Detroit meeting was put into effect. It might be mentioned in passing that the newly formed Section of Medical Jurisprudence, Chemistry and Psychology had two meetings in Detroit. At the first session only the chairman and secretary were present, and the meeting was adjourned. At the next session there were four members present, including the officers. The chairman and secretary each read a paper and the meeting was adjourned.

Joseph M. Toner, in the presidential address, estimated the number of separate diseases known to the profession to be 2,400. He prophesied that this number would be reduced as knowledge of physiology and pathology advanced. He furthermore stated, "There are some hundreds of young physicians, of first-class ability, noted for their originality of thought and boldness of investigation, residing in different parts of our country, who are working with scalpel, the microscope, and test-tube in the spirit of true philosophers. But where we have ten such, we ought to have a hundred. It is from among such must come the leading medical men of the future."

For another eighteen years the sections met as planned. During this time most of the papers on pathology were presented in the Section of Surgery and Anatomy. In 1892, again in Detroit, a new section went into effect, the Section of Physiology and Dietetics, which continued for eight years. In 1900, on a resolution of Dr. Hektoen, the Section of Pathology and Bacteriology was formed. The next year, however, in St. Paul, the Section of Physiology and Dietetics and the Section of Pathology and Bacteriology were fused to form the Section on Pathology and Physiology, with the plan to have a physiologist as chairman every third year.

I have spent too much time, perhaps, in tracing the history of this section, but I have tried to show how the minds of the profession have been drifting in their ideas of the relationship of these two fundamental branches of medicine. The physiologist has ever been the pioneer for the internist, and the histopathologist has ever been the mainstay of the surgeon. Without going into specific details I think I may safely say that the physiologist usually has been about a decade ahead of the remainder of the profession. But as his activities in the American Medical Association became closely associated with those of the pathologist, we find that he is thinking and talking more and more of pathologic physiology, of alteration of the functions of the various organs of the body when affected by disease, and of deviations from the normal produced by pathologic conditions. So within the last thirty years there has developed what is now recognized as a separate specialty in medicine, that of clinical pathology.

What is a clinical pathologist? To certain members of this section this query will have a familiar sound. It has been discussed and defined many times, particularly by the American Society of Clinical Pathologists. A clinical pathologist is a physician who devotes all or the major portion of his time to diagnosis of disease by laboratory methods. He is a histopathologist and microscopist. He must be a serologist, a bacteriologist and to some extent a parasitologist, a hematologist and somewhat of a chemist and physicist. In this field of varied interests he must always be up to date and must serve chiefly as a consultant in interpreting and evaluating laboratory data for his medical brethren.

Most clinical pathologists in America are devoting part of their time to histopathology. They are often surgical pathologists called on to make diagnoses by the use of frozen sections and to make biopsies generally. They will often also conduct necropsies, and hold clinicopathologic conferences. In connection with such work there may also develop an opportunity for research in histopathology. In most universities, the clinical pathologist and the field of clinical pathology may be somewhat subordinate to general pathology, although in hospitals and in small group practice this is not true, as the clinical pathologist is also the general pathologist.

To the physiologist and physiologic chemist the clinical pathologist owes a great debt, for it is his research of yesterday that so often provides the methods for the laboratory procedures of today. The newer methods for estimating chemical changes in the blood, developed by active physiologic chemists, constitute many diagnostic methods that are of daily use in the clinical laboratory. The same debt is owing to the closely related investigators in serology and in immunology. Without the ready application of these methods, developed in the last twenty years, clinical pathology would never have reached the place that it now claims to occupy. So it must ever be the duty of the clinical pathologist, I feel, to be alert to put to the practical test of experience those new methods and new theories that the physiologist develops, for often the latter has no real opportunity to put them to practical use.

In thus applying the physiologist's methods to the study of the patient, the clinical pathologist becomes a clinician. He may not, and should not, assume responsibility for the care of the patient, but as a diagnostician he should always feel a grave responsibility to the patient, for on his accurate observations depend the diagnosis of the disease and the plan of treatment, surgical or medical. His attitude toward his colleague should be that of a consultant. Although it may be sufficient merely to give a report of observations, the alert and conscientious clinical pathologist should be able to interpret those observations as applied to the particular case in hand. If his opinion is sound and his conclusions are accurate, he will command the respect of the surgeon or clinician who has sought his advice. Then, at times, he may be called on to extend his relationship to the patient by administering a form of treatment which has been developed in the laboratory and which is possibly best handled by the clinical pathologist, such as administration of vaccines and serums, intravenous injection of solutions, and possibly also performance of transfusions of blood.

As a research worker the clinical pathologist may not hope to compete with his brother who devotes his entire time to such alluring fields. However, his daily duties give him an opportunity always to carry on some investigation. He usually has animals and facilities at his disposal for some form of experimentation. The clinical material that he has at hand usually will provide him with an opportunity for more study than that which is merely necessary to make a diagnosis. In some one of the several fields of interest that I have mentioned, the observing clinical pathologist may often find, in his daily routine, something really worth the most careful study and recording in medical literature.

As I have mentioned, the clinical pathologist also has an opportunity to contribute to the knowledge of general medicine by trying new methods and properly evaluating with the clinician the data thus obtained. In this connection I should like to refer to an address of Arno B. Luckhardt, chairman of this section in 1923. He made "a plea for the concerted efforts of the clinician and the laboratory worker," and said: "The problems in clinical medicine awaiting a practical solution are numerous. In these problems the highly specialized laboratory man is not interested, chiefly because he has no knowledge of them. With a general medical background he would give these problems the attention now devoted to problems of a highly technical nature in his own specialty. Whereas some men seek knowledge for its own sake, others are urged to research because of the practical importance of the knowledge sought for, but in the last analysis, all knowledge is of practical importance, the only difference being that some knowledge is more immediately practical than other knowledge. The solution of more or less practical problems in no way interferes with the development of any science, but rather hastens its development." Dr. Luckhardt probably had in mind the relation of the physiologist to the clinician; nevertheless I feel that he suggested to the clinical pathologist a real opportunity.

Moreover, whether or not the modern clinical pathologist desires the responsibility, he usually finds that he must be an executive. As a director of a laboratory he must employ technicians, purchase supplies and apparatus, keep accurate records, and make charges for services rendered. He must be as much of a business man as a physician can be, and often many of the details of the hospital, institution, or group, will intimately dovetail with the actual business of running the clinical laboratories. In training his technicians he becomes a teacher, not often to be sure in a didactic way, but rather by example and by criticism and daily conference. He may even have the opportunity to do more. It is an acknowledged fact that there is a scarcity of clinical pathologists in the United States. Young men with a liking for laboratory work may take up this specialty if the opportunities can be made attractive. Three years' experience working under a clinical pathologist or in the closely allied fields is considered the minimal requirement for adequate training to fit one for an independent position in this field. Here, truly, the relationship between teacher and graduate student may become evident. The very future of this specialty depends on recognizing and assuming this duty.

Resentment toward a colleague whose manner toward the laboratory man may be irritating does not improve the situation in any way and need not be stressed. Modern medicine is now irrevocably dependent on laboratory methods for diagnosis, and the law of demand in relation to supply will inevitably work.

Some mention should be made of those teachers of the last twenty years who have deliberately espoused the cause of clinical pathology and who, by example and precept, have made the specialty what it is today. We all know and revere the names of Stitt, Todd, Emerson, Simon, Cummer and Webster and have turned to them and many others daily for information.

I realize that to many of you what I have tried to say seems trite. You are the clinical pathologists of today and know all of the problems as well as or better than I do. I might have dwelt more on the economic side of this specialty, but in describing the activities of the clinical pathologist as I see them, I cannot but feel that the outlook is bright. Diagnoses by laboratory methods are now accepted. Correlation of laboratory and clinical data must be made by a physician, not by a chemist, not by a technician. In assuming the rôle of the consulting physician on matters of laboratory diagnosis, the clinical pathologist will come into his own.

NEW PROBLEMS OF THE ORTHOPEDIC SURGEON *

C. B. FRANCISCO, M.D.
KANSAS CITY, MO.

The practice of medicine is undergoing a definite change. There are many indications of this, such as the appointment of the various committees for the study of the cost of hospital care, the cost of medical education and other inquiries that are being made under the direction of the American Medical Association. In addition to this, there are many lay organizations that are interested in the prevention and care of the sick and disabled. The result of this activity up to the present time is quite evident in that no one can deny that there is now better supervision of all medical and surgical work and that a noticeable advancement has been made in the prevention of disease. Just what the further and ultimate effect is going to be one cannot say, but that it is important for the profession to take a vital interest in the movement so that the progress will be along the proper lines is self-evident; to stand aloof and cry out that we are drifting into state medicine with its attending disaster to the principles and precedents of our profession is not the proper way to meet the issue that we face. If we use our efforts to guide the movement along proper lines it will no doubt work out for the common good of all concerned.

Orthopedics, the branch of medicine that this section represents, is probably undergoing a greater change than any other branch of medicine. The greatest movement in the interest of the crippled child that has ever been known is sweeping over the whole country. It is interesting and important to note what the tendency of this movement is. Observations rather clearly indicate that the tendency is to take the work to the communities rather than to take the child to the centers where the work has been established. Many of the states in the central portion of the country are at work on plans that will establish clinics throughout the state both for the operative and for the follow-up care of these cases. This is, no doubt, the result of the success that has followed the establishment of hospitals in these various communities for the care and treatment of general conditions. If this plan is proper and is to be the one

---

* Chairman's address, read before the Section on Orthopedic Surgery at the Eighty-First Annual Session of the American Medical Association, Detroit, June 27, 1930.

ultimately worked out, it creates a definite responsibility in the teaching of orthopedics in the medical schools.

To meet this demand, medical students and interns will need to be taught more of the principles of orthopedics and that it is definitely a part of medicine and surgery and not a distinct specialty. It would also necessitate standardizing the ordinary procedures in this line of work and removing the mysterious atmosphere that at present hovers around this specialty. Many physicians are often embarrassed by being referred to as miracle workers when in reality there is nothing about the correction of deformities that is any different in principle from surgical work in general. The aims are exactly the same; namely, to overcome the effects of disease and disability and to restore the patient to usefulness.

That students can be taught to care for the ordinary congenital and acquired deformities is, to my mind, just as logical as the fact that they can be taught to care for the ordinary ailments that they are expected to care for in the general practice of medicine. It is true that they need supervision in a general way and that it will always be the function of the medical centers and of the medical organizations to furnish this supervision and to supply the institutions to care for the unusual cases that will always exist. Medicine and general surgery have only recently been established on the community basis, and it has worked out so successfully that my observations lead me to believe that the trend of orthopedics is toward a similar plan; to my mind it is possible to work it out in time quite satisfactorily.

The other phase of orthopedics has been toward the industrial side of medicine. This is a tremendously large field and one that is rapidly undergoing reorganization. Compensation laws and insurance organizations are assuming control with a tendency to direct this work. They are requiring more from the industrial surgeon than the surgeon has ever produced. They are demanding shorter hospitalization periods, a quicker return to duty and earlier adjustments of claims. This is also greatly to the advantage of the claimant. The best possible method of preventing compensationitis is prompt action by the physician in recommending a hearing before the compensation board. The insurance companies need the guidance of the medical profession but they are still casting about for the methods that bring the quickest results.

The orthopedic men have been the ones to whom they have turned for advice. At the present time they are looking to us to reorganize and supervise the care of cases of industrial injury. There is much that we must consider if we are to direct industrial surgery successfully. One of the important phases is that of medical ethics. Insurance companies know nothing about medical ethics and, in reality, care nothing about them. To allow our established principles of ethics to be broken down would mean ultimate disaster for us as well as for them. We must therefore labor with these organizations until they are willing to accept our established code; also, we must labor with ourselves so that we can see and are willing to accept the insurance company's point of view. We should also understand that compensation laws cannot possibly be framed to the end that justice can be secured for every individual, and also we should understand that the individual will be best served by the fair and just rating of all cases. Therefore, the work of supervising and placing this field of medicine on its proper basis is of vast proportions and I would like to urge that each member of this section renew his allegiance to this branch of orthopedic surgery that has literally been thrust on us to the end that we prove ourselves equal to the task of properly directing the organization of this branch of surgery to the satisfaction of all.

306 East Twelfth Street.

THE HEART IN PREGNANCY *

WILLIAM D. REID, M.D.
BOSTON

What advice shall be given to the cardiac patient who contemplates marriage? If pregnancy ensues is it not likely to cause the mother's death or, if not that, to cut years off her length of life? It is my purpose in this article to discuss pregnancy in the cardiac patient in an attempt to answer these questions and to offer a brief statement of the therapeutic principles.

DIAGNOSIS

The first essential is an accurate diagnosis of the condition of the heart; it has been amply demonstrated that many of the patients whose hearts have been thought to be diseased in reality possess fully normal hearts. Gammeltoft[1] of Copenhagen has shown that during pregnancy the cardiac condition may often simulate organic disease although the latter is not actually present. He studied 239 perfectly healthy pregnant women and found that during the final two months of pregnancy 39, or 16.3 per cent, showed signs that suggested organic cardiac disease. These were: rapid pulse, extrasystoles, visible venous pulsation, and systolic and diastolic murmurs at the base of the heart and over the pulmonic and tricuspid valves. In no instance could these be detected four weeks after parturition. Gammeltoft writes: "I do not doubt that quite a number of cases of functional heart disturbances are included among the cases of heart disease which are treated in obstetric clinics everywhere. This in turn means that statistics will vary a good deal."

It may be well to give a definition of heart disease. In simple language this can be stated as some structural change that can be detected macroscopically or at least microscopically by the pathologist at postmortem examination. I am not concerned, for the purpose of this article, with the belief of some authors that there may be instances of cardiac disease in which the abnormality is due to physicochemical changes that are as yet undetectable by the present methods of examination.

There are certain guides or principles that should be more generally followed before deciding that organic heart disease is present:

The Rule of Age: The diagnosis of heart disease in patients under 40 years of age is rarely justifiable in the absence of one or more of the chief reliable signs; in the elderly the reverse is true. Most pregnant women are less than 40 years of age.

The chief reliable signs of organic heart disease are:[2]

1. Distinct overdistention of the veins of the neck.
2. A precordial thrill, if a definite "purr"; a slight vibration is insufficient.

---

* *From Boston University School of Medicine, and the Evans Memorial.*

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

[1] Gammeltoft, S. A.: The Heart in Pregnancy, Surg. Gynec. Obst. **46**: 382 (March) 1928.

[2] Reid, W. D.: Cardinal Principles of Cardiac Diagnosis, Boston M. & S. J. **197**: *132 (July 28)* 1927.

3. An unmistakable pericardial friction rub.
4. A diastolic murmur.
5. An irregular rhythm, persisting after exercise, especially if the rate is or reaches 120 or higher.
6. Definite signs of enlargement of the heart.
7. Expansile pulsation of the liver.
8. Widespread arterial disease or a persistent blood pressure of 160 or above in a young person, of 180 or higher in the elderly.

It should be remembered that in pregnancy signs 1 and 6 must be used with caution. The increase in abdominal pressure during the later months of pregnancy causes distention of the cervical veins; this disappears promptly after delivery. Also, when the uterus is large its tendency is to cause a high position of the diaphragm which in turn produces a more transverse position of the heart. In this way the location of the cardiac impulse and borders of percussion dulness are displaced outward, and the unwary may believe that the heart is enlarged. The enlargement is apparent but not real; if the size of the heart is to be accurately determined, resort to roentgen mensuration should be made. And, furthermore, there are occasional instances in which the sign described under item 5, i. e., auricular fibrillation, occurs in an otherwise normal heart.[3] Gammeltoft [2] has been cited as having detected diastolic murmurs in some pregnant women whose hearts were normal. It is noted that he did not find these apparently functional diastolic murmurs at the apex. Therefore, the middiastolic murmur of mitral stenosis retains its reliability as a sign of that lesion. The occasional exceptions to the foregoing reliable signs have been discussed elsewhere.

Minimal Symptoms and Signs: A diagnosis of cardiac disease is indicated at times in spite of the lack of any of these reliable signs. This applies to angina pectoris, certain electrocardiograms, bacterial heart disease and, in elderly patients, a diminution in the tolerance for exercise. In young persons in the absence of one of four cardiac conditions—definite enlargement, aortic disease, mitral stenosis, or auricular fibrillation—a deficient exercise tolerance should rarely be attributed to the heart; tuberculosis or other infection is more likely. Pregnancy itself causes a lessening of the tolerance for exercise.

Practically all cardiac symptoms and signs not listed here, though often associated with organic disease of the heart, are so frequently present with the normal organ that they are not of themselves reliable evidence of cardiac disease.

TYPE OF HEART DISEASE

In patients in whom the results of examination justify the diagnosis of organic heart disease, rheumatic heart disease is the type nearly always present. In fact, other observers [4] have found that more than 90 per cent of the cases of significant heart disease in pregnancy are those of the rheumatic type; my experience agrees with this figure. Because of this fact the subject matter of this article will be limited to rheumatic heart disease, or, as it is less well termed, valvular disease of the heart.

STATISTICS ON RHEUMATIC HEART DISEASE

There are not available many statistics as to the age of death of patients with the rheumatic type of heart disease. In table 1 are given such as I have been able to find. The average age at death of the patients studied in these reports is 35.5 years.

For the purpose of obtaining data relating to the age at death of the patient affected by rheumatic heart disease and its relation to pregnancy, I have searched the postmortem records of the Boston City Hospital from 1916 through 1928, a period of twelve and a half years. Some of the pertinent data are presented in table 2.

TABLE 1.—*Mortality from Rheumatic Heart Disease*

Authors	Cases, Number	Males, Number	Females, Number	Age at Death, Years	Duration from First Attack of Rheumatic Fever to Death, Years	Age at Death	
						Males, Years	Females, Years,
Willius, F. A.: Am. Heart J. **3**: 139 (Dec.) 1927	160	80	80	39.5	14	41	38
Cohn, A. E.: Am. Heart J. **2**: 275 (Feb.) 1927	...	..	..	20-35* 35-45*	 15*		
Cabot, R. C.: Facts of the Heart, Philadelphia, 1926	107	45	62	30-39	..	60% before 40	40% before 40
Coombs, C. F.: Rheumatic Heart Disease, New York 1924	98	..	..	28.2			
Reid, W. D.	27	7	20	43	28†	38.6	43
Average................	..	..	..	35.5‡	..	40.8§	39.0§

* Computed from the literature.
† Average for 12 of the 27 cases.
‡ Cohn's figures were not used in obtaining this average age.
§ Computed from Willius and Reid only, so the average is not actually comparable with that of the entire group, as given in the fourth column.

TABLE 2.—*Sex and Marital State in Necropsy Cases*

	Cases, Number	Age at Death, Years	Average Size of Mitral Orifice, Cm.	Cause of Death	
				Cardiac, Number	Other Disease, Number
Entire group..............	27	43.2	5.9	13	14
Males......................	7	38.6	5.0	3	4
Females....................	20	44.8	6.1	10	10
Single..................	10	47.2	6.5	5	5
Married.................	10	42.4	5.8	5	5

The study was limited to instances of definite stenosis of the mitral valve. It was felt that statistics based on the presence of this lesion could not be questioned, as it appears to be generally accepted that mitral stenosis is caused solely by rheumatic heart disease; only cases proved post mortem were utilized in order to eliminate the possibility of errors in the clinical diagnosis and the rare occurrence of narrowing of the mitral valve by nonrheumatic lesions.

The possible criticism that the statistics may be affected by the noninclusion of mitral insufficiency and aortic lesions is answered by pointing out that other observers [5] have found that analysis of their cases in relation to the valvular lesions present showed that the particular valve lesion had little determining influence on the mortality rate.

There were found only twenty-seven cases of rheumatic mitral stenosis; nevertheless it is believed that the statistics obtained from this group offer information on the subject in hand, namely, the heart in pregnancy. The reader is cautioned against giving these figures unwarranted significance. Their number, as already stated, is small and they are limited to the most definite cases. The group is a representative one, rather than a complete group of the lesions of the rheumatic type of heart disease. It is also appreciated that they are drawn from but a single source, that of a large metropolitan hospital. I was not seeking information about rheumatic heart disease in general but the effect of pregnancy on such hearts. Subject to the foregoing, and doubtless other limitations, I consider the statistics to be of value.

[5] Pardee, H. E. B.: Pregnancy Complicating Heart Disease, Am. J. M. Sc. **164**: 847 (Dec.) 1922. Footnote 4, first reference.

The average age at death of these twenty-seven patients was 43.2 years, while that of the single women was 47.2 years and 42.4 years for those that were married. In but twelve of the group was it possible to determine the duration in years of the disease, when the latter was estimated from the initial attack of rheumatic fever or chorea. This is not surprising when one recalls that in approximately half the cases rheumatic heart disease is present in the absence of a history of an etiologic infection. The figures on duration are not of much significance as they are subject to too considerable error; one can, however, place more reliance on the age at death. The cause of death was the disease of the heart in but half of the entire group; on this point there was no significant difference in relation to sex or marital state.

The figures gleaned from the ten married women are of greatest interest. In one case there is no statement as regards the bearing of children; in a second, the clinical record mentions repeatedly that the patient was the mother of "a large family" but does not specifically state the number of offspring. The remaining eight women bore children, 46 in all, or 5.75 children per mother. There was but a single miscarriage. The latter occurred in a woman who had successfully borne five children but who aborted in her sixth pregnancy. The fetus was lost at five months during a febrile disease from which she died five months later and which was proved to be subacute bacterial heart disease; *Streptococcus viridans* was present in the blood cultures both in life and at the necropsy. This single miscarriage can probably be attributed to the terminal viridans infection rather than to the rheumatic heart disease.

It is reasonable to assume that if pregnancy was a potent cause of the premature death of women with heart disease some evidence of this effect would be shown in the records of patients in a large hospital such as the Boston City Hospital. My search, however, has disclosed no essential difference save an average age at death of 4.8 years less for the married women than for the single, but even then the former outlived the men with the same cardiac disease. When the data are analyzed in relation to the number of children and miscarriages, the figures appear even more favorable. I feel safe in concluding that as far as these statistics have value they support my clinical impression that women with rheumatic heart diseases die before their time, in fact during the child-bearing period, not because of marriage and pregnancy but on account of the natural evolution of this disease.

EFFECT OF PREGNANCY ON THE HEART

It has been shown[6] that the blood volume is increased in pregnancy. Barcroft[7] has discovered in addition that a contraction of the spleen occurs in pregnancy. The increase in the blood volume takes place at about the middle of gestation or at the same time as the observed contraction of the spleen. It is considered, therefore, that the increase in the volume of the blood is derived from that released from the large content in the spleen before it contracts.

One of these investigators[8] has shown that in pregnancy the volume output per minute of the heart is increased an average of 44 per cent and he concludes therefore that to accomplish this the work of the heart has increased to the same extent. However, the late Sir James Mackenzie[9] emphatically stated that there is no such thing as heart disease caused by pregnancy. He believed that pregnancy did not induce cardiac hypertrophy or any pathologic change in this organ.

There are certain facts in the physiology pertaining to the heart that cause one to question whether it is correct to infer, as I understand Haupt to do, that an increase in the output of the heart per minute indicates a corresponding percentage of rise in the work of this organ. As pregnancy advances the progressively enlarging uterus gradually distends the abdomen with increased intra-abdominal pressure, and thereby better return of the venous blood to the heart ensues. The effect of this is stated by a physiologist[10] as follows:

> By increasing the venous return the output per beat is increased proportionately. The greater *initial length* of the cardiac fibers at the beginning of systole results in more forcible contraction, so that greater amounts of blood are discharged at each beat ("Law of the Heart"—Starling). If the fibers are overstretched, then a more feeble contraction results, the output is diminished, and the heart does not empty itself effectively. The pressure in the heart rises very little during the diastolic filling, because the heart fibers elongate and adapt themselves to accommodate the blood which is entering.

According to Starling's law of the heart, just mentioned, within certain limits of augmented return of the venous blood the myocardium contracts to better advantage, and the output of the heart increases more than the actual work of the muscle. The physiology of the circulation is complex and this is not the place to attempt its further discussion.

It might be thought that the death of some of these patients within the first year or two after the birth of a child was due to an effect of the pregnancy in reactivating the rheumatic infection in the heart. The analogy of tuberculosis is cited. This analogy has, however, lost much weight with me since I have been informed that an analysis undertaken in Vienna[11] of 8,000 pregnancies disclosed that inactive tuberculosis rarely becomes worse through pregnancy: only 5 per cent of the patients showed lighting up of the tuberculous process and these cases were thought probably to have been active before the onset of pregnancy. Some patients have trouble in one pregnancy and little if any in a subsequent one.[12] Perhaps this difference is in part due to activity of the rheumatic infection during the particular pregnancy in which cardiac insufficiency was present.

It is true, nevertheless, that cardiac insufficiency appears in a considerable number of these patients during pregnancy and appropriate therapy is imperative.

The prognosis is often uncertain; it is not easy to predict in many cases what degree of disturbance, if any, may ensue.

PROGNOSIS AND TREATMENT

Medical literature contains numerous good articles on the treatment of the cardiac patient who is pregnant. I will therefore touch but briefly on this aspect of the subject. Table 3 gives the mortality in about 40,000 deliveries in three maternity hospitals.[13]

TABLE 3.—*Mortality in Three Hospitals, 1922-1927* *

	Boston	New York	Robinson	Totals
Deliveries	8,410	21,597	9,759	39,766
	109	197	96	402
	1.29%	0.91%	0.98%	0.98%
	21	15	3	39
deaths from all causes........	19.2%	7.6%	3.1%	9.7%

* The statistics are from the Boston Lying-In Hospital, the New York Lying-In Hospital, and the Robinson Memorial, Boston.

The prognosis and treatment of these patients is dependent on the presence or absence of cardiac insufficiency rather than on the structural change in the heart. The severity of the cardiac insufficiency, if present, is important. The time in pregnancy that congestive failure has occurred and the response to adequate therapy are significant factors. Severe cardiac insufficiency is usually preventable in patients under proper observation for, if therapy is not successful, operative intervention should be used before the patient is in a grave state.

In some patients the abrupt onset of a cardiac arrhythmia induces congestive failure of the circulation by forcing the heart to beat at an unduly rapid rate. The specific arrhythmias are paroxysmal tachycardia, auricular flutter and auricular fibrillation. In these cases it is clearly desirable to postpone emptying the uterus until the state of the circulation has improved through cardiac therapy. Skilful use of the well known methods of stimulation of the vagus nerve will often terminate paroxysmal tachycardia, and in those cases in which it fails the rapid administration of digitalis will reduce the ventricular rate to a more normal level. This may be accomplished within a few hours and permit the operative intervention under more favorable conditions, or, if the patient's condition warrants, it may be decided to maintain the cardiac improvement by further digitalis and let the pregnancy continue.

The principles applicable to the decision as to whether or not the pregnancy should be terminated are relatively simple. Evidence of activity of the infection of the heart or of insufficiency of that organ, if it does not promptly yield to treatment, is an indication for operative intervention. In the occasional case in which the heart disease is complicated by disease in other organs (nephritis or active tuberculosis), pregnancy should be terminated.

In the instances of acute pulmonary edema during labor the condition should be met by the hypodermic administration of morphine sulphate, ¼ grain (16 mg.), atropine sulphate, $\frac{1}{50}$ grain (1.3 mg.), and digitalis intravenously in adequate dosage. This therapy should be continued according to need. If labor ceases because of the effect of the morphine, so much the better. The patient's condition may improve sufficiently during the short respite to permit parturition to be resumed under more favorable conditions. This is similar to the abrupt onset of a cardiac arrhythmia, already mentioned, which may or may not be associated with the acute pulmonary edema.

No attempt to induce labor or empty the uterus should, of course, be made in a patient in whom cardiac insufficiency of severe degree is present. It is far safer to keep such patients quietly in bed and resort to medical therapy (morphine and cardiac drugs) than to subject them to the added strain of an operation. If such patients will not survive medical measures, it is unlikely that they will tolerate the shock attending an emptying of the uterus. The problem is not identical with that of the toxemias in which the contents of the uterus are believed to be an important factor in causing the toxemic state. Unless labor is already present, the seriously ill cardiac patient should not be disturbed until her condition has improved.

The method of operative intervention to be employed should be left to the obstetrician; the cardiologist may well be content with stating merely that the procedure attended by the least strain to the mother should be selected. It is obvious that the number of the pregnancy, the record of the patient in former deliveries, the position of the fetus and the relation of its size to that of the maternal pelvis are of importance in deciding on the method of interrupting the pregnancy. If the obstetrician has particular skill in a certain operative procedure, this fact may turn the choice to that particular method.

The services of a skilled anesthetist are more important than the choice of a particular anesthetic. In fact, the selection of the latter may then confidently be left to the anesthetist. A general anesthetic such as ether has no damaging effect on the heart.[14]

It will be noted that I have barely mentioned the details of the medical treatment of cardiac insufficiency in pregnant women. They do not differ essentially from those practiced in nonpregnant patients and consist, of course, mainly in the adequate use of digitalis and rest. Experience shows that rest in bed for more than a short time is not essential to patients in whom the symptoms of cardiac insufficiency are not severe and are promptly relieved by therapy.

The obstetrician must have a good knowledge of cardiology or seek the assistance of a heart specialist when one is available. The treatment of the cardiac patient who is pregnant, to be most successful, requires the cooperation of both cardiologist and obstetrician.

COMMENT

There is clearly a need for the gathering of statistics pertaining to the longevity of persons with rheumatic heart disease in relation to the marital state and number of offspring.

It has been found that the average mortality of cardiac disease in pregnancy ranges from 5 to 10 per cent,[13] whereas the average annual death rate from rheumatic heart disease for patients of both sexes aged 20 to 40 years is estimated[15] to be about 3.5 per cent. The difference, then, between the two, 1.5 to 6.5 per cent, gives a suggestion of the amount of increase in the mortality of cardiac patients due to pregnancy and parturition. In view of the gloomy opinion expressed by some writers it may be well to turn the figures about; one finds, then, that 90 per cent or more of women with heart disease survive pregnancy.

[15] Cohn, A. E.: Heart Disease from the Point of View of the Public Health, Am. Heart J. **2**: 275 (Feb.) 1927; my calculation from figures found on p. 277.

If it is true that these women with organic heart disease are dying during the child-bearing age because of the natural evolution of rheumatic heart disease and not because of pregnancy, it seems reasonable that this fact should be given consideration when these patients seek advice with regard to marriage and pregnancy. It has been well said by Hay and Hunt that motherhood is woman's peculiar privilege and prerogative, a privilege which one has no right to refuse without adequate reason.

The status of the unmarried woman with heart disease is much closer than is usually taught, I believe, to that of the male cardiac patient who is contemplating marriage. The prospective mother has the problem of whether she can adequately care for her future children. There also is the possibility of the early death of the patient (male or female), causing the leaving of dependent children. The amount of damage which the heart has already suffered, and the financial, social and intellectual status of the patient, have much importance in the decision reached. This is obviously a radically different approach to the subject of marriage in patients with organic heart disease than that which holds childbearing prohibited in all cardiac patients.

SUMMARY

The first essential is an accurate diagnosis of the condition of the heart. Organic disease of the heart is absent in many pregnant women the integrity of whose hearts has been questioned.

If cardiac disease is present, it is nearly always some form of rheumatic heart disease.

The average age at death of patients with rheumatic heart disease is 35.5 years.

Statistics show that the average age at death was 42.4 years for married women with heart disease and 47.2 years for those that were unmarried. The number of children of the married women in the group analyzed averaged 5.75.

The mortality from cardiac disease in pregnancy is but slightly greater than that of cardiac patients of similar age in the general population. Probably 90 per cent or more of cardiac patients survive pregnancy and parturition.

CONCLUSIONS

Married women with rheumatic heart disease die before their time because of the natural evolution of this disease rather than because of child-bearing.

This fact should be given consideration when advising women with heart disease regarding marriage and pregnancy.

510 Commonwealth Avenue.

Fear is a Mental Deformity.—The behavior problems of David—hitting children, destroying their projects, and acting silly—are not unknown among two-year-old children in the "best families." There the usual treatment is a sharp command to "stop that" or, perhaps, physical punishment. Both of these methods are unpsychological because each maims the personality. Neither one develops the child. So far as either has any effect, the restraining influence is fear; and fear is a mental deformity. The behavior of many mothers would seem to indicate that they think their chief function is to thwart or forbid, and to enforce their prohibitions with punishment which is thought suitable to the tender years of the child. This is the easiest way to discipline. It is also the worst.—Swift, E. J.: The Psychology of Childhood, New York, D. Appleton & Co., 1930.

CARDIOVASCULAR DISTURBANCES IN THE OBSTETRIC PATIENT

WITH ESPECIAL REFERENCE TO ELECTROCARDIOGRAPHIC OBSERVATIONS *

GEORGE HERRMANN, M.D.
AND
E. L. KING, M.D.
NEW ORLEANS

The relative infrequency of the problems of heart disease in the individual practitioner's obstetric experience has led to a somewhat passive attitude on the part of too many physicians toward the subject. It must be admitted that most of the larger series of gravidocardiac patients reported have come from institutions into which for the most part only complicated cases are admitted. Those working in such institutions are perhaps prone to acquire an exaggerated idea of the importance of the subject. Nevertheless, on the facts gleaned from these extensive studies are formulated the rules to be relied on for guidance in the rational scientific management of the isolated case.

Pregnancy in a patient with heart disease has long been recognized as a seriously complicated situation. Jardine [1] was impressed by the disastrous results accompanying the induction of labor in the gravidocardiac patient. Williamson [2] reported similar conclusions as to the exceedingly great risk in the danger of collapse and sudden death of pregnant women with heart disease after delivery following the introduction of bougies. Mackenzie,[3] Pardee,[4] Wilson and Herrmann,[5] Robinson,[6] Oliver,[7] Hay and Hunt,[8] Jensen,[9] Zinsstag,[10] von Jaschke,[11] and especially Lennie [12] in England, Sachs [13] in Germany and Hamilton and Kellogg [14] in this country, have reported extensive and important clinical studies.

CRITERIA

In any study such as this, it is desirable to state clearly our conception of what the general term "heart disease" embraces. We have considered as patients with heart disease only those who present the reliable criteria or physical signs [15] as evidence that the heart muscle has suffered impairment of its reserve through the effect of infection, allergy, anoxemia, strain, exhaustion, undernutrition or developmental disturbances. The state of the heart muscle is such that sooner or later the symptoms and signs of myocardial insufficiency, namely, congestive or anginal heart failure, will appear. This "decompensation" is the result of such precipitating factors as undue exertion, intercurrent toxemia, lack of oxygen or the inevitable vascular and circulatory changes and complications of advancing cardiac hypertrophy and age, and the inevitable embarrassment of the coronary circulation.

[15] Besides diastolic mitral and aortic thrills and murmurs, evidences of rheumatic or syphilitic heart disease, there are these other individually pathognomonic signs of heart disease, as engorged neck veins, cardiac enlargement, heart block, auricular *fibrillation* or *flutter* or *pulsus alternans*, aortic dilatation or aneurysm, widespread general arteriosclerosis, chronic hypertension or evidences of chronic nephritis *or chronic* hyperthyroidism, angina pectoris and none other. The presence of any one of these diagnosticates *the presence* of heart disease *and the* absence of every one of them may be taken as proof that the *patient is not suffering* from heart disease.

MATERIAL

We have been engaged in accumulating these data in the heart station and in the prenatal clinic and maternity service of the Charity Hospital of New Orleans during the past three years, 1927, 1928 and 1929. Within this period there have been admitted a total of 24 cases (1.38 per cent) of heart disease among 1,746 pregnant white women, of which 16 patients (0.916 per cent) with serious cardiac valvular disease with and without disturbances of mechanism complicating the pregnancy were found. At the same time there were also 8 cases (0.458 per cent) with toxic or other myocardial damage and congestive failure. Hypertension, toxic nephritis or eclamptic states were present in 47 cases. The mortality figures were as follows: heart disease, 8; eclampsia, 10; other toxemias, 3; collapse, 4; placenta praevia, 5; premature separation of placenta, 1; postpartum hemorrhage, 2; septicemia, 4; pneumonia, 2; full term abdominal pregnancy and parturition, 1; miscellaneous conditions, 8; total, 48.

The series, though not an extensive one, has been exhaustively studied electrocardiographically as well as clinically, and has yielded information on some of the less stressed but nevertheless important points in the problem of heart disease and pregnancy. We have been especially interested in the disturbances of cardiac mechanism often found in patients with more or less serious chronic cardiac valvular disease. We wish, furthermore, to call attention to significant types of cardiac failure in patients with nonvalvular heart disease and serious partum complications.. We have considered as gravidocardiac only those patients who presented one or more of the accepted physical evidences of heart muscle damage.

GROUPS OF GRAVIDOCARDIAC PATIENTS

We have divided our cases into five groups, in each of which there are several patients. The patients with signs of complicating disturbances of cardiac mechanism corroborated by electrocardiographic observations are collected and presented in the first group as a means of calling especial attention to this type of case. There are, as usual, along with these disturbances of mechanism also the evidences of precipitating or concomitant chronic rheumatic valvular defects. In all the other cases the electrocardiographic changes when reflecting the effects of valvular changes only were not commented on.

The groups and their make-ups are as follows:

Group 1.—*Gravid patients with disturbances of cardiac mechanism, electrocardiographically recorded, as added complications to the more or less severe rheumatic heart disease.*

In this group we have had two patients with complete bundle branch block. One of these, a multipara, aged 33, also had mitral stenosis and insufficiency, aortic regurgitation and slight stenosis as well as anginal and congestive heart failure. She and her seventh baby died during the spontaneous delivery. The second, a primipara, aged 37, with complete bundle branch block, had an acute rheumatic pancarditis that was discovered in the second month and subsided under treatment, leaving valvular damage and intermittent bundle branch block. During one of the periods of intermittence the patient was successfully delivered of a living baby by cesarean section, and during another an operation for sterilization was accomplished. These most unusual and interesting types of serious cardiac mechanism disturbances have not, so far as we know, been described hitherto in the pregnant woman.

Bundle branch block, as we have pointed out, is a considerably more serious complication and increases the risk in obstetric and also in surgical cases more than does auriculoventricular block. As evidence of the seriousness of intraventricular conduction defects stands witness the fact that our first patient, a multipara who was allowed to go into labor, died suddenly in the beginning of the second stage. We have records of two patients with similar disturbances who died suddenly at the beginning of the surgical procedures. The second patient with bundle branch block was fortunately found by repeated electrocardiographic studies to have short periods of normal conduction after complete rest for a few days. She was followed from the second month to the eighth month at regular intervals of a few days and then daily until it was found after a considerable rest that she was out of block. A cesarean section was performed in one period of normal conduction and in another interval sterilization was accomplished. Bundle branch block returned, but the patient and the baby survived and have been unexpectedly well.

A third patient in this group had had complete auriculoventricular heart block since the age of 20 and had six successful deliveries without any complications. Her valvular damage had been slight with only evidence of mitral insufficiency. This instance of another significant type of unusual disturbance of cardiac mechanism, complete auriculoventricular heart block of long standing with little or no other cardiac damage, seemingly had no disturbing effect. The latter patient had not had a heart rate above 40 since her slow pulse was noted at the age of 19, but no trouble had been experienced in her six parturitions.

A fourth patient presented auricular fibrillation as well as high grade mitral stenosis and congestive heart failure. She and her baby both died during premature labor in the eighth month of her sixth pregnancy. The fifth patient, with paroxysmal auricular tachycardia and rheumatic mitral insufficiency, delivered her ninth baby without any difficulty. Other cases of this disturbance have been likewise handled without difficulty. The sixth patient, with premature contractions, rheumatic mitral insufficiency and stenosis and congestive heart failure, was rested and digitalized and uneventfully delivered her sixth living child.

Auricular fibrillation is a relatively rare obstetric but serious complication under any circumstances, always indicating advanced concomitant myocardial damage. Less serious types of cardiac mechanism disturbance such as paroxysmal tachycardia and premature contractions often occur in gravid patients with normal hearts and are of little consequence if correctly diagnosed and interpreted.

Group 2.—*Gravid patients with chronic valvular heart disease without disturbances of rhythm.*

In this group practically all the patients had high grade mitral stenosis and insufficiency. In two patients there was congestive heart failure in the middle months of the seventh and eighth pregnancies. One was successfully treated and tided along until the seventh month, when she was delivered of a living baby by cesarean section. The other disregarded advice and orders, did not respond to her second digitalization and rest,and succumbed to pulmonary edema following the cesarean delivery of a living baby under ether anesthesia. Four other mitral stenosis patients with mild grades of congestive failure were all successfully treated and delivered spontaneously without any mishap. One patient with mitral stenosis and pulmonary cirrhosis died undelivered. Two patients with aortic regurgitation, with and without mitral disease, had little difficulty after a short period of digitalization and rest in bed preceding confinement.

Two patients with congenitally defective intraventricular septum and slight conus stenosis with and without patent ductus arteriosus and cyanosis, both without congestive failure, have been observed to go through pregnancy and labor without any difficulty.

Group 3.—*Gravid patients presenting besides chronic valvular defects also acute and subacute postpartum exacerbations of previous rheumatic infection and cardiac damage.*

One of the patients in this group began to have acute inflammatory manifestations in the fourth month of her first pregnancy but was tided along on salicylates and digitalis until the seventh month, when she delivered a premature baby that survived. This was her first pregnancy, and sterilization was advised because of the evidences of chronic rheumatic, mitral and aortic and myocardial disease. The other had an exacerbation of her rheumatic disease beginning in the later months of her first pregnancy and continuing for three months post partum. She recovered under salicylate therapy. Because of the chronic rheumatic mitral disease, she was advised against further pregnancies. The second bundle branch block case of group 1 would also come under this heading.

Group 4.—*Gravid patients with myocardial insufficiency before and during labor and often presenting extensive pulmonary thrombosis as a result of chronic congestion of the lungs and further acute parturient slowing of the movement of the blood mass.*

In this group there were four patients recorded, in one of whom myocardial insufficiency of unknown origin appeared in the seventh month of her first pregnancy. Acute severe and persistent hemoptysis was accompanied by signs of consolidation of the lung bases. A postpartum pulmonary thrombosis was demonstrated at autopsy two weeks after the delivery of a dead baby. Another patient with a similar symptom complex with similar signs slowly recovered but had much difficulty because of myocardial and renal damage. A third case of the same type was discovered at autopsy to have pulmonary vascular damage which was erroneously considered extensive embolism. Still another, with a similar clinical picture, died, but permission for autopsy was refused. In this group might be included several patients with evidences of some renal damage that seemingly predominated the picture before delivery, except for some evidences of cardiac damage such as dilatation and an unusually conspicuous gallop rhythm. After delivery these patients usually persistently had rather high grade myocardial insufficiency. This group merges with the last group in which at times are placed cases that cannot be clearly differentiated.

Group 5.—*Gravid patients with acute toxic degenerative cardiorenal states, subacute and chronic nephritis, hypertensive, syphilitic aortitis or arteriosclerotic heart disease with ultimate circulatory failure.*

No instances of chronic hyperthyroid heart disease and pregnancy were encountered in this study.

Four examples of various combinations of these toxic degenerative disturbances in pregnant women have been selected for this report. In only one of these was a living baby delivered. One of the patients died; two became chronic cardiac invalids. The fourth one with paroxysmal attacks of acute cardiac failure survived. One patient with syphilitic aortitis and angina pectoris delivered a premature macerated syphilitic fetus and recovered.

The toxic cardiorenal group of gravidocardiac patients should probably be made up of various cases that present acute eclampsia, hypertension, chronic nephritis and arteriosclerotic heart disease that may or may not be accompanied by edema and engorged organs. A toxic renal state is quite often preliminary to heart muscle damage. Sometimes these patients present the signs of renal insufficiency at delivery only to change to the signs of myocardial insufficiency post partum.

COMMENT

In summarizing the groups it is apparent that the electrocardiographic studies have yielded important information that has not been previously emphasized in the obstetric literature. Auriculoventricular and bundle branch block and other disturbances of mechanism are thus found to occur in the pregnant woman and to affect profoundly the prognosis and require specific treatment in many cases. Normal pregnancy, as we [5] and others have shown, produces no significant changes in the electrocardiogram. The presence of defective auriculoventricular and intraventricular conduction or bundle branch block in the gravid patient apparently warrants clinical respect. Indisputable evidence of this defect is unfortunately revealed only by an electrocardiographic study.

Acute active endocarditis, most probably of the rheumatic type, has been present in two of our patients. Pulmonary thrombosis from stasis and pulmonary congestion, the result of myocardial insufficiency, is another serious type of heart failure that has been previously little if at all mentioned, and is here noted as a complication of pregnancy. We have had four such cases, of which two came to autopsy and two were diagnosed clinically only. One of the patients who survived presented definite evidence of having suffered from a pulmonary vascular accident a thrombosis as proved by hemoptysis and lung signs.

Chronic cardiac valvular disease in pregnant women makes up a large part of the series that we have studied. Fourteen of our cases presented definite evidences of some one of the valvular disturbances, the presence of which indicated concomitant myocardial damage usually with, rarely without, congestive failure.

The types of heart disease encountered in pregnant women are no different from those found in the general population, and the incidence is about the same. Heart disease in pregnant women may be in order, toxic, nephritic, hypertensive, rarely arteriosclerotic in type, rheumatic, syphilitic and goitrous. Disturbances of the cardiac mechanism may occur during pregnancy as well as at any other time. The significance of each of the various types is about the same as it is under ordinary conditions, but even the relatively numerous abnormalities may complicate matters. Only a few are of serious moment, but each must be independently evaluated, taking into account the other cardiac changes. Some arrhythmias, such as premature contractions, even in paroxysms, are of little significance but may embarrass the cardiac function when it is on a strain, as during labor. Auriculoventricular block, auricular flutter, fibrillation and alteration are serious, and especially so is bundle branch block.

The majority of gravidocardiac patients with serious heart disease—only about 25 per cent of all, but about 75 per cent of those that die—present a rheumatic mitral stenosis as the chief abnormality. Three fourths of the cardiac fatalities in pregnancy therefore are the result directly or indirectly of mitral stenosis, fibrous obstructive narrowing of the mitral valve. Therefore, the mechanical effects of the lesion must be a directly contributing factor. Criteria for the diagnosis of mitral stenosis should be reviewed since this lesion is of such importance. These signs have been described in detail elsewhere.[16] The lesion is perhaps the most often undiagnosed of all valve lesions. The characteristic sign is an apical diastolic, low rumbling sound rather than the higher pitched, blowing adventitious sounds usually thought of as murmurs. The rheumatic heart, as a general thing, is no more common in pregnant women than in the population at large.

From 1.5 to 2 per cent of pregnant women have cardiovascular disease. The number of these that have later complications is rather small. Only about 1 or 2 per cent have any trouble whatever during their pregnancy or even during the later great effort of labor. Yet 25 per cent of maternal deaths are due to the presence of a complicating heart disease. The physical strain of the muscular contraction necessary in labor is, of course, the work factor that must be evaluated, and the ability of the heart to carry this load should be determined as nearly as possible.

The woman heavy with child is prone to have some shortness of breath, palpitation, and even some edema from the purely mechanical effects of the gravid uterus in pressing upward the diaphragm, restricting respiratory movements, diminishing the vital capacity, and interfering with the venous return from the extremities. The increasing transverse position of the heart may cause slight shifts in the electrical axis. For these reasons it is often a difficult matter to determine, in the absence of the diagnostic murmurs, whether a woman has merely an exaggeration of effort symptoms or a neurosis or true heart disease.

Pregnancy increases the work of the heart considerably; the extra flow of blood required by a growing fetus in the enlarging uterus puts an indeterminable extra burden on even the normal heart and a strain of serious moment on every damaged heart. The increase in body weight, the reduced diaphragmatic movability, the displacement and rotation of the heart add to the embarrassment of the circulation. Consequently, it is not uncommon to have then the first evidence of cardiac trouble appearing during pregnancy. Under these conditions of strain any slight overtaxing of the heart may be an irreparable insult, precipitating a serious and often fatal congestive failure. The presence of any intercurrent infectious disease, even a mild sore throat or upper respiratory process, must be respected as serious and the patient put to bed to avoid further complications.

SOME GENERAL RULES CONCERNING GRAVIDOCARDIAC PATIENTS

It is hard to formulate any definite hard and fast rules concerning prognosis and measures to be undertaken in all cases. The great majority of patients with organic heart disease, especially those whose activities have not been restricted, can be subjected to a moderately hard labor or to a surgical operation with but slight if any increased risk. A fact not generally realized is that practically every patient who has been able to be up and about without respiratory embarrassment or substernal distress or congestion and edema will go through even a prolonged normal parturition or will tolerate almost any anesthetic regardless of the anatomic valvular lesion in the heart. That is, if the patient has been doing her daily routine without unusual symptoms, discomfort, dyspnea, puffiness, pitting edema or dropsy, she may be expected to do well under a considerable physical strain. Unfortunately, dependence must be placed almost entirely on the patient's story for the information as to the so-called cardiac reserve.

Innumerable tests of cardiac efficiency and exercise tolerance tests have been devised, but none have proved entirely satisfactory thus far. A discussion of these tests have been published elsewhere and is available.[16] The estimation of vital capacity and the cardiorespiratory test seem to be most promising. Pardee's [4] studies of dumb-bell exercise tolerance tests, standards and grouping for pregnant women are of the most importance and constitute a most practical contribution on this important subject. Pardee groups his gravidocardiac patients according to a functional classification based on the reaction to physical strain.

In this grouping class I embraces patients such as those described in the preceding paragraphs. Pregnant women in this class should swing, from between the legs to above the head, a 10 pound, or if the patient is poorly developed physically, a 5 pound dumb-bell from twenty to twenty-five times. This effort should call forth nothing more than a moderate amount of dyspnea and tachycardia, which subside in a minute or two.

Class II A patients show an excessive reaction to the dumb-bell test with marked dyspnea and tachycardia. This group embraces those who can perform the usual normal physical activities but who have discomfort in doing these. Such persons, however, have an increase in shortness of breath after climbing stairs, lifting heavy articles or walking up grades.

In Class II B there are the patients in whom the reaction to the dumb-bell exercise is so excessive that the exercise cannot be carried out on account of palpitation or dyspnea. Those patients who are unable to execute the more difficult features of ordinary physical activity, such as climbing two flights of stairs, or walking at an ordinary rate for a half mile, on account of fatigue, shortness of breath, or palpitation, are grouped under this class.

Class III includes those patients who cannot perform the simplest physical activity, as walking 200 or 300 feet or climbing one flight of stairs without resting or doing any housework without fatigue, shortness of breath or palpitation. A patient in class III cannot perform the dumb-bell exercise more than five or six times.

---

[16] Herrmann, George: Chronic Cardiac Valvular Disease, Oxford Medicine 2, pt. 2, chap. xiii, p. 492 (1) to 492 (70).

In a series of more than a hundred cases, deaths from heart failure during labor occurred only in patients of classes II B and III. Thus, gravid patients of classes I and II A were considered and actually proved to be able to withstand the strain of labor. The duration, character, severity and effects of the extra load placed on the heart in labor are unpredictable and infinitely greater than would ever be imposed by any ordinary surgical procedure under a reasonably smooth anesthetic of even two or three hours' duration. It is therefore certainly safe to regard the patients of classes I and II as good surgical risks, those of class II B as fair and those of class III as poor.

DEFINITE DANGER SIGNALS

It is only in the presence of such lesions as (*a*) bundle branch block or (*b*) incontrollable auricular fibrillation, especially with hyperthyroidism, (*c*) syphilitic aortitis without or with (*d*) anginal failure, and (*e*) high grade congestive heart failure that general anesthesia, especially ether, is contraindicated. Especially is this so when there is any edema of the lungs.

If a general anesthetic is found to be necessary, nitrous oxide or, better still, ethylene is to be preferred as far as the circulation is concerned. Spinal or local anesthesia, even for cesarean section, is by far the safest method to use in gravidocardiac patients.

It is most desirable to reestablish circulatory equilibrium by the use of digitalization, coronary vasodilation, and rest in bed will promptly get most patients into a desirable condition for operation.

In the case of surgical conditions in patients with disease, it is often a matter of choice, the question being as to whether the patient is going to gain more by taking the risk, or whether it might not be better not to take the risk. In the obstetric cases, however, there is no choice; something must be done. The patients that present themselves late in pregnancy with labor imminent or even under way, and in cardiac failure, bring out that point forcibly. In pregnancy with mitral stenosis and congestive heart failure, a truly critical emergency exists. These patients must immediately be given careful attention; they must be put to bed in a hospital under careful medical supervision and kept there until complete restoration of compensation is accomplished before labor is induced or operation is undertaken.

The pelvic measurements and size of the fetus, length and difficulty of previous labors, the degree of completeness of the reestablished circulatory function and the character of the cardiac damage determine the procedure to be pursued in any given case. It is desirable always to make as short and easy as possible the second stage if labor is instituted or allowed to proceed. This can be accomplished by the use of instrumental aids in delivery. The use of a tight abdominal binder immediately after delivery is a prophylactic measure against postpartum collapse or shock.

In all patients who have had serious congestive failure, the chances of survival of the child in an anoxemic uterus are poor, and delivery should be contemplated as soon as a viable child can be expected; that is, at the end of seven and a half months' gestation. By far the safest and simplest method of delivery is cesarean section under local anesthesia. Sterilization can be accomplished at the same time with little difficulty. Most gravidocardiac patients, even those with mitral stenosis and serious congestive failure, will respond to carefully supervised medical care and can be subjected to operation with assurance of satisfactory results if every detail of preparation and of after-care is conscientiously attended to. The medical management determines in a large measure the degree of success of the whole undertaking.

SUMMARY AND CONCLUSIONS

Twenty-four cases of heart disease in pregnant women are grouped in the order of seriousness and the various complications commented upon. Disturbances in the mechanism of the heart beat in pregnant women are especially stressed.

The importance of electrocardiographic studies, repeatedly done, in gravidocardiac patients is emphasized.

Bundle branch block, its serious significance and the hopeful possibility of the temporary transient nature of the condition are demonstrated.

Auriculoventricular block, fibrillation, and the less serious abnormalities and their effects in the cardiac function are commented on and illustrated. The state of the heart muscle is of the utmost significance.

The alleviation of congestive heart failure before permitting labor or surgical delivery to proceed is found to be paramount for success. Ether was found to predispose to fatal pulmonary edema in patients with the lung congestion of mitral stenosis. Of general anesthetics, ethylene is the choice as far as the cardiac condition is concerned, but local anesthesia is by far the safest to use.

Acute rheumatic endocarditis occurring during pregnancy responded to treatment and subsided about as it does in nonpregnant individuals.

Extensive and usually fatal pulmonary thrombosis is shown to occur relatively frequently in instances of serious idiopathic myocardial degenerative changes.

1551 Canal Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. REID AND DRS. HERRMANN AND KING

Dr. Harold E. B. Pardee, New York: I want to emphasize the point which Dr. Reid attempted to bring out: that by statistical studies it should be possible to determine the effect of pregnancy on the longevity of these patients. The idea that they are hard to deal with is well founded, for the reason that so many of them develop cardiac failure and come under observation in the large hospitals for the first time. By proper prepartum care it should be possible to prevent serious cardiac failure and this is the feature of pregnancy complicated by heart disease that I particularly want to emphasize. Two things should be determined in every patient. First, it must be determined whether or not she has heart disease. A patient with heart disease may still be a good candidate for pregnancy, but she must be watched during pregnancy, the degree of cardiac reserve determined, and precautions taken to make sure that failure is not setting in. During labor particular care must be taken to recognize the onset of failure. The best procedure is to count the pulse and respiration every half hour. The pulse should not go over 105 or 110; the respiration should not go over 28 or 30. If they reach those figures it is a sign that cardiac failure has set in, and labor must be ended promptly. If labor is not far enough advanced, the patient should be given a large dose of morphine and allowed to rest. A great deal of harm is done by operative procedures during severe cardiac failure, particularly intra-uterine procedures through the vagina. Cesarean section seems to be well borne, but even this should not be done if the patient shows marked cardiac failure, if it is possible to wait for the results of medical treatment. If a better state of cardiac function can be achieved, the mortality will be very low. Whether a woman can go through a pregnancy or not often depends on sociological rather than on pathologic factors. The same woman, if everything is done for her, might be able to go through without developing cardiac failure, whereas if she must take care of her children and her house she might not be able to do so. So sociology enters into the prognosis and also into the question of sterilization. The lesion should not be considered the sole determining factor. The cases of Drs. Herrmann and King show that serious cardiac failures may occur and yet even after this delivery may be successful.

Dr. Frederick H. Falls, Chicago: The main factor to know about in pregnancy complicated by cardiac disease is, What can the heart do? This should also serve as the criterion as to whether or not the patient should be allowed to become pregnant. If one finds the functional capacity of the heart good throughout pregnancy, even in the more serious types of cardiac diseases, pregnancy may continue to a satisfactory conclusion. I agree with practically everything presented in both papers in connection with the management of the cardiac case. Cardiac patients are apt to have premature labor and this may be relatively painless. Not infrequently, women with cardiac lesions, especially in the presence of decompensation, will have strong uterine contractions without knowing it or without letting the attendants know. Precipitate premature delivery may occur as a result. There is another point to be emphasized in connection with the handling of these cardiac patients: There may be a latent period after delivery or two or three days before a sudden collapse and death. I have seen this unfortunate experience two or three times. The patient seems to be entirely out of danger and suddenly there is a circulatory collapse and death. These patients should be observed and treated just as carefully post partum as ante partum. When acute dilatation of the heart occurs, I have used oxygen inhalation before and after the delivery with considerable beneficial effect. When cesarean section is indicated because of decompensated heart lesions, I do the classic operation with the patient in the modified Fowler's position. The operation is done under local anesthesia or a combination or local anesthesia with a little ethylene. I feel that this gas is safer than ether. Group 4 of Drs. Herrmann and King's cases, the toxic type of cardiac disease, I feel contains probably some cases that present a latent hyperthyroidism. I have seen patients with serious myocarditis secondary to hyperthyroidism. These patients improved markedly after pregnancy and labor were over. I feel that the cooperation of the internist should be sought before the follow-up period. When possible, the internist should be consulted early in pregnancy.

Dr. Hyman J. Epstein, New York: I am not sure that, whenever a cardiologist gives a bad prognosis in any case, the prognosis is bad. Often the cardiologist has advised against pregnancy and the young mother did not take the advice and delivered absolutely normally and without any complications. On the other hand, I have had cases that I thought were absolutely safe, and the electrocardiogram corroborated the observations of the cardiologist and yet such patients died, not during labor but immediately after labor. Of course, there is an explanation. Pregnancy is a pathologic process severely affecting previously damaged organs. And just as the kidney can become damaged when least expected, is it not reasonable to assume that a previously damaged myocardium may succumb to pregnancy? Usually young women can go through a pregnancy quite well. But an older one who has had several pregnancies is more apt to die. Not enough stress has been laid on the effect of pregnancy on a damaged myocardium. If the cardiologists would look on the heart just as much as on a damaged kidney, these patients could be advised before they become pregnant whether they should or should not take the risk. When they are pregnant, there is no better way than conservative expectant treatment, the cardiac condition being treated and the pregnancy being left to nature. Cesarean section is not more helpful than normal delivery. The fact of the matter is that it is not labor that kills them but the pregnancy. The term labor, in the sense of work, is a misnomer; especially when one sees how easily the cardiac patients go through the process of delivery.

Dr. W. D. Reid, Boston: What Dr. Epstein said about prognosis would be nice if we felt we could do it. I do not think it is possible for any man, whether he is a cardiologist or not, to determine prognosis so accurately. But a considerable estimate can be made. What I wanted to stress is that there is some evidence that 5 or 10 per cent of women with definite heart disease die during pregnancy. Those are average figures. I would like to see a bit more optimism and say that in from 90 to 95 per cent of these proved cases the woman survives. It is because I was trained to believe so differently that I have had to delete some of my own pessimism. The problem can be very obscure. It seems to me that much of it is not so obscure but is simpler and clearer; but, of course, when the percentage of nonrheumatic hearts is smaller, it requires more and more knowledge of internal medicine and cardiology to pick them out. It seems, though, that the physician in charge of the pregnant cardiac patient, be he general physician or obstetrician, must know a good deal about internal medicine and heart disease, and when possible he should avail himself of one who knows those fields better; otherwise he has to do it alone. The best way, as in many other things, is probably through cooperation.

Dr. G. R. Herrmann, New Orleans: I have little more to add. The points commented on by Dr. Pardee and Dr. Falls were well taken. I would be willing to agree with them in toto, and even with some of Dr. Epstein's radical comments. Our errors are many from the point of view of exactness in internal medicine, but we do have criteria to follow that are fairly reliable in I might say 75 per cent of the cases. That is about as high an average as can be expected. The ordinary criterion that can be followed with considerable safety is that if the woman is up and about in her pregnancy and able to carry along her ordinary activities of life without much increase in dyspnea other than that from the mechanical factors of pregnancy, she will be able to go through her labor without much difficulty. In other words, if she has a pretty good cardiac reserve she is a good risk regardless of her valvular defects. This can be further estimated by the simple dumb-bell test that Dr. Pardee has brought forth and confirm one's opinion as to her myocardial efficiency. Prognosis is merely a guess, in most cases especially, in the prospective bride or primiparous patient, and here again the sociological point which Dr. Pardee brought out is of much importance. If the woman is going to be in such an economic state that she can have help throughout her life and all the cares of the children will not be on her shoulders, she may expect to live out the ordinary span, as Dr. Reid said, without much added distress. If, however, she is of the great middle class and has a mitral stenosis with already some symptoms of failure, her prospects are mighty poor for a long and full married life without distress, cardiac invalidism and early death.

When Parents Are Related.—When parents are closely related, the gene defects of the two are likely to lie in the same pairs. For they have gotten part of their genes from the same ancestors, and some of these common genes are likely to have been defective. In unrelated parents, on the other hand, the gene defects have arisen independently, in different ancestors, and are therefore not likely to lie in the same pairs. This is the reason why unrelated parents, and particularly those belonging to different racial groups, or coming from different parts of the country, frequently give superior offspring. All this has its obverse side. By the production of new combinations in which the genes of the parents supplement each other, superior individuals are produced. By the taking apart of these combinations and the making of new ones in which the genes are not supplementary, inferior individuals are produced. The method of recombinations may work to produce defectives as well as normals, fools or knaves as well as geniuses. . . . When there is mating between two normal individuals each of whom have certain defective genes in the same pairs, to some of their offspring each will contribute a defective gene of the same pair. The result is the production of defective individuals.—Jennings, H. S.: The Biological Basis of Human Nature.

TREATMENT OF NONTUBERCULOUS SUPPURATIVE PNEUMONITIS, ABSCESS AND BRONCHIECTASIS [*]

JOHN ALEXANDER, M.D.
ANN ARBOR, MICH.
AND
WILLIAM W. BUCKINGHAM, M.D.
KANSAS CITY, MO.

There exist such widespread pessimism and confusion with regard to the treatment of bronchiectasis, abscess and allied nontuberculous suppurative conditions of the lung that we believe it should be of value to present what we consider the most useful therapeutic procedure in view of our own clinical experience and the opinions of others.

The term "suppurative pneumonitis" has been widely adopted to include the various nontuberculous cavernous and noncavernous pulmonary lesions and their combinations in the same patient. While the term is accurate and in the interest of simplicity, it gives no satisfactory conception of the many different forms in which this disease presents itself, each of which demands highly individualized consideration and flexibility with respect to treatment.

Until relatively recently, accurate diagnosis of the exact character of the lesions of suppurative pneumonitis and the factors that determine their onset and progression or regression have been little understood, and effective treatment has therefore often been a matter of chance. Indicative physical signs are often surprisingly fewer than the extent of the lesions would seem to promise, and they are not rarely misleading, as may be roentgenograms of perfect quality. Iodized oil[1] pneumograms (fig. 1) and bronchoscopy, together with a better appreciation of the etiologic factors and of the tremendous value of the patient's medical history, are largely responsible for increasing accuracy of diagnosis and for the development of therapeutic measures and their increasing effectiveness.

We feel strongly that treatment of the early or noncavernous stage of pulmonary suppuration is a problem that is chiefly concerned with local rest and the patient's general resistance and is, therefore, almost always the concern of the internist. Appropriate nonsurgical treatment in this phase of the disease frequently will result in cure. If it does not, and the patient enters into the next phase of the disease when extension of the pneumonitis has ceased and when cavitation is well established and natural bronchial drainage may be inadequate, the problem often centers on mechanical factors and demands some type of surgery for its successful solution. At this time surgery is conservative, not radical, therapy in that it tends to prevent further destruction of pulmonary tissue with the associated dangers of hemorrhage, extension of the suppurative pneumonitic involvement, cerebral abscess and the permanent damage to kidneys, heart and vessels that sometimes complicates prolonged suppuration. We believe that persistence in nonsurgical measures beyond the optimal time for surgical intervention not rarely is chiefly, although indirectly, responsible for the fatal outcome that may follow a too late operation that is performed out of pity in the hope that a single chance of recovery is better than none at all. Internists often mistakenly tend to attribute these bad results to surgery rather than to their own delay in recommending surgery during the period when its opportunity to cure was at its best.

Briefly, there is an early stage of suppurative pneumonitis when medical treatment is best and often cures. If it fails to produce more than slight improvement, the patient enters a stage of the disease when surgery may offer incomparably the best chance of cure. This period is succeeded by a terminal stage in which the chance of cure by any means has been practically lost and in which operation may be performed only with the understanding that the risk is great and the chance of cure slight.

EARLY STAGE OF SUPPURATIVE PNEUMONITIS

The lesions of the earliest stage of suppurative pneumonitis are usually a purulent infiltration of the alveoli and interstitial tissue of the lung with an associated infection of the bronchioles and smaller bronchi. As these lesions age, a varying amount of new connective tissue may form and contribute an element of fibroid pneumonitis. The causes of the lesions are many and have an obvious bearing on prophylaxis and treatment. Chief among the causes are the following: 1. Aspiration of infected material, with the consequent inflammatory reaction, may more or less completely occlude the bronchi and cause stasis-infection of the lung distal to the occlusion if the obstruction is not soon overcome by action of the cilia, coughing, deep breathing or bronchoscopic aspiration. The most commonly aspirated material comes from infected mouths or sinuses. Such aspiration may occur during sleep but most frequently during operations on the nose, tonsils, mouth and upper part of the abdomen or during general narcosis for operation on any part of the body. Pus may reach and infect the lung through a bronchopleural fistula or from an empyema or subphrenic abscess, or food may spill into the tracheobronchial tree because of pharyngo-esophageal diverticulum or esophageal obstruction by cancer or benign stricture or because of an esophageobronchial fistula. 2. Aspiration of any type of foreign body may infect the lung. 3. Prolonged bronchial obstruction by intrabronchial or extrabronchial neoplasms, aneurysms, strictures, foreign bodies and mucous plugs such as are believed to be responsible for postoperative atelectasis may cause suppurative pneumonitis through stasis of trapped secretions. 4. Incomplete resolution of pneumonia may be the cause. 5. Bacteremia may be responsible for emboli that establish infected pulmonary infarcts, or sterile infarcts may become infected by organisms normally resident in the lung. 6. Pulmonary infection occasionally occurs from extension of infection through the lymphatics from neighboring foci. 7. Wounds of the lung, especially when a foreign body remains, may cause a suppurative pneumonitis.

Indications for treatment are clearly implied by some of the etiologic factors just mentioned, as bronchoscopic or surgical removal of foreign bodies, drainage of an empyema, treatment of sinus disease, infected gums and alveoli.

Removal of secretions that lie within the bronchi and, through stasis, tend to maintain and increase infection within the lung, is of great importance. Coughing that raises these secretions is of the utmost value; only such coughing as is "dry" or excessive should be checked by opiates. In the very early stages of bronchial occlusion by secretions, deep breathing that is voluntary or, better, stimulated by a few minutes' inhalation through an anesthetic mask of 5 per cent carbon dioxide in 95 per cent oxygen every fifteen or thirty minutes or every one, two or four hours (according to the need for and effectiveness of this treatment) and followed by voluntary coughing usually will succeed in evacuating the secretions. Postural drainage by placing the patient on one side or the other, or with the upper part of the body more dependent than the lower, will frequently cause evacuation of secretions when other methods have failed. The most effective method of postural drainage for most patients who are not too ill and whose secretions lie in the lower half of the lung is placing the patient across the bed with his head and shoulders close to the floor (fig. 2). When these measures fail, one or more bronchoscopic aspirations may be rewarded by an excellent result.

[1] Various methods of introducing the oil are discussed by Pritchard, Stuart; Whyte, Bruce; and Gordon, J. K. M.: Radiology 8: 104 (Feb.) 1927.

Patients in the early stages of suppurative pneumonitis, including those who may be afebrile, should be required to remain at absolute rest in bed until several weeks after all sputum and other important symptoms of the disease have disappeared and until the physical signs and roentgen evidence of the pulmonary infiltration have largely disappeared. This has been emphasized by Stuart Pritchard.[2] Insistence on this is probably vital in combating recrudescences of the disease and development of the grave conditions of abscess or bronchiectasis.

Further measures of value in the management of these patients by the so-called sanatorium regimen are the stimulation of fresh air, a high caloric diet of not distasteful bulk, great fluid intake and, when necessary, transfusions of blood. The general plan of treatment just described, with suitable variations, should be followed in all stages of suppurative pneumonitis, including abscess and bronchiectasis. When spirochetes are present in the sputum in the acute and subacute stages of cavernous or noncavernous suppurative pneumonitis, several intravenous courses of neoarsphenamine may prove of great value. In the chronic stage the lesser chance of a favorable result should be weighed against the greater chance of damage to kidneys and liver.

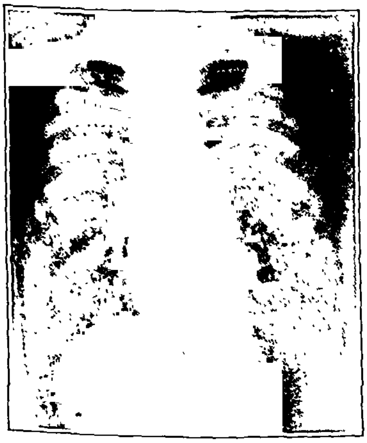

Fig. 3.—Arrows indicate area of chronic suppurative pneumonitis into which iodized oil has not penetrated. Sputum, 75 cc.; temperature, 101 F.; no foreign body by bronchoscopy. Temporary interruption of phrenic nerve was followed by gradual disappearance of lesion and symptoms.

If these various measures fail to cause a sufficiently rapid improvement in the condition, we believe that a temporary interruption of the phrenic nerve on the diseased side is definitely indicated (fig. 3). The resulting paralysis and rise of the hemidiaphragm relax and rest the inflamed lung and are important factors contributing toward cure. From four to six months later the diaphragm will begin to function again.

ABSCESS[3]

In spite of faithful treatment, an area of suppurative infiltration may rapidly or slowly be excavated by necrosis to become an abscess or multiple abscesses, or by the action of putrefactive organisms to become gangrenous. Even now, if less than from six to ten weeks has elapsed since the onset of the disease, continuation of the same treatment will bring about a cure in perhaps 30 per cent of cases of abscess. Drainage of an abscess cavity at this early stage is dangerous because, through direct trauma to the inflamed lung combined with the disturbance in the function of coughing and expectorating that follows wide opening of the abscess and of the peripheral bronchi to atmospheric pressure, the suppurative pneumonitis may be caused to spread. In those patients in whom emptying of the abscess through the bronchi is unsatisfactory in spite of postural drainage, bronchoscopic aspirations should be given a fair but not too prolonged a trial. Although the bronchoscopist rarely is able to enter the abscess cavity with the aspirator, he does aspirate the secretions from the draining bronchi; this manipulation is followed by much coughing, which probably tends to empty the abscess itself and, at any rate, often seems responsible for cure. We feel that therapeutic intrabronchial instillations of iodized oil have not sufficiently proved their value in either abscess or bronchiectasis. We have had no experience with Castex, Heidenreich and Repetto's[4] intrabronchial neoarsphenamine.

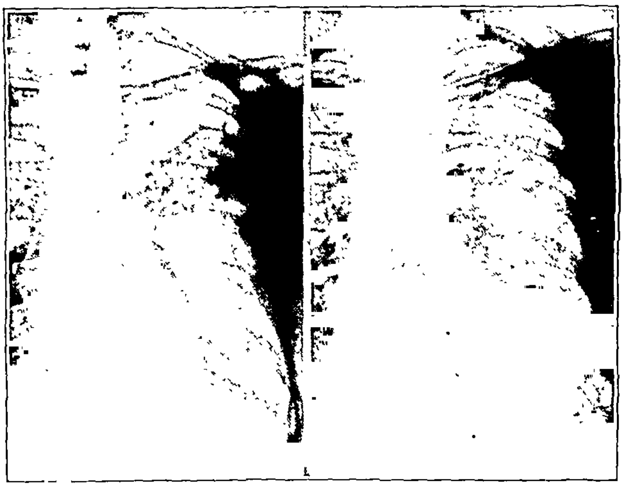

Fig. 4.—Left, suppurative pneumonitis with large irregular abscess eleven weeks after extraction of abscessed teeth; 75 cc. of foul sputum; loss of 25 pounds (11.3 Kg.). Right, disappearance of lesions and symptoms five months after temporary interruption of phrenic nerve; six weeks after operation lesions and symptoms were greatly improved.

If the abscess still persists, a temporary phrenic nerve interruption should be performed. We have seen most satisfying results to follow it in the prechronic stages (fig. 4), as well as only temporary improvement or, occasionally, no improvement at all; but we have never seen harm from it. This operation has served us better than any other measure in the control of all degrees of hemoptysis in abscess, as well as in bronchiectasis.

[4] Castex, M. R.; Heidenreich, A., and Repetto, R. L.: Bull Acad. de med. **95**: 131 (Jan. 5) 1926.

A few cases of abscess, perhaps complicated by dangerous hemoptysis, that persist may be treated by artificial pneumothorax and the results are occasionally astonishingly good. We agree with Landau and Held[5] that pneumothorax, if used at all, should be limited to the early stages of abscesses and preferably those in the upper part of the lung where adhesions seem to form later than over abscesses in the lower lung. We further believe that pneumothorax should not be used for those abscesses that dwell in the peripheral portion of the lung, because here adhesions usually form very early and either prevent an adequate collapse of the involved portion of the lung by the pneumothorax or in being stretched may tear the infected lung and be responsible for a highly dangerous form of empyema. For this reason every pneumothorax should be induced with great caution, not more than 300 cc. of air being used for each filling until the fluoroscope and roentgenograms show that no adhesions exist in the neighborhood of the infected portion of the lung. Also, the peripheral type of abscess does less well with pneumothorax than does the hilar type because the necessary bronchial drainage is usually less free.

It should be recognized that any extensive pneumothorax that is unsuccessful may create a condition of great danger that the surgeon must face if drainage of the abscess should later prove necessary. The reason is that expansion of that part of the lung which is to be entered for drainage, and its firm adhesion to the thoracic wall, must be obtained before drainage is undertaken in order to prevent spilling of the pus from the abscess into the pneumothorax, which would cause a highly dangerous empyema. We advise against the use of artificial pneumothorax in abscess except under unusual circumstances.

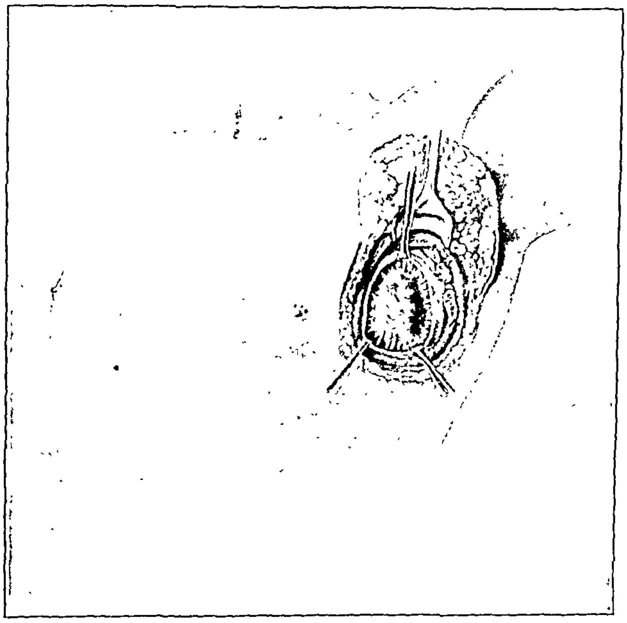

Fig. 5.—Axillary approach for drainage of upper lobe abscess: After a disk of parietal pleura was removed, the lung was found apparently adherent to the parietal pleura, but when the edges of the pleura were lifted several nonadherent places were discovered inferiorly that required packing for several days before the abscess could be safely opened without causing an empyema.

The lung and its contained abscess cavity may be relaxed or compressed locally by the operation of extrapleural pneumolysis. Sauerbruch[6] and Mittledorpf[7] are enthusiastic about this operation and use paraffin to fill the space created between the parietal pleura and ribs. F. P. Miller[8] has devised a useful pneumatic bag as a filling. Roux-Berger[9] reported three successes and two failures after extrapleural pneumolysis and considers the operation best for multiple abscesses. We have employed it only once in nontuberculous cavitation, using the pectoral muscles as a filling, with complete success in a chronic upper lobe abscess with excellent bronchial drainage. Sauerbruch states that if the operation does not close a cavity it will cause the formation of pleural adhesions and make future surgical drainage safer. Pneumolysis may prove valuable in severe hemoptysis.

A considerable number of abscesses will remain open and more or less poorly drained by the bronchi in spite of the best of medical treatment combined with bronchoscopic aspirations and interruption of the phrenic nerve and perhaps also with pneumothorax or pneumolysis. In general, if this is so six, eight or ten weeks (according to the circumstances) after the onset of the disease, and if the patient is not clearly showing signs of genuine improvement, surgical drainage of the abscess must not be delayed, because surgery offers little hope in the later stages of the disease. Sauerbruch[6] is of the opinion that drainage should not be postponed more than eight weeks after the onset of a metapneumonic abscess and that it should be used earlier for putrefactive suppuration or gangrene.

The technic of the operation will not be described here, but we will mention several aspects of the subject that we consider important:

1. Local anesthesia, or *no anesthesia* at all during cauterization of the insensitive lung, is superior to inhalation narcosis, which we believe increases the risk of causing extension of the pneumonitis.
2. The axillary is preferable to the anterior approach in most abscesses of the upper lobe; the posterior or posterolateral is the obvious approach to the lower lobe.
3. Removal of ribs wide of the limits of the abscess is preferable to restricted resections in that it affords a safe field of exposure for the operation and later aids in closure of the abscess and operative defect by permitting sinking in of the decostalized thoracic wall.
4. One of the greatest technical dangers of the operation, and one that must be avoided, is infection of the pleurae when the visceral and parietal pleurae are not completely and firmly adherent in the field of operation. Even if exposure of the external surface of the parietal pleura reveals it as opaque and even if the lung cannot be seen moving with respiration beneath it, we excise a disk of parietal pleura five or more centimeters in diameter before entering the lung with either a needle or a cautery. Further, before opening the lung, we lift the entire remaining cut edge of parietal pleura in order to see whether or not it and the visceral pleura are solidly adherent and serving as a complete barrier between (*a*) the pus that will flow against it after opening of the abscess and (*b*) the pleural cavity that may

[9] Roux-Berger, J.-L.: Bull. et mém. Soc. de chir. de Paris **47:** 268, 1921.

be unobliterated by adhesions beyond that barrier. Frequently we have seen only one or two tiny defects in this barrier of pleural adhesions that warned against opening the abscess until gauze packing for several days had caused new adhesions to close these openings (fig. 5). If exposure of the parietal pleura should reveal it as thin and not adherent to the lung it must, of course, not be opened at all until several days of gauze packing against it have caused firm adhesions through which the abscess may be safely drained at a second stage of the operation. Sewing the lung to the parietal pleura is dangerous because organisms may pass through the needle tracks from the lung into the pleural cavity.

5. We are opposed to the use of a rubber tube to drain an abscess. Even though soft, it may, by pressure necrosis, erode the already ulcerated wall of a blood vessel and cause a dangerous hemorrhage. We prefer to cauterize a wide opening to the abscess—wider than the abscess itself, unless it be a huge one—so that the abscess may be packed with medicated gauze that is moist or treated with petrolatum every one or two days until the cavity has filled in from its very bottom.

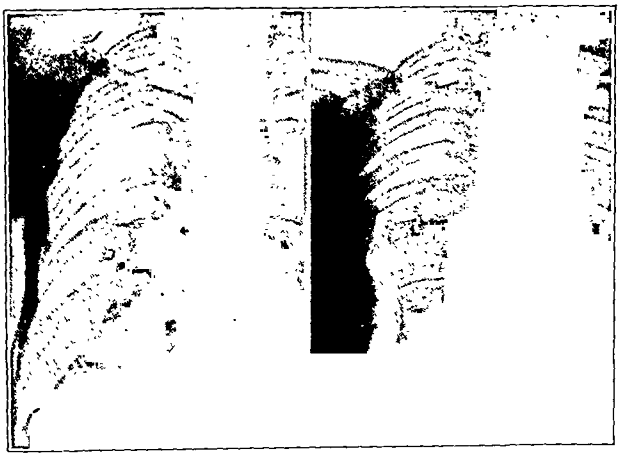

Fig. 6.—Left, abscess filled with air and pus seven weeks after partial gastrectomy; arrows indicate limits of abscess as determined the next day at open operation. Right, clear area lateral to costal stumps due to operative defect; arrow indicates position of a separate abscess, 9 by 4 cm., containing pus but no air, suspected when sputum did not disappear after drainage of other abscess and drained nine days after first operation.

6. The abscess should be kept packed snugly with moist medicated gauze or gauze on which petrolatum has been spread, so as to occlude the open bronchi. If this is not done, or when a tube is used for drainage, coughing tends to be ineffective in raising secretions from the lung, because a part of the force of the cough is dissipated through the open bronchi.[10] No attempt should be made to close a residual bronchocutaneous fistula until all sputum and all purulent discharge from the wound have ceased; this cannot be expected if a second inadequately drained abscess or a bronchiectasis is associated with the originally drained abscess. Otherwise most small fistulas will close spontaneously or may be aided by occasional cauterization of the mouth of the fistula with a stick of silver nitrate. If a patient with a large fistula wishes to avoid such inconveniences as never taking a tub bath and always wearing a small dressing, the bronchial fistula may be closed by mobilizing its end for about 1 cm., excising the scar at its mouth, closing the open bronchus by suture, and covering it with a flap of neighboring extracostal muscle, pedicled at the edge of the defect in the lung and thoracic wall, and finally mobilizing and closing the skin. Properly performed, this operation results in a large proportion of primary closures. Lebsche[11] has described an operative method of closing multiple bronchial fistulas.

Extrapleural paravertebral thoracoplasty is not indicated in any but the chronic stage of abscess; here its best results are obtained in abscesses with thin compressible walls or in small single or multiple abscesses, preferably those with which there is much intrapulmonary fibrosis. Persistence of sputum or an undue amount of discharge from the wound several weeks after drainage of an abscess probably indicates that there is a second abscess (or possibly an associated bronchiectasis) that requires drainage, even though it is not evident roentgenologically as a cavity with a fluid level (fig. 6).

Many cases of abscess that have not been drained at the proper time, and some cases that have been so drained, proceed slowly or rapidly to extension of the suppurative infiltration within the originally involved lobe and to other lobes. Cavitation is likely to follow and as a result there are a number of cavities of various sizes that either intercommunicate or are isolated from one another. Patients with such abscesses are usually in poor general condition and are not good operative risks.

Certain very extensive multiple abscesses cannot be well drained in the ordinary sense. For them, provided they are confined to one lobe, some type of lobectomy should be considered, because only complete eradication of the diseased tissue can cure them.

BRONCHIECTASIS[12]

It is not clearly understood why some cases of noncavernous suppurative pneumonitis that do not heal progress to abscess formation and why others progress to bronchiectasis. One obvious factor is that location of the principal lesions in the parenchyma determines abscess formation and in the bronchial walls bronchiectasis. David Smith[13] believes that the degenerating action of Vincent's spirochetes on the bronchial walls is responsible for their dilatation in much the same way that the spirochetes of syphilis are responsible for aneurysm of the aorta. It seems likely that, when fibroid pneumonitis is associated with degeneration of the bronchial walls, contraction of the fibrous tissue within the lung tends to dilate the bronchi by traction on their walls. This most frequently occurs after incomplete resolution of a pneumonia and in chronic empyema. Sauerbruch[6] is of the opinion that many cases of bronchiectasis are of congenital origin.

If, as we believe, a large proportion of cases of bronchiectasis develop more or less slowly from the initial lesions of simple suppurative pneumonitis, it is of great importance that every effort be made to cure these initial lesions before they become transformed into bronchiectases. We have discussed under "Early Stage of Suppurative Pneumonitis" the prophylactic and therapeutic measures that we consider best.

[13] Smith, David: Relation of Vincent's Angina to Fusospirochetal Disease of the Lungs, J. A. M. A. 94:23 (Jan. 4) 1930.

Therapeutic procedure for an established bronchiectasis varies greatly according to the following conditions: 1. Whether the lesions are limited to one or more lobes, as determined by staged iodized oil bronchography of all lobes of both lungs. 2. The amount and foulness of the sputum and whether or not there are hemoptyses. 3. The general condition and age of the patient, his capacity for work and his mental attitude toward his disease. 4. The frequency of fresh attacks of bronchopneumonia and whether the disease has a tendency to be progressive or remain quiescent.

Bronchography occasionally reveals an extensive bronchiectasis in a patient who has no sputum—the bronchiectasis sicca of Bezançon. This condition, which implies little or no infection in the bronchial walls, is in our experience usually encountered in an upper lobe in which drainage is downward toward the hilus, although we have also seen it in the lower lobe. It is commonly associated with a fibroid lung and traction displacement of the mediastinal organs. In these cases the patients should be especially careful to avoid "catching cold" that might permanently establish infection in the bronchi. We believe that permanent interruption of the phrenic nerve, phrenicectomy, is indicated to help to satisfy the contraction of the fibrous tissue within the lung, which it does through the resulting rise of the paralyzed hemidiaphragm.

In all cases of bronchiectasis there is a special indication to treat an infected mouth and sinuses and to search with the bronchoscope for an intrabronchial foreign body that may not be visible, roentgenologically. Chevalier Jackson[14] states that 98 per cent of his cases of suppurative pneumonitis caused by a metallic foreign body cleared up completely after removal of the foreign body even when the symptoms had existed for years, but that a lesser percentage became cured when the foreign body was vegetal. In our experience, disappearance of sputum in the chronic cases has occurred much less often than it did in Jackson's experience. Obstruction of the bronchus by cancer or by benign tumor should be ruled out, as should an empyema with bronchopleural fistula.

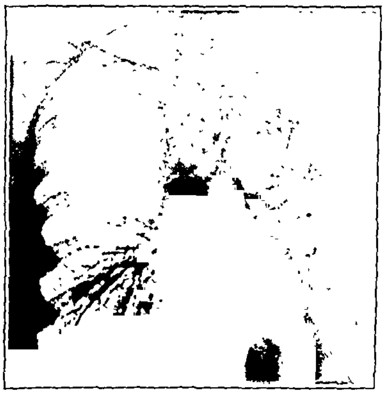

Fig. 7.—Saccular bronchiectases from apex to base of left lower lobe after sixteen years of profuse, foul and occasionally bloody expectoration. Two months before treatment the patient had a 500 cc. hemoptysis. Phrenicectomy and faithful postural drainage reduced 250 cc. of foul sputum to 20 cc. of odorless, bloodless sputum in seven months. The patient gained 12 pounds (5.4 Kg.).

We have had no experience with vaccines. Sergent[15] writes that he has seen no good from their use. With a picture of the pathologic anatomy of the lesions of bronchiectasis in mind it becomes apparent that cough mixtures can be of no real value, with the possible exception that such drugs as creosote may decrease the odor of the sputum. Blood transfusions should be used if the patient is very anemic and particularly as preparation for a major operation.

Occasionally bronchiectasis is associated with a large pulmonary abscess, a "bronchiectatic abscess," that may demand drainage as any other abscess would. Such drainage is likely to be followed by a bronchocutaneous fistula that will not close because of persistence of infection behind it. The multiple small abscesses which are, in fact, the bronchiectases themselves should not be drained in the ordinary way because such drainage is ineffective. Extensive drainage by staged cautery lobectomy will be considered later.

Bilateral bronchiectasis, or that involving both the upper and the lower lobes on one side, or unilobar bronchiectasis in a patient in poor general condition should not be treated radically. The mild general measures previously described may prove useful, and residence in an equable dry climate may improve sinusitis and lessen the incidence of attacks of bronchitis and bronchopneumonia which tend to increase the bronchiectases; also the sputum may be reduced in amount. Most important of all in the palliative treatment is the persistent use of postural drainage every two, three or four hours (according to the rapidity of production of sputum) during the waking hours and, if indicated, one or more times during the sleeping hours. By keeping the dilated bronchi relatively free from their stagnant secretions, infection in their walls tends to subside, the amount of sputum to be reduced, the odor and hemoptyses to lessen, and the patient's weight and general condition to improve. If postural drainage is ineffective in draining the purulent collections, weekly, or oftener, bronchoscopic aspirations should be tried. They often greatly relieve the patient but can scarcely be expected to bring about a cure.

When the disease is confined to one lower lobe, as it often is, and when the patient is in good general condition, more active measures may be employed. We believe that phrenicectomy should be the first to be tried (fig. 7). It often reduces the quantity and odor of the sputum and otherwise improves the patient. Sometimes it has no effect and a few times we have seen an increase in sputum but without apparent harm. In occasional early cases it alone may cure.

Artificial pneumothorax may cure an early but rarely a late case. Considerable improvement is occasionally obtained during maintenance of the pneumothorax, but this improvement is often partly or completely lost when the pneumothorax is abandoned and the lung expands. Considerable improvement during maintenance of the pneumothorax may, however, serve as an indication for an extensive extrapleural thoracoplasty, in the expectation of making the improvement permanent. We are disinclined to use pneumothorax except, perhaps, after phrenicectomy in the early stage of bronchiectasis, as permanently satisfactory results are not frequent and there is some danger of a complicating empyema.

Extensive staged extrapleural thoracoplasty has its principal value in (1) the rather rare type of bronchiectasis that is limited to the smaller or peripheral bronchi that are compressible because of their incomplete cartilaginous framework and (2) bronchiectases that are accompanied by great traction-displacement of the mediastinal organs, a condition that occasionally occurs as a complication of chronic empyema.

In the usual central type of bronchiectasis, in which the lesions occupy the larger bronchi, our experience agrees with Denk's[16] and Sauerbruch's[6] that thoracoplasty is often insufficiently effective and that the operative risk from aspiration pneumonia and cardiocirculatory failure is much greater than in tuberculosis. Hedblom,[17] Harrington,[18] and J. E. H. Roberts,[19] have, however, reported good results from thoracoplasty.

[16] Denk, W.: Deutsche Ztschr. f. Chir. **221**: 186, 1929.

If, after all the measures we have been discussing and that may be proper for a given patient have been tried, the patient is in reasonably good general condition and if he continues to have abundant foul sputum, perhaps with hemoptyses, and to remain in a mildly toxic condition, a lobectomy must be considered because now nothing but actual removal of the purulent, abscess-laden tissue can be expected to rid him of his obnoxious, dangerous disease. The miserable invalidism and usually eventual fatal outcome in advanced bronchiectasis are obvious reasons favoring a lobectomy. David Stewart[20] found that 60 of his patients had had 240 complications among them.

We are convinced that two-staged lobectomy is now firmly established as an operation of tremendous value for such patients as are discussed in the preceding paragraph. The operative mortality ranges between 20 and 30 per cent in the most experienced hands, which is a 50 per cent improvement within a period of the past three or four years. Krampf,[21] however, reports for Sauerbruch only a 10.7 per cent mortality in twenty-eight cases. Thoracic surgeons have profited much from their earlier mistakes and it seems quite likely that their more recent series of cases will show still lower operative mortality figures. The improvement that follows total removal of the only diseased lobe is truly remarkable and is in striking contrast to the pitiable condition of the patients before operation. Sputum usually disappears completely and, in our experience, which has been chiefly with the exteriorization method of lobectomy, most of our patients who have not been operated on too recently have had their residual bronchial fistulas completely closed by a plasty of pedicled muscle and two have closed spontaneously. Such patients may be classified as completely cured. Two of our ten patients were 5 years old at the time of operation, four others were less than 20, and all were less than 36. Cure at such age implies a great many years of normal life, whereas the outlook of the same patients without operation would have been wretched and almost hopeless.

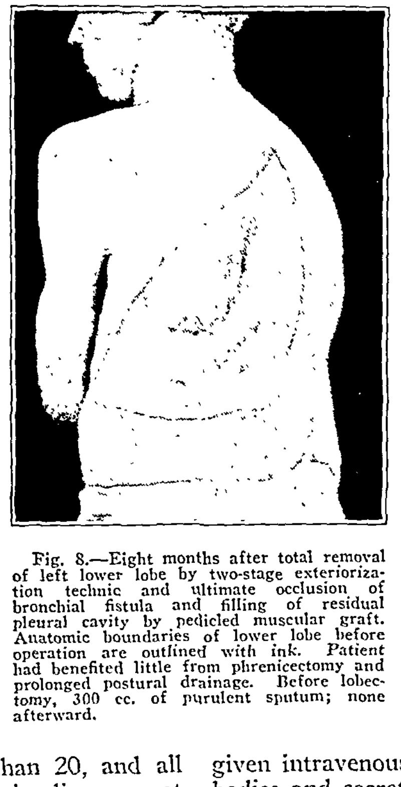

Fig. 8.—Eight months after total removal of left lower lobe by two-stage exteriorization technic and ultimate occlusion of bronchial fistula and filling of residual pleural cavity by pedicled muscular graft. Anatomic boundaries of lower lobe before operation are outlined with ink. Patient had benefited little from phrenicectomy and prolonged postural drainage. Before lobectomy, 300 cc. of purulent sputum; none afterward.

When in a given case we believe that the indications for lobectomy are clear, we place the facts with respect to risk and improvement squarely before the patient or his relatives. Almost all choose the operation if for no other reason than that the frequent coughing and abundant foul sputum during months or years have made life a burden. Failure of the various therapeutic measures that have been systematically tried before lobectomy is recommended tends strongly to influence the patients to accept lobectomy.

For cases in which the pleurae over the diseased lobe are extensively adherent, we recommend the staged cautery lobectomy that Evarts Graham[22] has so ably developed. Performed as Graham directs, the operation is an excellent one.

For cases in which the pleurae of the diseased lobe are not extensively adherent, and most are not, we believe that the exteriorization lobectomy described by Whittemore[23] is the operation of choice. Alexander will soon publish a description of certain modifications in the technic that seem to have proved of great value. Sauerbruch[6] favors extrapleural pneumolysis and Zaaijer and Suermondt[24] favor intrapleural pneumolysis and gauze packing as a preliminary to lobectomy. Although we have not used this, we at present prefer, on theoretical grounds, the exteriorization technic we use. Some surgeons advise extensive paravertebral thoracoplasty preliminary to lobectomy. We doubt whether this is important in bettering the operative conditions for lobectomy and we believe that it should not be used chiefly for this purpose because (1) it has a considerable operative mortality of its own and (2) it practically excludes from respiratory function the remaining lobe on the operated side, whereas this lobe continues to function after lobectomy by the exteriorization or cautery technic.

SUMMARY

1. Suppurative pneumonitis not rarely complicates operations, pneumonia and infections of the mouth and sinuses.

2. In the early stages of the disease, medical treatment is best and often cures. If it fails after a reasonable trial, surgery frequently offers an excellent chance for cure, provided operation is not unduly delayed.

3. The most useful medical and surgical methods of treatment are: sanatorium regimen; frequent postural drainage; elimination of mouth and sinus infection; neoarsphenamine given intravenously; bronchoscopic removal of foreign bodies and secretions; artificial pneumothorax; temporary or permanent interruption of one phrenic nerve; extrapleural pneumolysis; extrapleural thoracoplasty; drainage of an abscess; lobectomy.

4. Selection of the best therapeutic procedure for each of the types of suppurative pneumonitis must be highly individualized. The simplest appropriate measure should be chosen first, and as soon as it is seen to be inadequate the next more radical one used.

5. This article undertakes to describe what we believe to be a logical succession of the nonsurgical and surgical measures that we have found of value for various types of suppurative pneumonitis.

POSTOPERATIVE PULMONARY HYPOVENTILATION *

RICHARD H. OVERHOLT, M.D.
PHILADELPHIA

During the past decade, discussions of postoperative pulmonary complications have concerned themselves for the most part with pathologic processes within the lung itself. As a result of this, surgeons have been confronted with a rapidly changing nomenclature in relation to the pulmonary condition which so frequently follows abdominal operations and which later either disappears or progresses into a classic postoperative pneumonia. Hypostatic congestion, multiple embolic phenomena and pneumonitis are familiar conditions. More recently attention has been focused on the thick, viscid mucus, the bronchial tree, and atelectasis. After it was established that occlusion of a main bronchus caused massive or lobar collapse, the papers of Elwyn,[1] Mastics, Spittler and McNamee,[2] Lee and Tucker [3] and others began to appear in which were described a more diffuse process, a lobular atelectasis, presumably caused by mucous occlusion of smaller bronchi. Practically every writer on this subject has emphasized the sequence of events as follows: excessive and thickened bronchial secretion, inadequate bronchial drainage, the inhibition of the cough reflex, air absorption, and apneumatosis. To complete this conception, a nonfunctioning pulmonary tissue was finally provided which could progress into pneumonia if infection should be present.[4]

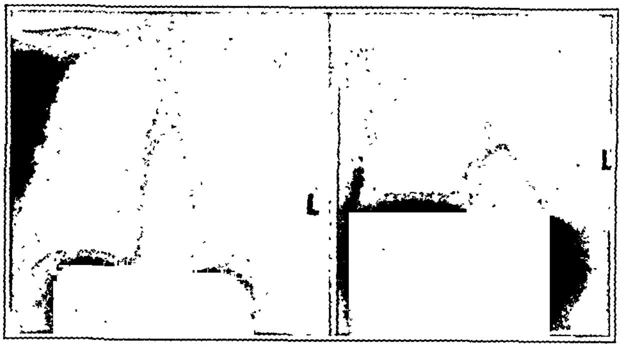

Fig. 1 (Mrs. E. S.).—Bedside roentgenograms made before and twenty-four hours after cholecystectomy. Uniform distance, bed position and exposure. Examination made at full inspiration. Elevated position of diaphragm and diminished thoracic volume are evident. Note increased density of hilus shadows and intensification of lung markings which make interpretation of postoperative roentgenograms difficult. Value of preoperative examination for comparison is demonstrated.

Recently, however, Van Allen [5] has shown that occlusion of anything less than a lobe bronchus does not result in atelectasis of that portion of the pulmonary tissue. In other words, lobular atelectasis cannot be caused by bronchial occlusion alone. This work suggests that one look outside of the bronchial tree and, perhaps, outside the thorax itself for the primary changes which deliver the postoperative abdominal case into a group in which the potentialities of pneumonia are great.

I propose in this paper to discuss variations from the normal anatomic and physiologic conditions below the diaphragm which occur after laparotomy and their effect on the position and activity of the diaphragm. I will present evidence which, I believe, indicates that pulmonary hypoventilation exists for a variable period of time after operation. The causative factors for hypoventilation and the extent to which it exists after operation have not been given the attention they merit because the clinician has focused his attention on the lesion above the diaphragm and has neglected the relationship of cause and effect.

Following abdominal operations, many patients complain of a "heavy feeling" or sense of oppression about the lower part of the thorax, often of dyspnea, or of an inability to "take a comfortable breath." Frequently breathing becomes predominantly upper thoracic in type. The exact length of time over which these complaints are made varies. The extent of the respiratory excursions during forced breathing is little more than that required for quiet breathing. Last year, in a routine study of the chests of patients before and after upper abdominal operations, Muller, Pendergrass and I [6] found a 75 per cent diminution of chest expansion after operation. The thoracic circumference became greater after operation. The measurements of the thoracic circumference during both phases of respiration after operation corresponded closely to those at fullest inspiration before operation. On auscultation diminished breath sounds, often râles, and, occasionally, tubular breathing were heard posteriorly over the bases. In some patients, varying degrees of cyanosis were present. These observations indicate that free, normal respiratory activity is interfered with after the abdomen has been opened.

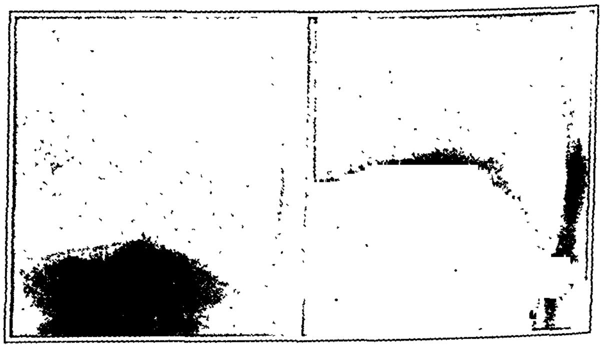

Fig. 2 (Mrs. E. S [illegible] made before and twenty-four hours [illegible] elevation of diaphragm. The [illegible] patient was uneventful.

A surprising difference was noted in roentgenograms taken in the same position, in the same phase of respiration, and with the same exposure, before and after abdominal operations. The superior-inferior diameter of the thorax was greatly diminished in the postoperative films because of a marked elevation of the diaphragm. Diaphragmatic excursions, as observed under the fluoroscope, were found to be reduced from 33 to 50 per cent after operation. In the postoperative roent-

genograms of 75 per cent of the patients who showed no clinical evidence of a pulmonary complication, there was present an increased density of the trunk shadows which produced a triangular area of density in the lower lobes (figs. 1, 2 and 3). Examination of the routine postoperative roentgenogram disclosed a condition similar to that previously called by our roentgenologists areas of pneumonitis, bronchopneumonia or lobular atelectasis. Recently, Patey[7] and Brunn[8] have confirmed our observations in the postoperative patient.

The study was extended to include patients before and after lower abdominal operations. In each instance, regardless of the type of anesthetic used, an elevation of the diaphragm is found (fig. 4). There is a retraction of the lower lobe of the lung and a shift in the position of the lower bronchi. The heart is lifted, its horizontal diameter is increased, and it assumes a bulging, squat position. Lateral roentgenograms have been made to show the position and contour of the posterior portions of the diaphragm (fig. 5). By superimposing tracings from the preoperative and postoperative roentgenograms, it is possible to obtain a good comparison of the alteration in the thoracic cage, heart and diaphragm (figs. 3 and 6).

This roentgenologic evidence supplies ample proof that a marked reduction in thoracic volume occurs after an abdominal operation. Anything approaching physiologic aeration of a greater portion of the lower lobes during inspiration is impossible because of the position of the diaphragm and its diminished excursion.

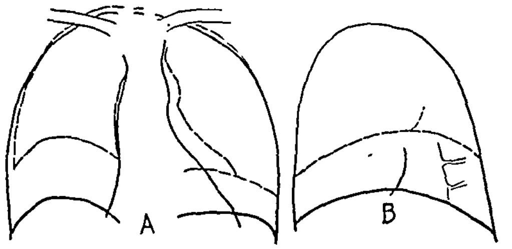

Fig. 3.—*A*, superimposed tracings of roentgenograms shown in figure 1. *B*, superimposed tracings of roentgenograms shown in figure 2. The broken lines indicate outline of thorax in roentgenogram made twenty-four hours after upper abdominal operation. Note position of diaphragm and heart in both the anteroposterior and the lateral views.

Several explanations for the altered position and restricted movement of the diaphragm are available. It is well known that distention of the abdominal viscera, splinting of the abdominal musculature because of pain, and surgical dressings are all factors. The disturbance of the normal pressure relationships in the immediate subdiaphragmatic region that occurs after opening the air-tight abdominal cavity must also be considered. The intraperitoneal pressure in the upper abdomen is subatmospheric.[9] I have demonstrated in animals an upward shift of the diaphragm by changing the intraperitoneal pressure from a subatmospheric, or negative, pressure to a positive pressure.[10] This alteration in pressure also diminishes the diaphragmatic excursions. The change in pressure was produced by two methods, either by the injection of small quantities of air intraperitoneally or by laparotomy (fig. 7). It is beyond the scope of this paper to discuss the factors above the diaphragm which might also play a rôle in this marked diaphragmatic displacement following laparotomy. From our observations there would seem to be a definite mechanical disturbance to respiration as a consequence of the admission of air into the peritoneal cavity.

A study of the vital capacity in 218 patients was made before and after the performance of abdominal operations. An ordinary clinical spirometer was used and the highest of three trials recorded. Records of patients who did not cooperate were discarded. Following operations on the upper abdomen, the vital capacity was reduced 64 per cent of the preoperative or normal value. Following lower abdominal operations, the average vital capacity was reduced 40 per cent of the normal value. In 106 of these patients, studies of vital capacity were made throughout the period of convalescence (fig. 9). The observations are in accord with those of Churchill and McNeil,[11] Head,[12] and Powers,[13] who found similar reductions in the vital capacity of patients after abdominal operations.

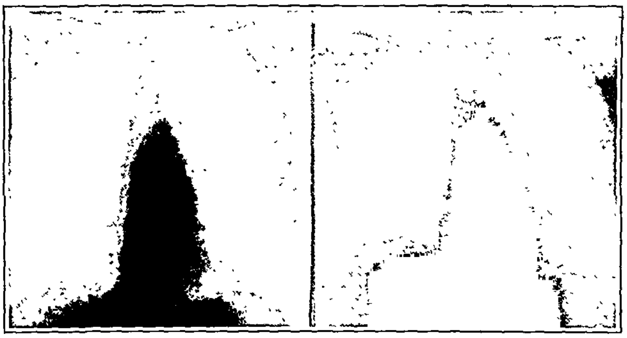

Fig. 4 (Mr. W. C.).—Bedside roentgenograms made before and twenty-four hours after a low abdominal incision was made for releasing peritoneal adhesions. Uniform position of patient, uniform distance and exposure. Examinations made at full inspiration. Note position of diaphragm, squat position of heart and decrease in thoracic volume.

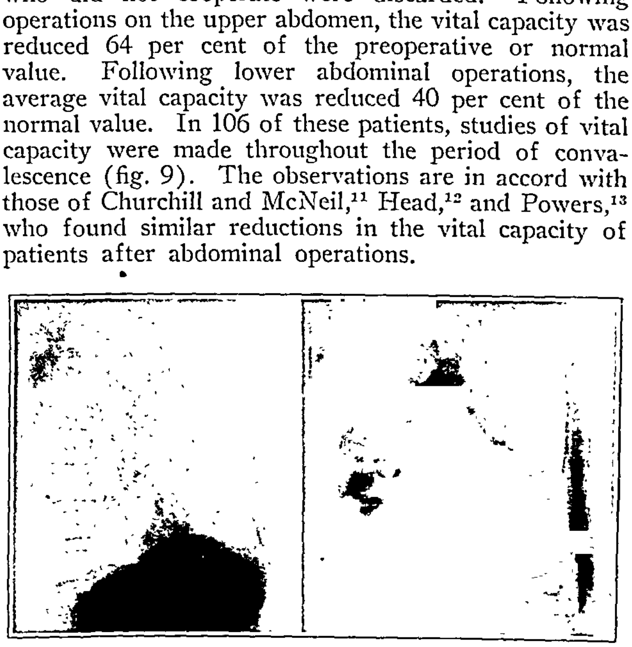

Fig. 5 (Mr. W. C.).—Lateral roentgenograms made before and twenty-four hours after a low abdominal operation. Note marked shift in position of the posterior portion of the diaphragm and obliteration of costophrenic angle posteriorly. The postoperative clinical course of this patient was uneventful.

Thoracic operations were not accompanied by such an extensive reduction of the vital capacity, which was low previous to operation. In twelve patients on whom a thoracoplasty was done or a mediastinal tumor removed, the average postoperative vital capacity was 72 per cent of the preoperative value. Head also found less variation in the vital capacity after thoracic operations.

All of the clinical and roentgenologic evidence in regard to the degree of postoperative pulmonary hypoventilation followed so closely the evaluation of the vital capacity that this test was used to determine the importance of various factors which influence respiratory action in the postoperative abdominal case. The relation of the position of the patient, the surgical dressing, the presence of pain, and the effect of the laparotomy itself without the pain factor were investigated.

The vital capacity of a large number of patients was taken in the semi-Fowler and horizontal positions. The bed position influenced the breathing little. The vital capacity was decreased less than 4 per cent in the horizontal position.

Determinations of vital capacity were made in seventy-nine patients before and after application of a muslin, many-tailed abdominal binder, and the results are given in the accompanying table. Only a slight reduction was noted in the preoperative group following the application of the binder. However, approximately a 15 per cent reduction in the vital capacity could be attributed to a tightly fitting abdominal binder, applied postoperatively. When an ordinary surgical dressing of gauze and adhesive tape was applied, very little change in the vital capacity was noted.

Vital Capacity Averages: Position and Dressing

	Number of Patients	Bed Position	
		Semi-Fowler, Cc.	Flat, Cc.
Preoperative	58	2,759	2,695
Postoperative	43	1,786	1,718
		Abdominal Binder	
		Before Application	After Application
Preoperative	54	2,740	2,661
Postoperative	25	1,798	1,520

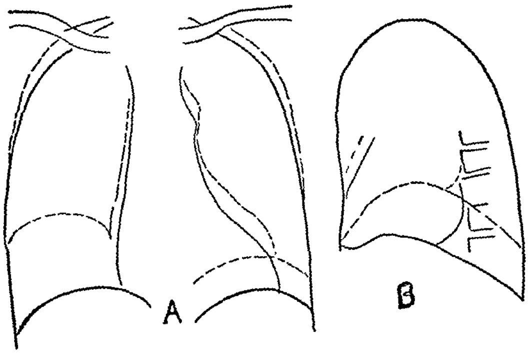

Fig. 6.—*A*, superimposed tracings of roentgenograms shown in figure 4. *B*, superimposed tracings of roentgenograms shown in figure 5. Dotted lines indicate outline of thorax in roentgenogram made twenty-four hours after a lower abdominal operation. Altered positions of diaphragm and heart are clearly shown. Note change in thoracic volume.

The effect of the partial abolition of pain by the administration of one-sixth grain (11 mg.) of morphine sulphate hypodermically was studied in thirty-five patients. The vital capacity was definitely greater thirty minutes after the administration of the drug (fig. 10). In ten patients the drug was administered both before and after operation and repeated determinations of the vital capacity were made and compared. A slight depression was noted in the preoperative patients, whereas postoperatively a definite improvement was noted.

The effect of pain in limiting respiration after operation was also investigated by studying patients still under the influence of spinal anesthesia. Vital capacity determinations were made: (1) with the patient on the operating table before the administration of the spinal anesthetic; (2) ten minutes after induction of spinal anesthesia by administration of from 100 to 200 mg. of procaine hydrobromide; (3) after the abdominal operation but before the return of cutaneous sensation, and (4) six hours later. The first reading served as a control while the second disclosed any alteration in vital capacity due to the spinal anesthesia itself. The third reading indicated the mechanical changes in respiratory activity due to the opening of the abdomen alone without the inhibiting effect of pain. The last reading taken after the disappearance of anesthesia indicated the extent of postoperative ventilation with all factors, including pain, being present. Records of noncooperative patients and those of patients with low blood pressure or intercostal paralysis were excluded. Satisfactory determinations were made in forty-one patients.

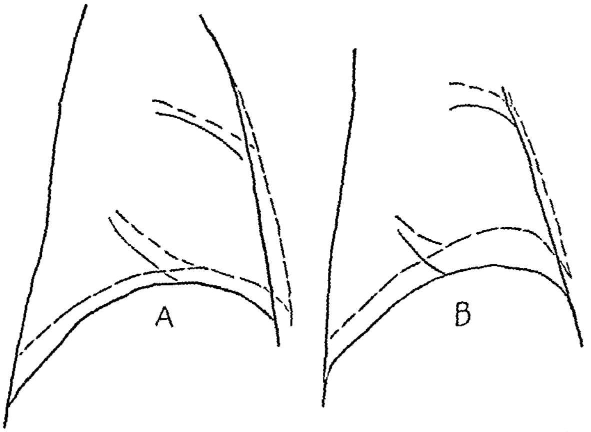

Fig. 7.—Superimposed tracings of lateral roentgenograms of two dogs anesthetized by a soluble barbital compound. All exposures made at full inspiration. *A*, dog 897: solid line indicates outline of thorax before 50 cc. of air per kilogram was injected intraperitoneally; dotted line indicates position after intraperitoneal air injection. *B*, dog 901: tracings made before and after laparotomy. Note high position of diaphragm and elevation of heart and costal arch in both animals.

Five patients on whom lower extremity or perineal operations were performed were used as controls. Vital capacity determinations were carried out in this group in a manner similar to that used in the abdominal group. In addition, a vital capacity reading was taken thirty minutes after the induction of anesthesia at the time the intercostal muscles were paralyzed. A fall in the vital capacity was noted while the intercostal muscles were not functioning, but a return to the normal level took place after the operation and after there had been a restoration of thoracic movements.

In the abdominal group a slight reduction in the vital capacity followed spinal anesthesia alone. The operation itself caused a marked fall in the vital capacity, even though the operation merely consisted of an exploratory laparotomy. After the disappearance of the effects of spinal anesthesia, a still greater reduction was noted (fig. 11).

From this study it would seem probable that a mechanical interference with respiration occurs at the time the abdomen is opened. This is confirmed by the experimental evidence, which demonstrates the fact that an elevation of intraperitoneal pressure, either by laparotomy or by injection of air, will cause an elevation of the diaphragm with restriction of diaphragmatic activity. Since the first measurement of vital capacity after operation was made at a time when the pain factor was absent, it seems justifiable to conclude that not all the faulty breathing after abdominal operations is due to pain. That pain is also an important factor cannot be denied. The further reduction in the vital capacity after the disappearance of anesthesia can be attributed to the splinting of the abdominal musculature because of pain.

All the evidence accumulated in our study of the postoperative pulmonary status of patients tends to show that the greatest single difference between the chest of the preoperative patient and the chest of the postoperative patient is a marked reduction in pulmonary ventilation. With the diaphragm elevated, the lower pulmonary lobes must necessarily retract and the contour and size of the bronchi suffer alteration. Faulty descent of the diaphragm prevents a proper interchange of air in the alveoli of the lower lobes and the movement of the air in the bronchioles is retarded if not actually stopped.

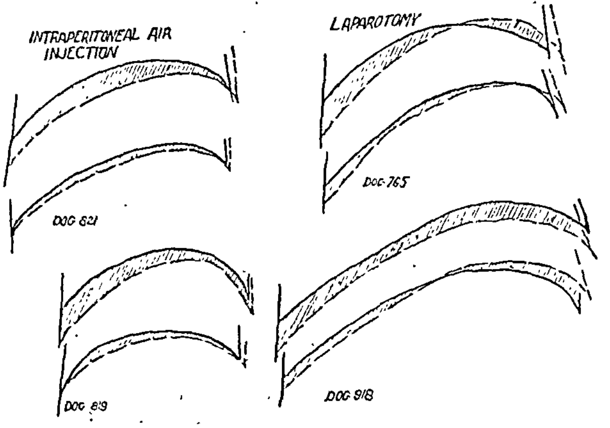

Fig. 8.—Tracings from fluoroscopic observations of diaphragmatic excursions in animals before and after a pneumoperitoneum had been produced either by intraperitoneal air injection or by laparotomy. The lower tracing of each animal indicates the extent of the excursion after the induction of a pneumoperitoneum. Note diminution of excursion.

Whether or not the poorly ventilated basal portions of the lung go on to complete atelectasis depends on the extent of the diaphragmatic elevation, the degree and duration of the hypoventilation, and other factors which might cause the complete closure of many of the smaller bronchi. Whether or not the postoperative patient with a poorly ventilated lung develops pneumonia depends on the presence of an infectious agent. However, since an extreme degree of hypoventilation can be demonstrated after every abdominal operation, it seems logical that primary consideration should be given to this factor, in any consideration of postoperative pulmonary complications. The administration of carbon dioxide, as suggested by Henderson and Haggard,[14] is the most effective method of increasing pulmonary ventilation. Its routine postoperative use has been proved valuable by Scott and Cutler,[15] Sise, Mason and Bogan,[16] Dzialoszynski[17] and others. In cases in which symptoms of hypoventilation are very evident, treatments with carbon dioxide are given at regular intervals for a period of three or four days postoperatively. Frequent turning and deep breathing exercises should be resorted to early in every case.

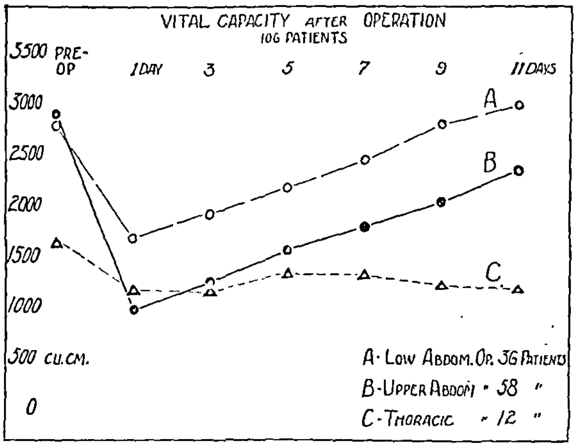

Fig. 9.—Average vital capacity measurements before operation and at two-day intervals after operation. Note extent of fall in vital capacity in the upper abdominal group. The gradual return toward the preoperative value is evident as the period of convalescence lengthens. The thoracic group had a low average preoperative vital capacity and this value was little influenced by operation.

My associates and I have been extremely interested in a method of restoring the intraperitoneal pressure to its normal subatmospheric status in order to prevent the elevation of the diaphragm and the consequent pulmonary involvement. Our clinical experience is too limited to warrant publishing results at this time. However, we wish to suggest a postoperative procedure that we are trying in an effort to overcome or shorten the duration of the mechanical disturbance of diaphragmatic activity following abdominal operations. With the abdomen open, the diaphragm is pulled farther within the thorax by the negative intrapleural pressure because other resisting forces have been removed. We attempt to force the diaphragm to a lower position and to reexpand basal portions of the lung as the abdomen is sealed. This is done by having the anesthetist give carbon dioxide inhalations under positive pressure as the abdomen is closed. Air in the abdominal cavity is displaced by physiologic solution of sodium chloride,

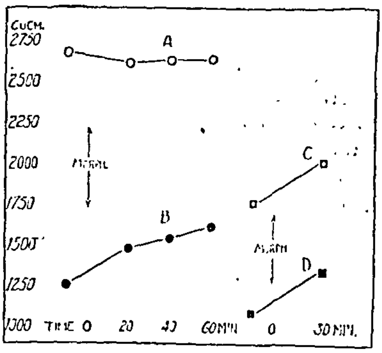

Fig. 10.—Effect of the administration of morphine on vital capacity. Group A represents the average vital capacity estimation in ten preoperative patients. Morphine slightly lowered the vital capacity. In the same patients after an abdominal operation, group B, the vital capacity was improved by morphine administration. Group C shows the average effect of morphine given to twenty-three patients after a low abdominal operation. Group D represents the effect in twelve patients after an upper abdominal operation.

and this is removed by suction when the peritoneum is finally closed. Absorption of air in the peritoneal cavity is slow, as roentgenograms taken from a week to ten days after laparotomy often show a film of air beneath the diaphragm. Water, however, gravitates to dependent portions of the abdominal cavity and, with sagging of the walls, tends to decrease the pressure in the subdiaphragmatic region.

Since it makes little difference in the vital capacity of patients whether the bed is flat or in the semi-Fowler position, it would seem wise to maintain the most comfortable position. If bronchial secretions are abundant, the foot of the bed should be raised at intervals to promote natural bronchial drainage. The ordinary surgical dressing restricts breathing little. However, a tightly fitting, many-tailed binder decreases the vital capacity and should not be used when there is pulmonary embarrassment.

The free postoperative use of morphine should be encouraged. Improvement in the vital capacity and an increase in freedom of respiratory effort were noticeable as the abdominal pain diminished. This is contrary to the belief of Jackson,[18] Bowen [19] and others, who, because of their fear of the loss of the cough reflex, warn against the use of morphine. We feel that the increased ventilation and increased ability to clear the throat which result from the decrease in pain far outweigh any objection to the postoperative use of morphine. Davis [20] found a distinct improvement in the arterial oxygen saturation in pneumonia cases when morphine was used to control pleuritic pains that were limiting respiratory excursions.

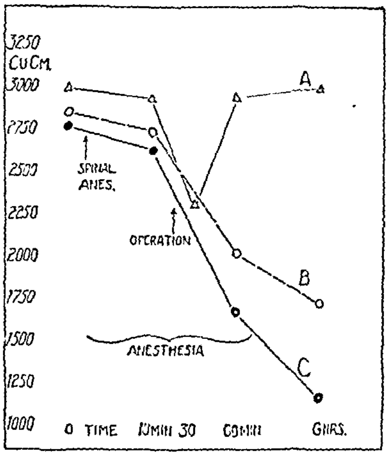

Fig. 11.—Effect of spinal anesthesia and operation on vital capacity. Group A, five patients in whom operation was on lower extremity. Group B, average vital capacity values in twenty-one patients on whom low abdominal operations were performed. Group C shows vital capacity values in twenty patients on whom upper abdominal operations were performed. Readings taken (1) before anesthesia; (2) after spinal anesthesia; (3) after operation while anesthesia is still present; (4) after operation after disappearance of anesthesia. Note marked fall in vital capacity in both abdominal groups, B and C, after operation, while anesthesia was still present and when pain was not a factor. Note further reduction in last reading when abdominal pain was present.

The routine use of the Roth-Barach oxygen chamber after abdominal operations has proved unnecessary. An increase in the percentage of oxygen in the inspired air decreases the amplitude of the respiratory excursions and therefore induces shallow breathing. We are at present carrying out a study of oxygen saturation of arterial and venous blood of patients before and after abdominal operations. The results so far obtained indicate that a fairly large proportion of these patients have a decrease in the arterial oxygen saturation. In patients that suffer from anoxemia, as evidenced by cyanosis, dyspnea and an increased rate of respiration that cannot be relieved by increasing pulmonary ventilation, oxygen therapy after operation is of distinct value. We use the oxygen chamber as routine procedure in all cases in which the condition has proceeded beyond one of hypoventilation; i. e., in cases of a bronchopneumonia.

SUMMARY

Evidence has been presented that a marked degree of pulmonary hypoventilation exists for a variable period of time after abdominal operations. Thoracic volume is decreased and expansion of the lower lobes is prevented by a high position of the diaphragm. A restriction of the diaphragmatic excursions contributes to the faulty aeration of basal portions of the lung. The opening of the abdominal cavity and the entrance of air permit the negative intrapleural pressure to draw the diaphragm higher in the thorax. Besides this mechanical factor, a reflex splinting of the abdominal musculature because of pain is also important in effecting the altered status of diaphragmatic activity after operation.

Rational postoperative treatment should include all measures that tend to overcome the faulty ventilation of the pulmonary tissue. Pain should be controlled by the adequate administration of morphine. A method of abdominal closure that will partially overcome pressure disturbances below the diaphragm is suggested.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. ALEXANDER AND BUCKINGHAM AND DR. OVERHOLT

Dr. **George P. Muller**, Philadelphia: In my cases of lung abscess, the duration of the disorder made little difference. Patients recovered who had had this condition for a year or a year and a half. Patients died in whom drainage had been done within three months of the onset. The virulence of the infection, the amount of partial gangrene of the lung that occurs, together with the extent in the more chronic case of the bronchiectasis and the age of the patient, will have a more important influence on mortality. It ought to be remembered that any chronic cough with putrid expectoration is not necessarily tuberculous. In my series, 42 per cent of the patients had had hemoptysis, many of them having been treated for a long time, even in sanatoriums, for tuberculosis. Also, proper emphasis was placed on the great value of recognizing a chronic suppurative sinusitis in these patients. As Graham said, in a number of instances he cured children with a suppurative disease of the lung simply by having their sinuses attended to. Drs. Alexander and Buckingham brought out the point directly that in suppurative disease of the lung one must proceed slowly and cautiously from the minor to the major procedure. Many of these patients are cured by rest and postural drainage, helped by an occasional bronchoscopy. Some are helped by phrenicectomy. Some have to come to external drainage, and those will be largely the patients with a cavity which does not drain into the bronchus, because, after all, what difference does it make whether a patient's lung drains into a bronchial tube or through an external opening, provided the cavity can be collapsed and the patient gets well? If there is a more diffuse process in the lung, involving an entire lobe, with a bronchiectasis, it is certain that simple drainage is ineffectual, and one then is forced to do a cauterization or lobectomy by exteriorization. I also think they made a good point in bringing out the fact that the modern treatment of a suppurative lung for drainage requires the removal of, say, three ribs. The simple removal of a rib and the cutting of a small hole and the putting in of drainage is not satisfactory.

Dr. **Carl R. Steinke**, Akron, Ohio: I want to emphasize the idea of not using artificial pneumothorax in lung abscesses. About the only location in which it could be properly used would be in the hilus type. Much safer would be the temporary interruption of the phrenic nerve. When I have wanted to compress the apex permanently, I have been using the method of turning up the periosteum of the second to the fourth ribs after resecting the ribs. It is well known that, in the production of pulmonary complications, hypoventilation or obstruction is nearly always essential. If the pneumococcus is present, pneumonia will develop. If mixed infection of staphylococci or anaerobes or sometimes streptococci are present, abscess or gangrene is apt to develop. In bronchiectasis, it is known that a good many cases are congenital, and the condition should be seen earlier if one expects to obtain good results surgically. The old chronic types are serious and require several operations, and sometimes operations are not beneficial. The stage operation in these conditions is essential. I have made it a practice, while sewing up the abdomen, to use 10 per cent carbon dioxide and 90 per cent oxygen for inhalation to procure increased ventilation. Since using this method I have reduced the number of cases with postoperative pulmonary complications. The lowered vital capacity is probably one of the main factors in the production of these conditions. Pulmonary complications following upper and lower abdominal operations are in about the same proportion as the difference in reduction of vital capacity in the upper and lower abdominal operations. In doing operations on the phrenic nerve, I have devised a stripper to use in certain cases. The open stripper is used when the nerve is crushed and I wish to tear off the accessory. The closed one can be used in phrenic exeresis. In doing operations on the chest with the patient on the side, I have devised an arm rest for taking care of the arm and forearm. The position of this rest can be changed to take care of the position of the patient on the table. The under rest is for the underarm when the physician wants it to come in front of the patient. Straps or towels should be placed around the arm to fix it in position.

THE USE OF MECHANICAL MEASURES IN THE TREATMENT OF OBSTINATE EDEMA *

EDWARD F. BLAND, M.D.
AND
PAUL D. WHITE, M.D.
BOSTON

The treatment of severe and refractory edema of the lower extremities has occupied the attention of physicians for many centuries. The celebrated Roman philosopher Celsus,[1] of the first century A. D., in a chapter on "De Hydropicis," called attention to the beneficial effects of a low fluid intake as well as to the increased elimination of fluid by excessive sweating; but in addition to these measures it is of considerable interest to find the following recommendation given by him for the treatment of dropsy: "Above all an incision ought to be made, of almost four fingerbreadths, on the inner side [of the leg], from which much fluid may drain for several days." Although even today this original recommendation of Celsus is occasionally resorted to, more appropriate measures are now available.

Great progress has been made during the last fifty years in the direction of a better understanding of cardiac and renal disease. The realization of the importance and of the rational use of digitalis in patients with early congestive failure, the introduction of the caffeine diuretics, and more recently of merbaphen (novasurol) and mersalyl (salyrgan), have proved very efficacious in the prevention and control of anasarca. However, in spite of these measures, a case of extreme edema is occasionally encountered that resists all efforts at medical control. It is this type of case that we shall consider here, calling attention to the numerous procedures that have been employed for combating such a distressing situation, in particular one which, although introduced more than fifty years ago by Reginald Southey,[2] has largely been forgotten. We believe that this measure proposed by Southey has a definite place in the treatment of patients with obstinate edema.

By the mechanical removal of considerable quantities of excessive edema fluid, one may hope to accomplish a threefold purpose: in the first place, by reducing the size of the distended parts, the patient is made more comfortable; secondly, the already overtaxed and failing circulatory system is relieved of an additional burden; and, finally, the partial removal of what has been called by Galli [3] the "peripheral barrier" to the circulation favors a more adequate resorption of the remaining fluid by subcutaneous veins and lymphatics when these have been embarrassed by the pressure of the edema fluid.

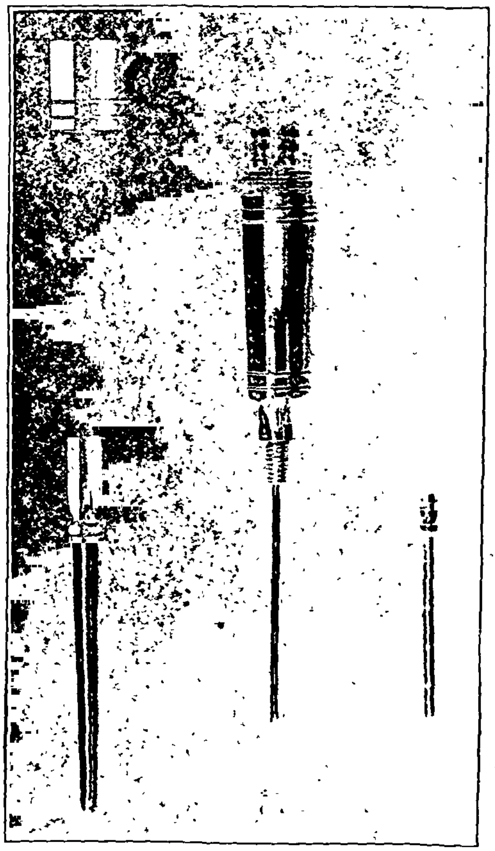

Fig. 1.—Southey's trocar and cannulas, actual size. In the handle of the trocar is a compartment in which four cannulas are carried.

Of the local measures that have been employed in the treatment of edema in general, we shall discuss briefly the ones that to us seem of greater interest. They fall into three groups:

1. In relatively slight edemas, such mechanical procedures as gentle massage and elevation of the part lessen the tension, make the patient more comfortable,

and promote the absorption of the excess fluid. These measures, in addition to medical treatment, are usually sufficient to control the situation.

2. The application of hypertonic solutions, usually a dressing containing a solution of sodium chloride in glycerin, has been employed and recommended by Carnot,[4] *provided the skin is intact. Edematous legs are said to shrink several centimeters in twenty-four hours.* We have not attempted this, as it has appeared impracticable to us.

3. In the presence of a large amount of fluid, several surgical measures for its evacuation are available:

(*a*) Acupuncture, in which multiple small needle pricks are made into the edematous parts, thereby permitting fluid to exude for several days, has been widely practiced during the past century, and striking relief has been noted in numerous patients following the drainage of considerable amounts of fluid. However, as has been pointed out by others, all who have used this method are acquainted with the serious drawbacks attending ordinary puncture of the distended limbs. The fluid that drains away is difficult to collect and to control. The patient's skin is constantly exposed to an irritating and decomposing body fluid, which promotes infection and ulceration; erysipelas sometimes follows, may accelerate the patient's death and greatly increase the suffering of the last few days of life, while the constant wetting of the bedclothes keeps the patient damp and cold, and is an undesirable feature.

(*b*) Long, deep incisions have been employed by others and by this method as much as 30 liters of fluid is said to have been obtained in twenty-four hours.[5] In 1927, Sépet[6] used this procedure on fourteen patients and reported excellent results in all cases with the evacuation of much fluid, regression of the edema, increased urination and improved cardiac action. It would seem, however, that except in rare cases this procedure is undesirable and that it may be attended by some danger to the patient. Rarely, in the past, even more heroic measures have been attempted, such as that recorded by Finch[7] in 1823 in a "case of anasarca in which amputation was successfully employed, and the fluid discharged by it."

(*c*) Finally, what appears to us the simplest, safest and most desirable method of treating obstinate edema of considerable degree is the one originally recommended by Southey. Although it is frequently mentioned in textbooks and occasionally in the literature, we have reason to believe that its value is not generally appreciated, and certainly not in America.

In 1877, Reginald Southey, a physician of St. Bartholomew's Hospital in London, realizing the limitations and dangers of the procedures previously employed, perfected a method of subcutaneous drainage by means of small capillary tubes which are shown in figure 1 and which bear his name. The apparatus is simple in design and consists of a small metal trocar and cannula, the latter containing several lateral perforations permitting a free flow of fluid. In the handle of the trocar is a compartment in which additional cannulas are carried. The use of the instrument is not difficult. The skin at the sites selected for insertion, usually the outer and inner aspects of the lower parts of the legs, the dorsum of the feet, or the scrotum, is cleansed aseptically, a wheal is made with procaine hydrochloride, and a small amount of sterile ointment is applied to prevent local irritation. The trocar and cannula are inserted deeply into the swollen part; the cuff of the cannula is held firmly with a clamp while the trocar is withdrawn and a small rubber tube attached.[8] *Fluid wells up immediately and continues* to flow in steady drops from the cannula until the rubber tube is in place; this, in turn, is led off to a suitable receptacle placed beneath the bed for the collection of the fluid. As many tubes may be used as seem desirable; we have found that two in each leg are usually adequate; they are left in place for from one to several days and cause surprisingly little discomfort to the patient. *There is ordinarily no leakage about the cannula*; the skin and dressing remain dry. Since the flow is constantly away from the site of insertion, the chance of infection is greatly lessened, *and with an ordinary* amount of care we believe that it is relatively slight. Following the removal of the tubes, a moderate amount of fluid may continue to drain for a few days, but the wounds heal without difficulty. Curshmann[9] has designed a larger trocar and cannula *to be used in the same fashion* as Southey's apparatus, but it appears that in the majority of cases, certainly, the latter is adequate.

TABLE 1.—*Cases in Which Southey's Tubes Were Used*

Patient and Age	Diagnosis	Duration of Edema	Result of Withdrawal of Fluid in Reducing Size of Legs or Scrotum	Amount of Fluid Withdrawn, Cc.	Time During Which Fluid Was Removed	Condition of Patient
1. M. C. 63	Hypertensive heart disease	6 mo.	+++	16,000	2 days	Died of bronchopneumonia one month later
2. F. J. 48	Hypertensive and rheumatic heart disease	3 mo.	+++	9,000 3,000	3½ days 1 day	Died of bronchopneumonia one month later
3. E. C. 49	Hypertensive and rheumatic heart disease	12 mo.	++	2,000 (scrotum)	1 day	Living six months later
4. M. L. 44	Hypertensive heart disease	3 mo.	++	3,000	24 hours	Left hospital against advice not traced
5. M. W. 29	Rheumatic heart disease	30 mo.	++	3,000 1,900	24 hours 2 days	Died of heart failure two weeks later
6. R. C. 52	Hypertensive heart disease	4 mo.	+	1,600	2½ days	Died of bronchopneumonia two weeks later
7. N. G. 56	Hypertensive and coronary heart disease	2 mo.	0	500	? hours	Died of congestive heart failure two weeks later
8. H. A. 77	Abdominal carcinomatosis	2 mo.	0	500	3 hours	Died four hours later

During a recent visit of one of us to the clinic of Sir Thomas Lewis in London our attention was directed, by observation of a certain case, to the excellent results that occasionally may be obtained by the employment of this procedure; 6 liters of edema fluid were removed from the legs by Southey's tubes in three days with great symptomatic relief and objective evidence of improvement. The patient was a young woman with severe rheumatic heart disease, normal rhythm, and congestive failure with extensive anasarca.

We have encountered in the course of the past ten months in Boston eight cases of extensive edema, several of which failed to respond adequately to medical treatment, and in these cases we have employed Southey's tubes in an attempt to relieve the anasarca.[10] In seven of the cases the edema was the result of congestive heart failure, and in one case it was secondary to an extensive abdominal carcinomatosis. The results are shown in table 1.

REPORT OF CASES

Case 1.—M. C. (private patient), a man, aged 63, a foreman seen in consultation, had had cardiac asthma for the previous four years; he had been much worse during the last year. For six months he had had edema of the legs which responded to digitalis and merbaphen, but for the past two and one-half months the edema had been reaccumulating, involving the lower extremities, the genitalia and the abdominal wall. Urination had been difficult because of an enlarged prostate and enormous swelling of the scrotum and penis, and frequent catheterization had to be resorted to. On physical examination his heart was found to be very large, auricular fibrillation was present, but the rate was well controlled by digitalis. The blood pressure was 175 mm. of mercury systolic and 100 mm. diastolic. Massive edema of the lower extremities and of the genitalia was present. A diagnosis of hypertensive heart disease with auricular fibrillation and congestive failure was made. Southey's tubes were inserted, two in the dorsum of the right foot, two in the left foot; later, one of those in the right foot was transferred to the scrotum. They were allowed to remain in place two days, and at the end of that time 16 liters of fluid had been collected; of this amount 1 liter had been removed from the scrotum. The patient was greatly relieved and was able to lie flat in bed with considerable comfort, a position which had been impossible before this time. During the course of the next two weeks the edema slowly reappeared; the tubes were again inserted and in twelve hours 2 liters of fluid was drained from the legs; at the end of this time the patient fell from a chair and the tubes were pulled out; the legs were quite soft and therefore the tubes were not replaced. The patient lived a month longer and up to the time of his death there had been very little reaccumulation of the fluid. The relief afforded in this case by the mechanical removal of the fluid (36 pounds, or 16.3 Kg.) was the most striking in our series and almost certainly postponed the fatal termination by several weeks.

Case 2.—F. J. (Massachusetts General Hospital), an American housewife, aged 48, who was known to have had hypertension and rheumatic heart disease for sixteen years, entered the hospital because of edema, dyspnea and attacks of precordial pain, anginal in character, for the preceding two months. She also had mild diabetes, which was easily controlled by diet. On examination she showed evidence of rheumatic and hypertensive heart disease with mitral stenosis and regurgitation and congestive failure with normal rhythm. During the course of several weeks of bed rest, digitalization and administration of diuretics she improved considerably, but slight edema persisted. She was permitted to go to a convalescent home, where in spite of daily digitalis and bed care the edema gradually returned, so that in a few weeks she returned to the hospital with marked congestive failure, massive edema of the legs, edema of the abdominal wall and slight ascites. After a week's trial with diuretics there was no subsidence of the edema. Southey's tubes were inserted and in three and one-half days 9 liters of fluid was withdrawn, which resulted in considerable improvement, subjectively and objectively, with the loss of most of the edema of the body wall and legs. It is of some interest that during the first twenty-four hours there was no change in the size of the legs, but the edema of the body wall decreased considerably. After three and one-half days the tubes were removed; with mersalyl intravenously the anasarca was partially controlled, but it slowly returned during the next three weeks. Although the edema was of only moderate degree, the patient asked that the tubes be reinserted because of the relief obtained from them in the first instance. This was done and 3 liters of fluid was withdrawn, with considerable decrease in the size of the legs. One week later the patient died of bronchopneumonia.

Case 3.—E. C. (private patient of Dr. L. M. Hurxthal), a man, aged 49, entered the Deaconess hospital, Boston, in June, 1928, because of dyspnea, gaseous distention and edema of the legs of about six weeks' duration. He had had rheumatic fever at 21. Physical examination revealed fluid in the chest, considerable edema of the lower legs, and abdominal distention. The heart was very large; the rhythm was absolutely irregular at a rate of about 120. At the apex was a rough systolic murmur. The blood pressure was 200 mm. of mercury systolic and 120 mm. diastolic. A diagnosis was made of hypertensive and rheumatic heart disease with auricular fibrillation and congestive failure. The patient had been overdigitalized and on withdrawal of the drug and the administration of theophylline (theocin) considerable improvement followed. He was readmitted to the hospital in November, 1928, and again in January, 1929, because of recurring and extensive edema. On each occasion the edema subsided following the administration of mersalyl. In December, 1929, he again entered the hospital with moderate edema of the lower legs, a tremendously swollen scrotum (size of a football) and ascites. After the removal of 4 liters of fluid from the abdomen, a single Southey's tube was inserted into the scrotum and at the end of twelve hours 1,200 cc. of fluid had been drained away with marked symptomatic relief to the patient. A Curshmann tube was then inserted also and 800 cc. of additional fluid was removed, so that at the end of twenty-four hours 2 liters of fluid had been collected and the size of the scrotum had receded almost to normal. The edema of the legs subsided following the use of mersalyl and theophylline. In March, 1930, the patient entered the hospital for the fourth time because of tremendous anasarca. The veins in his arms had become thrombosed as the result of numerous previous injections and the response to mersalyl administered intramuscularly was inadequate, so that an incision was made in one thigh from 3 to 4 cm. in length and down to the deep

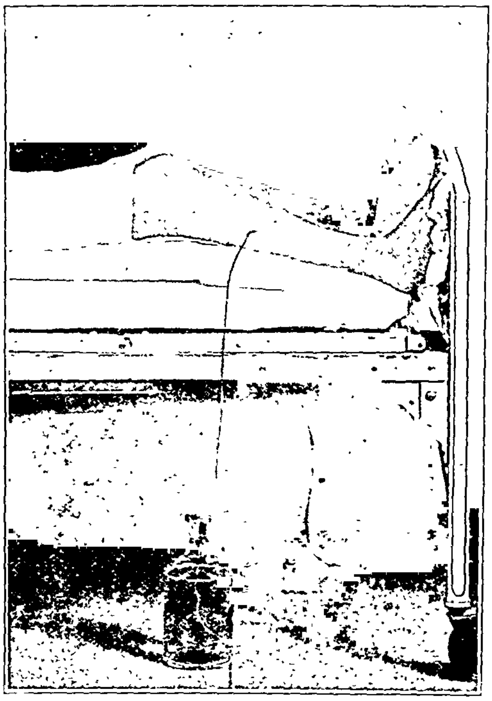

Fig. 2.—Southey's tubes in use.

---

[10] One of these patients (case 3 of the table), in the practice of Dr. L. M. Hurxthal, was treated by him with the insertion of Southey's tubes. We are indebted to him for permission to include this case in our series.

fascia, from which 30 pounds (13.6 Kg.) of edema fluid drained away during the following two weeks. Although still alive, the patient is in poor condition and the anasarca is returning.

Case 4.—M. L. (Massachusetts General Hospital), a Polish housewife, aged 44, entered the hospital because of intermittent aching precordial pain, dyspnea, and orthopnea for the preceding five months. For the past three months she had been confined to bed because of the symptoms mentioned and because of edema of the lower extremities. In spite of digitalis she became progressively worse, until at the time of entry she was orthopneic and cyanotic. The heart was very large with normal rhythm and a rate of 100. The sounds were of poor quality. The blood pressure was 150 mm. of mercury systolic and 110 mm. diastolic. There was evidence of marked congestive failure with ascites, massive pitting edema of the legs, and moderate edema of the hands and arms. The electrocardiogram showed right bundle branch block. A diagnosis of hypertensive heart disease with congestive failure was made. An abdominal paracentesis yielded 1,200 cc. of ascitic fluid. Southey's tubes were inserted, two in each leg, and 3 liters of fluid was collected in twenty-four hours, with a definite decrease in the size of the legs. The patient spoke little English, was difficult to manage, and because she repeatedly pulled out the tubes it was decided at the end of the first twenty-four hours not to replace them. The foregoing treatment was followed by the administration of ammonium chloride, mersalyl and theobromine. During her three weeks' stay in the hospital she lost 27 pounds (12.2 Kg.), largely as a result of the subsidence of edema. The patient was considerably improved, but left the hospital against advice, and we have no further information concerning her. In this case, because of her critical condition and acute discomfort on admission, it was thought best to attempt relief of the edema by mechanical methods immediately, rather than to await the slower results to be expected from the use of diuretics; the rapid improvement was gratifying.

Case 5.—M. W. (Massachusetts General Hospital), a housewife, aged 29, entered the hospital with rheumatic heart disease, mitral stenosis and regurgitation, and auricular fibrillation with marked congestive failure. In spite of digitalis and diuretics she had been bedridden for two and one-half years with the development of generalized edema of the extremities, chest wall and face, together with ascites. Because of the slowly increasing edema she was recommended for admission to the hospital. Digitalis and mersalyl had little effect on the anasarca. Two of Southey's tubes were inserted into each thigh and at the end of twenty-four hours 3 liters of edema fluid had been collected, and at the end of three days 5 liters had drained away and the extremities had shrunk to almost normal size, although considerable edema of the body wall remained. The tubes were removed. The edema of the legs did not reaccumulate up to the time of the patient's death from cardiac failure two weeks after the therapy outlined.

Case 6.—R. C. (Massachusetts General Hospital), an Italian housewife, aged 52, entered the hospital with severe congestive heart failure. Five years previously she had been told that she had high blood pressure and heart disease, and because of dyspnea on exertion she was started on digitalis therapy, which had been continued to the present time. Her reserve gradually diminished, so that one year prior to entry she had to stop work because of symptoms of dyspnea and mild substernal oppression. Four months before entry edema of the ankles appeared which became progressively worse. On admission to the hospital she was dyspneic, orthopneic and slightly cyanotic. The heart was markedly enlarged in all diameters; a well marked gallop rhythm was present at a rate of 110. The blood pressure was 230 mm. of mercury systolic and 160 mm. diastolic. There was moisture at both lung bases, the abdomen was distended with fluid, and there was marked edema of the lower extremities and papilledema of both optic disks. The urine showed a slight trace of albumin. A diagnosis of hypertensive heart disease and congestive failure was made. Digitalis was increased to 4½ grains (0.3 Gm.) a day. The removal of 1,250 cc. of fluid from the abdomen gave considerable relief to respiration. Southey's tubes were inserted and during the course of two and one-half days 1,600 cc. of fluid was withdrawn; the skin of the legs was considerably less tense and the patient was more comfortable. The anasarca was well controlled by digitalis and diuretics, but the patient went slowly downhill and died at the end of two weeks of bronchopneumonia.

Case 7.—N. G. (private patient), a grocer, aged 56, seen in consultation, had had severe angina pectoris for three years and for the past two months attacks of cardiac asthma, dyspnea on slight exertion, and increasing edema of the extremities in spite of digitalis and mersalyl. On physical examination he was found to have a very large heart, normal rhythm, pulsus alternans, and evidence of marked congestive failure. The blood pressure was 185 mm. of mercury systolic and 120 mm. diastolic. The edema was extensive. Southey's tubes were inserted but were kept in place with difficulty. A superficial infection developed and it was thought best to discontinue the use of the tubes; only 500 cc. of fluid was obtained. The patient was not relieved, went progressively downhill, and died a few weeks later with marked congestive failure.

Case 8.—H. A. (Massachusetts General Hospital), a factory worker, aged 77, entered the hospital because of abdominal pain, loss of appetite, frequency of urination, and swelling of the legs for two months, becoming progressively worse. On admission he was found to be emaciated and uncomfortable in all positions. There was no edema of the scrotum, and no abdominal fluid could be demonstrated. There was a questionable mass in the epigastrium, thought to be the stomach. The heart was considered normal for a man of his age. His condition was critical; although a definite diagnosis was not possible, abdominal carcinomatosis was felt to be most likely. Because of the marked edema, Southey's tubes were inserted and 500 cc. of fluid was obtained in three hours, without noticeable relief of the tension of the legs. The patient being practically moribund, the tubes were removed, and he died one hour later. Carcinoma of the pancreas, with metastases to the liver and peritoneum, was found at postmortem examination.

Table 2.—*Analysis of Edema Fluid and Comparison With That of Blood Serum and Normal Cerebrospinal Fluid*

	Blood Serum	Edema Fluid	Normal Values for Cerebrospinal Fluid (Ayer and Fremont-Smith)
Case 4			
Sodium, mg. per 100 cc.	328	321	
Chloride (as NaCl), mg. per 100 cc.	514	570	720-750
Nonprotein nitrogen, mg. per 100 cc.	24	23	12-18
Total protein, Gm. per 100 cc.	6.97	0.695	0.10-0.45
Total solids, Gm. per 100 cc.	8.64	1.60	
Sugar, mg. per 100 cc.	98	93	50-75
Case 6			
Sodium, mg. per 100 cc.	313	320	
Chloride (as NaCl), mg. per 100 cc.	553	627	
Nonprotein nitrogen, mg. per 100 cc.	33	27	
Total protein, Gm. per 100 cc.	5.95	0.407	
Total solids, Gm. per 100 cc.	7.82	1.35	

COMMENT

The fluid from two of our patients has been analyzed and compared with an analysis of the patients' blood serum by Dr. Frank Fremont-Smith, who finds that it resembles fairly closely cerebrospinal fluid, except for the higher protein content and the lower chloride content which go hand in hand (table 2).

It will be seen from these cases that one patient did not live a sufficient length of time to give the method an adequate trial. Of the remaining seven patients, one was not relieved and the use of the tubes resulted in a superficial infection which made the patient even more uncomfortable for several days but did not affect the ultimate prognosis. One patient was slightly improved until death two weeks later from bronchopneumonia; five patients were definitely relieved so far as the edema was concerned, and the results in two of these cases were striking. From the nature of the cases selected for this procedure ultimate recovery is anticipated in only a small percentage; however, the mechanical removal of the excessive fluid may be a means of sparing the patient great discomfort, and occasionally it may even postpone indefinitely a fatal termination.

Others have used somewhat similar methods with successful results. DeStéfano[11] has employed direct drainage by means of small platinum needles under the skin, and in his hands this method has proved effective and harmless in 100 cases. In one of his patients 27 liters was evacuated in forty-eight hours; in only one case was there a slight superficial infection, which subsided in the course of twenty-four hours.

SUMMARY AND CONCLUSIONS

1. In eight cases of extensive edema, mostly the result of congestive heart failure and resistant to medical therapeutic measures, we have employed Southey's tubes inserted into the edematous subcutaneous tissue of the legs or scrotum. In two of our patients the results were strikingly beneficial, following the removal of 16 liters in the course of two days in one case, and of 9 liters in three and one-half days in another. In three patients there was moderate relief; in one case only slight improvement was noted; the remaining two patients were not relieved.

2. In suitable cases the use of Southey's tubes is a valuable therapeutic procedure, and we believe that the employment of this method as recommended many years ago by Reginald Southey should be revived.

ABSTRACT OF DISCUSSION

Dr. F. Janney Smith, Detroit: There is unanimity of opinion that hydrothorax, if extensive, should be tapped as the opening move in the treatment of myocardial insufficiency; likewise that ascites, if responsible for a tense abdomen, elevated diaphragm and respiratory embarrassment, should be drained in a similar manner. But the mechanical removal of fluid from the lower extremities by means of Southey's tubes has, for the most part, been placed on the medical museum shelf. In part, this has been due to the increase in our resources in the treatment of edema of cardiac origin, to the development of newer and efficient diuretic drugs, to the increasing use of the high carbohydrate diet in treating the water-logged cardiac patient, and to the general improvement in our knowledge of how to treat congestive cardiac failures as a whole. Again, the management of surgical incisions or punctures in the edematous lower extremities requires the utmost aseptic precautions and aftercare; and the practitioner prefers not to risk the development of a cellulitis with its obvious association with such punctures or incisions. And now Dr. White is taking these medical antiques down from the shelf and putting them rightly back into practical use again. However, in the introduction of Southey's tubes or a suitable trocar into the subcutaneous tissue of the leg and in leaving such tubes in situ, although, owing largely to the steady outflow of edema, secondary infection does not often occur, it is a real danger whenever a foreign body is left in the tissues and is continuous with the outside world. I would therefore suggest that, in those cases in which marked and obstinate edema of the lower extremities and genitalia indicates mechanical removal of fluid from the lower extremities, acupuncture may be tried before resorting to Southey's tubes, or if Southey's tubes are not readily available. It would seem that the main advantage of Southey's tubes, after all, perhaps lies in the ability to collect and accurately measure the fluid obtained and the avoiding of soaking the bed and dressings. But if careful aseptic precautions are taken and bulky dressings used, acupuncture can be carried out, making use of an 18-gage needle, making perhaps six or more punctures in either extremity. Owing to the roundness of the puncture wound and the outflow of edema, these may remain open for days and large volumes of fluid can be obtained in this way. The use of deep incisions into the edematous lower extremity is objectionable because of the great probability of secondary infection.

Dr. Arthur C. Morgan, Philadelphia: In a teaching experience of more than thirty years, I have been continuously using Southey's tubes. I should like to call attention to one or two points in respect to Southey's tubes. The tube itself should be made of silver and not of aluminum. Silver has chemotactic power in repelling invasion of micro-organisms. It is perfectly safe to introduce these needles or the cannulas into the edematous tissue, allowing the needles to remain for several days without infection occurring from them. Sometimes, however, because of the devitalized condition of the tissues, a cellulitis, rather than erysipelas, may develop, and this can easily be controlled by removing the needles and then treating in an aseptic manner the local sore that is present. The stem of the needle itself must be well made so that it will not bend or break. Having many perforations in the cannula instead of one in the distal end is important. Usually eight are found in all instruments now on the market. That permits drainage by capillary oozing and seeping to the external surface. Instead of using the rubber tubing, I wrap ordinary gauze bandages around the leg and put a piece of oil cloth down on the floor, or a rubber mat on the bed, and then an old blanket to absorb the fluid. With these patients sitting in a chair, with the feet dependent, all I do is to get a child's bathtub, have the blanket put inside and let them drain. I have seen gallons come out in that way. I have seen edema of the hands likewise much benefited because of the insertion of the needles in the legs. The advantage of the Southey tube is that the kidneys or the bowels do not have to remove the extraneous fluid. Digitalis or any other blood pressure raising drug is not needed to carry off this extraneous fluid. I would emphasize that this will not apply to the relief of edematous tissue from inflammation. It must be hydrostatic fluid.

Dr. Edward F. Bland, Boston: We have felt that these tubes have a distinct advantage over the usual methods; namely, that the patient is able to lie in bed with relative comfort without being inundated by the fluid necessarily drained into the bed from other methods of attack. The ease with which infection may occur is greatly lessened since the capillary flow is constantly away from the point at which the needles are inserted. A slight infection occurred in one case, a patient who was irrational, difficult to manage, and treated outside the hospital. In this case the tubes came out on several occasions and were replaced by the attendant. In none of our other cases have we had a case of infection. In the series of 100 cases reported by De Stéfano treated in this manner in only one was there a slight superficial infection.

Lavoisier.—The modern era of the science of nutrition was opened by Lavoisier in 1780. He was the first to apply the balance and the thermometer to the investigation of the phenomena of life, and he declared "La vie est une fonction chimique." The work of today is but the continuation of that done a century and more ago. Lavoisier and Laplace made experiments on animal heat and respiration. The great German chemist Liebig received his early training in Paris, residing there in 1822. Liebig's conception of the processes of nutrition fired the genius of Voit to the painstaking researches which laid the foundation of his Munich school. These have been repeated and extended by his pupils, of whom Rubner is chief, and by others the world over. Thus the knowledge often transmitted personally from the master to the pupil, to be in turn elaborated, had its seed in the intellect of Lavoisier. It was he who first discovered the true importance of oxygen gas, to which he gave its present name. He declared that life processes were those of oxidation, with the resulting elimination of heat. He believed that oxygen was the cause of decomposition of a fluid brought to the lungs, and that hydrogen and carbon were produced in this fluid and then united with oxygen to form water and carbon dioxide.—Lusk, Graham: Elements of the Science of Nutrition, Philadelphia, W. B. Saunders Company, 1928.

INTRACAPSULAR FRACTURES OF THE NECK OF THE FEMUR *

JOHN J. MOORHEAD, M.D.
NEW YORK

Inherently we, as traumatic surgeons, recognize that in the management of intracapsular fractures of the neck of the femur we are circumstanced by two major problems not encountered in any other fracture: the age incidence and the structural incidence.

First, the age incidence, because the vast majority of patients are in or beyond the fifth decade. Shaft fractures of the upper extremities and some of the lower extremities in this age group do not dismay us, because the enforced recumbency is less absolute and less prolonged. We long have recognized the need for early mobilization in all types of fractures, especially in the articular group. Yet, despite this clinical edict, we have continued to immobilize hip fractures, thus disregarding the lessons learned and practiced in other joint fractures. Further, in hip fractures, as in no others, immobilization induces local and general stasis in the joint with the poorest local circulation and in the person with the poorest general circulation.

Second, the structural incidence, for in many of these cases, utter failure to repair is noted because of absorption of the narrow part of the neck. There is in this area a quadrilateral segment which seems to resist bone regeneration even though the original reduction has been entirely adequate, the splintage efficient and the after-care exacting.

Many explanations are offered for this distressing failure, often inexplicable in view of the early promise of recovery. None of these explanations are wholly satisfactory, and again we are reminded that the traumas, like pathologic processes elsewhere, can be listed in three prognostic groups:

A. Recovery without definitive treatment.
B. Recovery with definitive treatment.
C. *Failure with or without definitive treatment.*

The first of these get well no matter what is done; the second get well depending on what is done; the third do not get well whatever is done.

My belief is that many in this neck of the femur group fall into the third or failure class, and the contrast between them and the base of the neck group is so striking that clinically the latter can be regarded as high fractures of the shaft with a corresponding prognosis. There is probably no fracture in which failure is more frequent than in this zone, and surely there is no other fracture so surrounded by pessimism even from the days of Hippocrates. For a long time union of any sort was denied; then fibrous union was admitted, and now the accepted view is that bony union is obtained often enough to warrant the attempt. It must always be remembered, however, that our present attitude of optimism must accord with the physique of the patient and the physics of the lesion. We are dealing usually with poor material systemically and locally, and hence guard the prognosis.

REASONS FOR FAILURE

The structural incidence has been mentioned. We are told that this quadrilateral area ("calcar femorale") is cancellous and we remind ourselves that similar bone elsewhere repairs feebly. Witness the os calcis, the body of the vertebra, the lower end of the radius.

The blood supply of the femoral neck is easily compromised by the fracture in question, and when thus affected there is the unusual situation of a small section of bone robbed of vitality, contained in a vacuum, bathed in a mixture of blood, serum and synovia, at body temperature. Under the circumstances, is it any wonder that this fragmented cancellous bone literally stews in its own juice, digests and then absorbs? This virtually resembles an attempt to perform a spontaneous reconstruction operation by bringing the outer section of the neck against the head of the bone.

It is said also that the nutrient vessels of the neck of this bone are atheromatous or become readily plugged and thus ischemia and ultimate local death ensue. We know that this occurs in other areas when reduction is adequate, as, for example, in the lower third of the tibia, a zone which in my experience ranks first as to nonunion. It is said also that calcium or phosphorus deficiency is a factor. I have not found it so in this or any other fracture.

Endocrine disturbance, the presence of other diseases and general inanition are factors of no proved value in explaining why in the one case union occurs and in another no union.

To me the basic factor of nonunion in any fracture is failure of coaptation due to interposition of soft or hard parts. In other words, there is a group that starts with a spontaneous arthroplasty because of the interposition of tissues incidental to the fracture itself or the management of it. A skin wound fails of primary union unless coaptation is adequate, and I am quite sure that a bone wound (a fracture) acts likewise.

As explanatory, then, of nonunion in this hip group, it may be said that we are dealing with an area of known poor repute in which fragments of bone and perhaps frayed capsule and iliopsoas are acting as interposition factors. Certain it is that there must be some determining elements in some of these fractures to cause nonunion, the absence of which means union.

If, then, we agree in believing that every fracture of this sort is a potential hazard, it is the part of prudence to adapt our therapy accordingly.

THE TREATMENT

Hip cases may be divided clinically into three grades of physique: the A or good grade, B the fair grade, and C the poor grade. This accords with the classification in other traumapathies wherein an attempt is made to repair in terms of the kind of material that there is to work with. Obviously an arteriosclerotic patient of 70 is not a good surgical risk from any standpoint; but the fallacy of gaging by the calendar rather than by the condition is well known. A case in point is an intracapsular fracture in a patient, aged 92, who was a better risk than many others aged 50 or less.

I saw in consultation a type 2 intertrochanteric fracture in a patient, aged 102. The point at issue was the safety of allowing her out of bed, and on her first day of freedom she sat up seven hours.

In passing, let me revert to what I call the "wren" type of patient, who will easily be recognized. Usually it is grandmother, aged about three score and ten, and she is a blessing in any family and to any family physician or any family surgeon. She never weighed more than 110 pounds in her life. She has not been in bed a day since her last child was born thirty-five years ago. She hops, chirrups, cavorts all over the place and has been in at the birth and sickness of all the grandchildren and is still the dynamo; she is rarely still. Every physician has one or more in his practice and would not exchange her as a prospect for three of the flapper age who lead the sheltered life of the poorly reacting, noncooperating, pampered individual. To consign this type of patient to the aged class because of her calendar age is to consign oneself to the dotage in intelligence.

---

* Read before the Section on Orthopedic Surgery at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

In this day of x-rays, failure to make the diagnosis occurs less often, and even without the films every hip injury is recognized as a fracture if there is rigidity in Scarpa's triangle and if there is inability to lift the heel off the bed with the knee straight.

Formerly, some competent surgeons assigned the class C patients to semirecumbency; the limb was kept in position by sandbags, the heart, kidneys and lungs were watched, and the patient was virtually consigned to the inevitable.

In the A group and in some of the B group the plaster-of-paris abduction cast was regarded as the elective treatment, a method so adequately stressed by Royal Whitman and numerous followers. I have long objected to this form of treatment as a routine because the patient was not a good subject for the act of reduction (with or without anesthesia) or for the process of retention. There were many of my patients in whom this plaster-of-paris appliance became not only immobilization but also immolation; others, notably the wren type, who resented it enough to rebel and get a good physician; others, so fat and bulky that the appliance was unbearable supercargo; others who were impeded so much that respiration became embarrassed despite frequent change of position, and others in whom bed sores developed even when expected and guarded against. Finally, it never appealed to me as rational to immobilize this joint fracture wholly when I mobilized every other joint fracture, especially in view of the bad repair reputation of this articulation.

Like every one else, I have had good results and poor results with this plaster-of-paris treatment. The fact is that, despite perfect reduction and perfect retention, this spica treatment is no guaranty of success in and of itself. Recently, in consultation, I saw such a case in a 19 year old student of sturdy physique.

Accordingly, I have abandoned this early immobilization method in nearly all cases and now resort to traction until union is attained, and I then allow the patient to become ambulatory in walking calipers or a plaster spica.

There is nothing new in this procedure, and as long ago as 1872 Maxwell advocated what in effect is the same treatmnt. Ruth says he was taught this method by Maxwell and hence arose what has become known as the Maxwell-Ruth method. Ruth in 1921 presented this procedure before this very section at the Boston session under the title "Fractures of the Femoral Neck and Trochanters: A Rational Treatment." In a well considered article he refers to the procedure as the "anatomic method," stressing such factors as the early reduction attained by flexing the thigh and then maintaining the corrected position by vertical traction along the entire limb, and lateral traction to control the upper fragment. He asserts that union is obtained in about four weeks, and thereafter the patient is ambulatory on crutches or in a brace for a period of from "four to ten months." He says that unaided walking is possible in trochanteric fractures in six months, in eight months in extracapsular fractures, in twelve months in intracapsular fractures.

As stated, the Maxwell-Ruth method is to obtain vertical traction by attaching adhesive plaster along the entire lower limb from the ankle to the midthigh. A part of the technic is to mobilize the knee manually at frequent intervals so that a stiff knee may not compromise an otherwise satisfactory result. I modify this part of the process by placing the adhesive plaster on the thigh only, mobilizing the knee by motion obtained through an attachment on the sole or about the ankle.

In this fracture, as in all others, I have long attempted to classify or type the cases in terms of the displacement or nondisplacement of the fragments. Type 1 in any fracture is that group in which the fragments are separated or overlapped; type 2 is that group in which the fragments are in contact and not overlapped. There is as much difference in the management and potential results between type 1 and type 2 as there is between a simple benign catarrhal appendix and a malign ruptured appendix.

Of 100 consecutive cases of fracture of the femur recently reported[1] from my service, 14 per cent were in the hip, the age range varying between 41 and 92 years.

TRACTION METHOD

1. Both knees are flexed to from 150 to 165 degrees. This is best provided by a bed of the Gatch type, which allows the patient to assume a semiseated position with the knees bent to the desired extent.
2. Moleskin adhesive plaster is applied as high as the groin on the inside and to the crest of the ilium on the outside. This encircles the limb except for a spacing of a few inches on the anterior and posterior surfaces. It is held by spiral strips of zinc oxide adhesive plaster and a gauze or muslin bandage into which adhesive plaster is intertwined to prevent slipping.
3. The two lateral straps of adhesive plaster extend three or more inches below the femoral condyles and a spreader is then attached to them.
4. To the spreader a cord is fastened, and this in turn leads to a pulley at the foot of the bed or to the overbed frame of the Balkan type.
5. The limb is widely abducted and internally rotated manually, or that position is attained by the traction. As a guide, a cross is marked on the middle of the patella and the patient and attendants are cautioned to keep this marker pointing straight upward.
6. A weight of from 15 to 30 pounds is attached to the cords and the foot of the bed is elevated on blocks ten or more inches.
7. Adhesive plaster is applied to the sole and to this is attached a cord to permit knee flexion.
8. Lateral traction, if required, is obtained by adhesive plaster passed around the limb as close to the groin as possible. To prevent cutting into the skin, a strip of felt or padded binder board (Ruth) is placed next to the skin, and over this the encircling adhesive plaster is fastened. A spreader is attached to the adhesive plaster and this in turn leads to a cord and weights hung to an upright at the side of the bed opposite the great trochanter. The fracture side of the bed is elevated also if additional traction is needed. The weight is usually one-third that employed in the vertical traction.

If it is impossible to provide adequate home or hospital care, it may be permissible in the "wren" type of patient to apply the plaster-or-paris sitting-in-a-chair cast. To do this a kitchen chair is used, the back and one leg of which is padded; a hole is cut in the seat and then it also is padded. The patient is thus fastened in plaster to the back, seat and leg of the chair. Hence knee and hip flexion is provided, abduction is adequate, and, if wheels or casters are added, this light weight patient becomes self-ambulatory.

---

[1] Goldblatt, David: Ann. Surg. 91:739 (May) 1930.

At night the patient and the chair are placed in bed and thus, virtually, an inclined plane position is constantly maintained.

DURATION OF TRACTION

Within from forty-eight to seventy-two hours, reduction is usually accomplished as indicated by the position and by roentgenograms.

The weights may be gradually reduced after four weeks and usually are removed for a test after from six to eight weeks.

Weights are discarded if: (*a*) the limb does not rotate; (*b*) pushing up or pulling down on the leg gives identical roentgenograms; (*c*) the weights can be pulled up, or the limb can be lifted off the bed by the patient. A period of one week is now allowed with no support except a long sandbag on the outside of the lower thigh. Thereafter, the patient is fitted with walking calipers and a pelvic band. Soon this is discarded at night and later trial trips for weight bearing are permitted. When there is no prolonged reaction in terms of pain, swelling or local heat, the apparatus is wholly discarded. In others at this stage, a plaster spica may be substituted.

On an average the patient is in bed from ten to twelve weeks and up and about on calipers from six to twelve weeks. Thus the disability period approximates from four to six months.

Naturally a patient of heavy build is less early given freedom than a person of light build, and if the roentgen check-up is unsatisfactory, the weight bearing period is postponed.

From the first, the patient is urged to shrug the kneecap and otherwise contract the quadriceps. When available, massage of the limb is provided, and later certain "setting up" exercises for the extremity are prescribed. In other words, physical therapy is made a coincidental and not a retroactive element in treatment.

RESULTS

Disability and deformity to some extent is the usual outcome. However, there are many instances of fair function in the presence of fibrous union and extensive absorption.

In the group in which disability is extreme, the propriety of open operation will depend on the general physique of the patient.

Reconstructive operations are reserved for that group in which absorption leads to nonunion, or deformity is great enough to prove disabling.

ADVANTAGES AND DISADVANTAGES

1. This fracture is placed in the group in which inspection and mobilization are provided after the manner of other joint fractures. The disadvantage is stated to be that this fracture demands immobilization for success; with this statement I do not agree.

2. The general condition and nursing care of the patients are enhanced by the freedom thus provided. The claimed disadvantage is that too much freedom is thus provided.

3. There is no apparatus to impair the local or general circulation; the patient may assume a semiseated position: decubitus can be avoided. On the contrary, it is asserted that a properly applied abduction casing of plaster of paris provides equal security against identical complications. With that view my experience does not correspond.

4. This method affords ample opportunity for inspection and coincident physical therapy. Per contra, it is urged that inspection and physical therapy are not needed in this type of fracture. From that view I also dissent.

CONCLUSIONS

1. Fracture of the inner part of the femoral neck is potentially a hazard because of the anatomic conditions and the tendency toward spontaneous absorption despite adequate replacement and retention.

2. The age incidence adds to the hazard because patients at 60 years or beyond are usually poor surgical risks for any procedure requiring recumbency.

3. Adhesive plaster traction provides adequate replacement and retention without anesthesia and the burden of absolute immobilization represented by the plaster-of-paris spica.

4. Treatment that permits constant inspection, mobility and freedom from local and general stasis accords with the principles found applicable to articular fractures elsewhere.

5. Operative treatment for early cases is usually unwise because of the anatomic and age factors mentioned.

115 East Sixty-Fourth Street.

ABSTRACT OF DISCUSSION

Dr. Charles L. Scudder, Boston: Fractures of the neck of the femur are always intracapsular. Until Royal Whitman suggested as treatment of a fracture of the neck of the femur reposition of the fracture fragments with firm contact and immobilization, the treatment of this fracture could be described as chaotic. Whitman's method has been employed properly and improperly throughout this country. It has not been used abroad generally. There are almost no end-results adequately observed of the Whitman treatment today. In general, the method has not been attended by ideal results. Good function results in from 55 to 60 per cent of the cases. Because of the uncertainty of securing good results, men all over the world have been using different methods of treatment tentatively. There have been many operative procedures with bone grafts, plates and nails, and the method by traction alone and early mobilization. The facts presented by Phemister and Speed with regard to the changes taking place in the head of the femur and in the fractured neck months and years after the injury must be reckoned with in any study of the efficiency of any method of treatment. An interval of several years (from three to five) must elapse before one can get the real end-result of the treatment of the fracture of the neck of the femur. It is possible that opening up the capsule at the seat of fracture, replacing the fragments, grafting muscle to the neck, and leaving the wound open for granulation tissue to enter from an extracapsular source, to bring blood vessels and granulation tissue there, may be helpful. Clay Ray Murray of New York is at work on this problem, and, I believe, is on the right track. Dr. Moorhead believes in the Maxwell Roth method. If he can succeed in correcting and replacing the fragment as the Whitman position does it, that is one thing; but he has not given the results of that treatment. If he can better it and go above the 40 or 50 per cent, there may be something in it, but I doubt very much if the method advocated by Dr. Moorhead will give such results as are obtained by the Whitman method. Operative procedures are merely incidents in the progress of the treatment of fracture of the neck. Smith-Petersen, in Boston, is conducting an experiment with a group of older people. He inserts a steel nail, specially constructed. The fracture is impacted after the nail is in place. His patients have little or no shock or pain, are gotten up on crutches at an early date and bear weight early.

Dr. Kellogg Speed, Chicago: The fate of Dr. Moorhead's stewed bone appealed to me very much. I found it hard to reconcile the picture of this 70-year-old flapper with the stewed bone. I likewise wondered how this dynamic person would be able to electrify the head of the femur which had undergone aseptic necrosis and some of the late symptoms which are often misinterpreted for nonunion of the fracture of the neck of the femur. Sometimes the neck of the femur unites and yet the head later disintegrates and is in a state of aseptic necrosis. A creeping substitution of bone in the head may follow from circulation arriving by the round ligament and the other sources of blood supply to the head; union then occurs, but when the head dies it breaks down, flattens and secondary symptoms follow. Those phenomena are not real nonunion; they are secondary things dependent on certain disturbances, usually unguarded weight bearing as far as any one knows. Possibly this dynamic flapper may electrify this dead bone and cause it to revive—I don't know; but whether the nonunion is true or whether it is delayed change is something yet to be studied and worked out in a careful analysis of cases followed for one, two or five years with roentgen examination.

Dr. Armitage Whitman, New York: I can do no better than to reiterate the conclusion of Dr. Scudder's discussion, that until something better has been devised, the abduction treatment is the method of preference. There are one or two other points of interest. One is the complete difference of opinion that depends on the tools with which one person or another is familiar. There are two schools of thought—that of one who is an expert with plaster, and that of one who is not. It is on that difference that most of the discussion of treatment of fracture of the neck of the femur rests. Sir Astley Cooper spoke of three fractures which did not unite by bone: fracture of the olecranon, of the patella, and of the neck of the femur. I think it can now be agreed that their union depends simply on their efficient treatment. The position of abduction, hyperextension and slight internal rotation is the only one in which the bones are given the opportunity for repair. Given prolonged and efficient immobilization in that attitude and they will unite, even after almost complete absorption of the neck. Dr. Moorhead spoke of his grandmother, immolated in plaster of paris—a statement correctly reflecting the feeling of the average practitioner and the average nurse. To me, plaster means exactly the reverse. The moment the fracture is reduced and the plaster applied, the patient is relieved of pain. He may be, and must be, turned in bed. He may be set up on the side of the bed. He may be taken home and cared for by absolutely untrained attendants, representing a considerable economic saving. Most important of all, Dr. Moorhead's grandmother would have died not only of pain, bed sores and filth, but chiefly of depression induced by the tradition that fracture of the hip in the aged is a terminal injury. When I have his grandmother in plaster, able to turn without discomfort, to sit up, to go out, even to be sent from San Francisco to New York, the psychologic effect is of incalculable importance. I know of no treatment that is 100 per cent effective, but I must emphasize that in proper hands, given a person who knows how to apply plaster of paris, the abduction treatment with the plaster-of-paris spica is not only the best treatment for the fracture but also the best treatment for the patient.

Dr. John J. Moorhead, New York: Without attempting to show the five or six slides which emphasize what I tried to say, I will say that by a process of traction and suspension an attempt was made to produce the position of abduction and to go through the first phase of treatment of any fracture and reduction and maintain it by a nonimmobilizing form of apparatus and apply some form of ambulatory treatment. I should like to emphasize this: All know the greatest difficulty in getting union in this type of case and the embarrassment felt in having a case presumably going on to a very nice state of repair and suddenly it goes over, and under the best possible statistics. Dr. Scudder says that from 45 to 50 per cent of these patients do get satisfactory results, and it occurred to me if that was the best that could be done by outsiders and my results were no better than that, it might be worth while to treat a series of patients by traction and suspension, which was the method giving such excellent results in other types of fracture, and that was the purpose in calling attention to this.

PLASTIC REPAIR OF INGUINAL HERNIA *

JOSEPH A. PETTIT, M.D.
PORTLAND, ORE.

In the majority of herniorrhaphies, either direct or indirect, the chief complicating factor confronting a firm and secure closure is the necessity of making an adequate provision for the transmission of the structures of the spermatic cord. It is on this account that the closure of an inguinal hernial opening in the female is a simpler and surer procedure.

The Bassini operation, though adequate in a large number of cases, is in reality no more than the removal of the enlargement of a congenital sac and resuture of the structures, plus a floor construction of muscle tissue that is not firm and the conjoined tendon that must be under unsafe tension. It presents the disadvantage of leaving the opening directly through the aponeurosis, which is the fundamental tissue support, ranking next to bone in this respect, thus leaving a postoperative *"weak spot" in a vulnerable portion of the aponeurosis.*

With these points in mind, I worked out a technic years ago employing the principles of plastic surgery which I believe is applicable to the majority of surgical procedures for the repair of inguinal hernias, whether direct or indirect, securing the integrity of the cord in a new formed canal and at the same time enabling as secure a plastic repair of the defect in the male as in the female.

About the time this technic was brought out Skillern presented a plastic flap technic lacking in the essential advantages presented by mine. About five years ago Roberts presented a plastic repair along different lines but having advantages over the old Bassini procedure.

Muscle fibers per se are inadequate to resisting strain. Fascia may be considered as flexible bone, being made *up of similar mesoblastic structure minus the lime salts.* Just as the fascia holds in position the groups of muscles moving the long bones of the body, so does the fascia of the abdominal cavity hold its structures within it. These facts are fundamental and should be borne in mind in the consideration of herniorrhaphy. The successful suture of a postoperative hernia is enhanced by an overlapping or plication of the strong fascia, and the employment of this principle has made the Mayo umbilical hernia technic a standard procedure for years. The same principle applies to the inguinal hernias, and if the principles are correctly carried out the successful result is practically as sure as in the repair of the umbilical hernia.

The weakest point is the lower extremity of the inguinal canal from Hesselbach's triangle down to the pubic spine. To bring the spermatic cord out of the *abdominal cavity at this point interferes with a firm* repair in the most vulnerable area for recurrence. It is on this acount that the technic presented is advantageous. The opening for the cord is removed from the weakest point and at the same time the vulnerable area is covered with a double fascial layer beneath which the conjoined tendon and muscle may also be attached to the contiguous inner aspect of Poupart's ligament for additional reinforcement.

The marginal suture does not insure the security as does the plication of fascia. This is especially true in the lower extremity of the external oblique aponeurosis, which is sometimes attenuated or presents the appearance of thickened bands loosely bound together. While the *marginal suture line may not give way in such a* case, subsequent strain may separate the fascia above or below the suture line. Such a separation already exists at one point in order to permit the exit of the spermatic cord.

---

* Read before the Section on Surgery, General and Abdominal, at the Eighty-First Annual Session of the American Medical Association, Detroit, June 27, 1930.

Plication, as extensive as the local conditions and structures present may permit, enhances the permanence of a closure as no other suture can. It is far superior to depending entirely on suture of deeper and less firm structures of the muscle or depending on the suture of the conjoined tendon to the lower end of Poupart's ligament, which must necessarily be under a more or less hazardous tension. Soft structures such as muscles or firmer structures sutured under tension are not dependable. By removing the cord from this insecure area and plicating the medial flap of the external oblique aponeurosis beneath the lateral flap, a double aponeurotic layer is placed as a covering over this vulnerable spot, and no opening is left at this point. Beneath the flaps of the aponeurosis Poupart's ligament may be sutured to the conjoined tendon and the triangular fascia, down to and on the pubic spine as the size of the flaps warrant, as additional support. The cord is placed as far toward the upper end of the incision in the aponeurosis as the anatomic environments warrant, beginning at the internal ring, and is brought out through a new canal between the two layers of the aponeurosis. The direction of the cord in its new canal is medial and slightly upward. The plication is then continued beyond the new canal externally. This plication is secured with two rows of continuous sutures, with or without a few intermediate sutures. The exact method of placing these sutures should be governed by the anatomic materials available in the immediate case. As the cord emerges from the internal ring, it is not angulated but bends loosely, medially and slightly upward, resting on a soft muscle pad.

Emerging from the upper suture line, which may be termed the new external ring, it loosely takes a downward medial course. I never experience any difficulty on account of the slightly greater cord length required, because a greater length can be readily secured by loosening the surrounding tissues down toward the scrotum. It has been my experience that, if the testicle is temporarily held higher by this procedure, it gradually gravitates to a relatively normal suspension point. The embryologic ability for elongation and descent may not be entirely lost in adults.

Prior to the plication, as just described, of the external oblique aponeurosis, a preliminary deep suture of the conjoined tendon and fascia of the internal oblique may be made to Poupart's ligament, thus adding a third layer of firmness to the new-formed wall. This last reinforcement is the only added support which the Bassini adds to a simple fascia resuture, and there it must even be placed in a less advantageous position than is possible in the technic advocated in this paper.

It is advantageous to make the lower flap of the aponeurosis as long as possible. This is facilitated by a high splitting incision from the external ring. If the splitting is started at the medial aspect of the ring instead of at the highest point, a maximum length may be obtained and when the suture is completed all evidence of the former external ring is entirely effaced.

I find three distinct disadvantages in the Skillern operation, in which the lower or lateral flap is plicated beneath the upper or *medial flap: (1) It is not possible to make so extensive a plication; (2) it is not possible* to construct a new fascial canal for the structures of the cord without producing an additional curve having a sharp and disadvantageous angulation, and (3) the general reconstruction is anatomically incorrect.

The new canal for the cord as constructed in this technic is between the two layers of the aponeurosis at *a right angle to the direction of its fibers; therefore* strain and tension compress the canal and inhibit the possible formation of a new hernial protrusion. Such a compression has never, in my experience, produced any untoward effect on the vascular structures of the cord.

The new internal ring made by suture of the border of the upper flap low down on Poupart's ligaments *beneath the lower flap (following suture of internal muscle and conjoined tendon) is identical with the old* internal ring and the point of beginning of the new fascial canal. This point of angulation is not acute and the cord bends over a soft muscle pad. Furthermore, as the cord emerges from the new external ring, higher and medially, the bend is neither sharp nor disadvantageous.

The *technic as advocated, with the plication of the* lower or lateral flap over the upper or medial, presents advantages: (1) the broadest plication for insurance of permanence of closure; (2) the elimination of any sharp angulation of the cord which might be detrimental to its functional integrity, and (3) a new inguinal canal between fascial layers, which is compressed by strain or tension, thus mitigating the possibility of a recurrence of a *hernia.*

There is a diversity of opinion regarding the type of suture for herniotomies. Many have faith in the security of interrupted sutures individually tied. Here again may be gained a lesson from the general principles of plastic surgery; namely, the fewer buried knots the better, because of (1) the slowness of knot absorption with the possible danger of sloughing out, and (2) the *possible danger of constriction from tight tying.* The running suture, when accurately placed, favors ready absorption and is adequate to hold for the length of time that is required for fascial cohesion. The running stitch is not likely to produce the constriction that a single tie may.

Double chromic catgut of not too heavy a size will endure much longer than necessary for fibrous tissue cohesion, and with its use the number of knots needed is reduced to a *minimum. I apply the running* suture in such a way as not to cross the new fascial canal; thus there is no pressure from the sutures on the structures of the cord. The flaps are sewed separately above and below the canal and all sutures are tied separately on either side of the new canal.

By making a curved skin and fatty layer suture with a convexity upward some little distance above Poupart's ligament and reflecting the skin flap downward, the skin incision can be more securely dressed after operation, thus minimizing danger of subsequent contamination. A deep suture of the superficial fascia and fatty layer eliminates dead spaces and makes a soft cushion over the cord, as it lies on the outer surface of the external oblique aponeurosis.

The fascia, as bone, unites readily if all intervening tissues are removed, permitting actual *contact of like* structures. It is essential to remove *the aveolar tissue* and fat particles thoroughly from the coaptating flap surfaces in order to secure a prompt and firm cohesion.

CONCLUSIONS

1. Better results may be expected if the fine principles of plastic surgery are applied to herniorrhaphies.
2. Fascia is the dependable tissue in a herniorrhaphy. Marginal suturing does not prevent a tendency of attenuated fascia to split. On the other hand, complete plication gives a greater coaptating surface and gives a double fascial covering.
3. The construction of the new canal minimizes, if not nullifies, the possibility of another peritoneal protrusion.
4. The direction of the new canal does not create any sharp angulation of the cord, produces no constriction, and permits the greatest degree of overlapping or plication of the flaps.
5. Careful construction and suturing of the flaps gives a maximum amount of "double layer fascia."
6. A careful cleansing of the coaptated fascial surfaces favors a prompt cohesion and avoids what might be termed a "fascial pseudoarthrosis."
7. Fixed routine should not be carried out in every case. Existing environments and available anatomic material should govern details of technic.
8. I believe that my technic eliminates the postoperative "weak spot" as well as lessening other insecurities of repair by the ordinary technic and makes the male herniorrhaphy practically as sure as in the female and almost as certain as the plicated umbilical.

322 Alder Street.

ABSTRACT OF DISCUSSION

Dr. Henry J. Vanden Berg, Grand Rapids, Mich.: Dr. Pettit's operation is a good one; I have used practically the same method for a number of years. It is particularly useful in the direct hernia. The operation should be as simple as possible. In many cases, removal of the sac, if it is done completely, is all that is necessary. In order to do that, the best way is to close it from within, open the sac so that one can see exactly what one is doing, and put in the suture from the inside where it belongs. All are aware how effective the treatment of a femoral hernia is if it is done from within. In a child, that is sufficient in most cases; it is also in many adults in the simple cases. An important matter in the treatment of hernias is doing it in a painstaking way, doing everything carefully, tying knots securely. Too heavy sutures should not be used; the tissues should not be strangulated. The operation should be a work of art, done well and nicely. It does not matter so much what method is used. The same method cannot be used in every case; one has to use one's judgment about that. But it is important that one does it well. If it is so done, there will be few recurrences. Of course, there always will be recurrences, because tissues are being treated that do not heal well, and other things may happen; but if pains are taken it will help a great deal if there is no infection. Infections cause a certain amount of recurrences. Particular care must be taken with asepsis. Hematomas may produce a recurrence, so pains must be taken with hemostasis, especially with the little veins that are not thought much of; they may bleed later and spoil a good piece of work. Patients should not get up too early. They should be in bed for twelve or fourteen days or longer with old people whose tissues are not well nourished and do not heal readily. Then patients should be advised when they leave the hospital about not getting back to work too soon or putting any undue strain on the parts too early. They should be cautious, for from three to four months at least, and somewhat so for six months. Patients should be cautioned in winter against slipping on the ice or getting a sudden strain.

JUVENILE DEMENTIA PARALYTICA

A STUDY OF FORTY CASES *

WILLIAM C. MENNINGER, M.D.
TOPEKA, KAN.

Any disease of which there have been more than 500 reported cases cannot be regarded as rare, and yet the incidence of juvenile dementia paralytica is probably under 1 per cent of all cases of dementia paralytica and under 2 per cent of all cases of congenital syphilis.

The original description of the condition is credited to Clouston,[1] who in 1877 described a boy of 16 who developed a clinical picture resembling in its essential features the adult form of dementia paralytica. It is now known, however, that this is true only when the disease appears in adolescence, whereas the majority of cases appear much earlier. The cases in the literature, for the most part, have been reported as single case reports or in groups of two or three. The only larger groups are those of Mott[2] (1899), 12 cases; Schlicht[3] (1915), 14 cases; Schmidt-Kraepelin[4] (1920), 40 cases, and Klauder and Solomon[5] (1923), 23 cases. Several writers have collected cases from the literature: Alzheimer[6] (1895), 41 cases; Thiry[7] (1898), 69 cases; Fröhlich[8] (1899), 47 cases; Hirschl[9] (1901), 20 cases; Wollburg[10] (1906), 33 cases; Fairbanks[11] (1908), 38 cases; Dahl[12] (1909), 71 cases, and Huguet[13] (1913), 7 new cases.

The present series includes forty cases, heretofore not reported, most of which have been personally examined by me. I am indebted to Dr. William A. White for the privilege of studying twenty-five of these cases at St. Elizabeth's Hospital, Washington, D. C., to Dr. Floyd Haviland for the study of eleven cases at the Manhattan State Hospital, and to Dr. A. L. Skoog for one case.

SUMMARY OF CASES

Sex.—The series includes fifteen males and twenty-five females, or a ratio of 1 to 1.6. This figure is in about the same proportion as that reported in other series and shows a marked contrast to the incidence of dementia paralytica in the adult, in which the ratio is approximately one female to four males.

Age at Onset.—There are several cases reported in the literature in which the onset is said to have occurred in the third year; this was so in one case in this series. This, however, is generally regarded as exceptional, the usual age of onset being between the tenth and fifteenth years.

---

In the present series, there are seven cases in which the break was so gradual that no definite age of onset can be given and in every instance the child was feebleminded and very questionably ever regarded as "normal." There are an additional five cases that certainly must date from birth. On the other hand, there were six cases in which the children seemed normal and presented their first symptoms of dementia paralytica between 9 and 11 years, and twelve patients developing their symptoms between 13 and 17 years.

There are, then, these two very distinct types of onset: the vague and indefinite development of the disease in a mentally and often physically inferior child which may be apparent at birth or soon afterward; second, a more or less acute break, after some years of normal development of the child. In a later stage of the disease, these two groups are indistinguishable clinically and at any stage they are identical serologically.

In settling this question, the problem is made more difficult because, although inferior from birth, the type of case with vague onset is rarely diagnosed as juvenile dementia paralytica much earlier than the other type of case. This may be due in part to the rather low intelligence of the parents in the economic class from which most of the patients come, and in part to the optimism and disregard for comparisons evidenced by the parents of most hypophrenic children.

It must also be recognized that, even though feebleminded, these children disintegrate psychically to even a vegetative level and may exist at such for long periods. This might theoretically be explained in some instances if it is conceded that the progression of the infection is slow. In such instances the child's mental development is more rapid than the destruction by the infection, so that for a time he develops in spite of the presence of the neurosyphilis. It seems incorrect in such cases and certainly impossible to give any definite age as the age of onset, and more correct to regard the onset as at birth.

Duration.—The duration is variously given as from two to ten years, averaging perhaps four years, and usually regarded as being longer than in the adult form of the disease.

Here, again, the duration depends entirely on what is considered to be the age of onset, and in those cases in which it seems to have been present at birth cases may often be found lasting fifteen and even twenty years after the first symptoms.

In the cases in which development has been normal, several of the present cases have lasted more than ten years. In one case at the Manhattan State Hospital, about which there has never been any doubt as to the diagnosis of dementia paralytica and little doubt as to the hereditary quality, the patient was admitted in 1913 when 17 years of age and is still among those present at the age of 34. One patient in this study died thirteen years after the supposed onset, and two patients died after eleven years.

Family History.—Some of the best evidences for a neurotropic strain of spirochetes can be marshaled from a study of the antecedents of young patients with dementia paralytica. In this series, as in many others, a comparatively large proportion (25 per cent of the cases) of the parents have symptomatic neurosyphilis. Of these forty patients, three of the fathers and six of the mothers had dementia paralytica and in one instance both parents had the disease.

In addition, seventeen other patients had one or both parents who were actively syphilitic, three more who were probably syphilitic, and in three additional cases other siblings had syphilis. In one remarkable case the grandparents are all said to have had syphilis, one grandfather having died of tabes dorsalis, and both parents have syphilis, as does the only other child, a brother who is mentally defective.

Mention should be made that while there is no doubt that most cases of juvenile dementia paralytica are congenital in origin, there is no absolute proof in many cases that a primary infection was not acquired in infancy or early childhood. So far as is known, all the present cases were congenital.

Developmental History.—In twenty-three patients (58.5 per cent) of my group there was a retardation in the mental development. Fourteen of them were feebleminded in a marked degree and an additional nine were retarded. Physically, twelve patients (30 per cent) were retarded in their development. Twenty-five per cent (ten patients) gave a history of having convulsive seizures before a diagnosis of dementia paralytica was made. This, I think, is an important consideration in the study of epilepsy of congenital syphilitic origin. I have recently reported thirty-one cases of so-called idiopathic epilepsy in which there was sufficient evidence to establish a diagnosis of congenital syphilis, in which I associated the convulsive seizures with the syphilis. Thus it is apparent that some cases may have been included that may ultimately become frank cases of juvenile dementia paralytica in which the "epilepsy" was a very early symptom.

TABLE 1.—*Incidence of Neurologic Signs*

	Number of Cases		Number of Cases
Cranial Nerve Lesions			
Optic atrophy	7	Strabismus	5
Pupillary changes:		Nystagmus	4
Argyll Robertson	11*	Facial paresis	2
Fixed	18	Speech defect	29

Normal	2	Ankle clonus present	11
Diminished	2	Romberg present	8
Absent	3		

(* *One case showed an Argyll Robertson pupil* on the left and a fixed pupil on the right.)

Bunker has called attention to the frequency in juvenile dementia paralytica of the Lorrain type of infantilism; i. e., the underdevelopment of stature but the maintenance of the body proportions. Subjects with this disease often seem to have arrested physical development, although I cannot agree that this is characteristic of most cases.

Neurologic Picture.—There are certain points of difference between the juvenile and the adult forms as regards the neurologic picture. These differences are preponderantly the increase in extent and variety of the organic manifestations of destruction in the juvenile cases. Thus they show more cranial nerve involvement; i. e., optic atrophy, oculomotor palsy, facial paralysis, speech impairment and dysphagia. The juvenile cases show more extensive pupillary changes, complete fixation occurring much oftener than Argyll Robertson pupils. They show convulsions much more frequently and the motor symptoms in general appear earlier in the course of the disease. They show focal signs more frequently as evidenced by hemiplegias, jacksonian attacks, and occasionally cerebellar signs.

It is my belief that these organic changes are more frequent and more pronounced than in the adult because the disease process involves an immature rapidly growing tissue during its development and an early stage of development is recognized as being more susceptible to influence, more vulnerable to an infection, and more easily destroyed than an adult tissue.

The incidence of the various neurologic signs are shown in table 1.

Endocrine Symptoms.—Autopsy studies show that in a small number of juvenile patients with dementia paralytica there is an involvement of the thyroid, pituitary, pancreas or suprarenal glands. Clear-cut clinical pictures of dysfunction of any of these glands are rare. One patient in this series had suggestive signs of hypopituitarism and one other of myxedema; neither were especially pronounced.

Table 2.—*Occurrence of Clinical Stigmas*

	Number of Cases		Number of Cases
Hutchinsonian teeth	6	Facial asymmetry	11
Deformed teeth	14	Cutaneous lesions (at birth)	7
High arched palate	9	Choroiditis	2
Prominent frontal bossae	3	Hydrocephalus	1
Saddle nose	4	Microcephalus	1

On the other hand infantilism, both of systemic development and of the genitalia, is not unusual. Nine cases (12.5 per cent) showed a general bodily infantilism. In the reports of 530 cases of juvenile dementia paralytica that I have reviewed in the literature, 96 cases showed hypogenitalism. In 223 cases of juvenile dementia paralytica in girls, 24 presented an infantilism of general bodily development. Twenty-six patients of this number showed amenorrhea, 7 of whom were over 20 years of age, 13 between 17 and 20 years, and 5 aged 16 years. These figures unquestionably represent a smaller percentage of such cases than actually exist, since many reports failed to include any mention of menstrual history. Furthermore, many patients with juvenile dementia paralytica develop the acute picture of their disease and may even run their entire course long before puberty and, consequently, are not of an age to show clear-cut symptoms indicating ovarian involvement.

Clinical Stigmas of Congenital Syphilis.—Clinical stigmas are not of particular importance in this condition except in exceptional doubtful cases. They may or may not be present. Their frequency of occurrence in this series is indicated in table 2.

Laboratory Diagnosis.—The blood Wassermann reaction was positive in thirty-five cases; in one it was negative and in four cases it was not made. The spinal fluid Wassermann reaction was positive in thirty-five cases; in five cases it was not made. Examination of the spinal fluid revealed from no cells to 260 cells, the majority of cases showing a normal count (10 cells or less). The colloidal gold curve in cases in which it was made showed a typical first zone (paretic) curve in nineteen cases and a second (syphilitic) zone curve in three cases.

The uniformity of positive laboratory observations is deserving of comment. At least in this series, the uniformity may be in part explained by the fact that a positive Wassermann reaction was regarded as an essential diagnostic criterion by the men originally seeing most of these cases. (Dementia paralytica for many has come to be largely a matter of laboratory diagnosis.) We [14] have expressed in our study of congenital syphilitic epilepsy the belief that the Wassermann reaction in the individual may be negative and yet the presence of congenital neurosyphilis may be established without a doubt. Likewise we believe there might be sufficient evidence in a case to establish a diagnosis of juvenile dementia paralytica with negative serologic observations.

The discussion of the laboratory observations in juvenile dementia paralytica confronts one with the much discussed "preparetic" stage of the disease, i. e., that stage in which the clinical picture is not paretic but the spinal fluid changes are typically paretic. Certainly such a stage must occur in most, if not every, case of the juvenile as well as of the adult form. The diagnosis of every case in the present study was agreed on by several other neuropsychiatrists in addition to myself, so that this point has no immediate bearing on this study.

It is conservative to continue to term such cases "preparetic." Apparently not enough such individuals have been followed after having been spotted as preparetic to determine their course. And yet for the most part we tenaciously hang to the more or less essential paretic colloidal gold curve in fully developed cases of dementia paralytica and at the same time give it questionable support in those feebleminded but neurologically normal patients. It might be a fair question to ask when to consider a preparetic child as having juvenile dementia paralytica. Must a pupillary sign be waited for, or a change in the reflexes, or what? Certainly one can judge from some of the histories of full-blown cases of juvenile dementia paralytica occurring in feebleminded individuals (such as several of the present series) that such cases must have had a "preparetic" stage if one is to concede the fairly well established fact that the spinal fluid abnormalities precede for a number of years the clinical evidences of neurosyphilis.

Consequently, it seems to me that one begs the point in labeling such cases "preparetic" instead of giving oneself the credit for having diagnosed a case of dementia paralytica in an early stage.

Mental Symptoms.—The mental picture seems easiest to interpret if the problem is again regarded as one of an overwhelming infection on an immature but rapidly developing brain. When the damage is done early in life, the result is feeblemindedness with breaking down of the perceptual, intellectual, emotional and motor machinery. When the damage is done later, the brain has had at least a start in its development, and arrest and regression are found at various levels, depending on the age. The later the damage occurs, the more nearly does the case resemble the picture of adult dementia paralytica. Regardless of the age at the time of the damage, all cases tend to assume a common clinical picture of simple extreme dementia.

---

[14] Menninger, K. A., and Menninger, W. C.: Epilepsy and Congenital Syphilis, presented before the Association for Research in Nervous and Mental Disease, Dec. 27, 1929, to be published.

Perceptually, the patient may show only minor changes except for his confusion. It was present in twenty-five cases (62.5 per cent) and disorientation in some degree in twenty-two cases (55 per cent). On the other hand, the patient may retain his more gross orientation until the disease is far advanced, as shown in six cases (15 per cent) of this series. Auditory hallucinations were present in six cases (15 per cent); one patient heard voices saying that her husband wanted her to die; one often heard God talking to him; one received messages and would shout to unseen persons; one heard voices saying good things about him. Two patients had tactile hallucinations, one of electricity and the other ill defined. Only one had visual hallucinations.

The development of the whole field of intellection depends on the age of the patient at the time the damage to the brain makes itself apparent. Early there are varying grades of feeblemindedness; later in all cases there is a deterioration or retrogression to a dementia. There was a history of regression in every case and an apparent mental deterioration in twenty-five of the forty cases. Regardless of the age of onset or previous mental development, the cases all reach a stage in which the mental picture is similar, and, except historically, *different types cannot be distinguished.*

Delusions are not rare in the juvenile cases. Eleven patients (27.5 per cent) in this series had paranoid ideas such as believing that they were being robbed, bewitched, mutilated or persecuted. Three (7.5 per cent) had grandiose ideas. One of the present patients, aged 20, talked of much money; a girl of 17 thought she had fabulous sums on the basis of which she ordered many expensive clothes; the third, a girl of 24, regarded herself as having much worldly wealth. But it seems reasonable to include other cases of younger individuals in which fighting was the result of pride in his prowess. Riding the subway all night was done in the belief that it was his specially granted privilege. Stealing was carried out without appreciation of the social significance. Much attention has been called to the absence of expansive delusions in the juvenile cases and it has been explained on the basis that "ambition and the sexual instincts do not become habitual passions dominating the will until after puberty." Such an explanation would construe grandiose ideas as concerned only with ambition and sexual instincts. It seems reasonable to expect the degree of grandeur of the ideas to be proportional to the age of the patient and consequently one cannot expect *in the child the ideas of grandeur seen in the adult.*

Emotionally the usual picture is an inadequate flattened response (twenty-four cases) with silliness, childish superficiality and euphoria. Many (twelve patients) are irritable at times and respond to any stimulus with a whine or a cry, or a temper outburst. Depression is occasionally present (eight cases); fourteen cases showed excited periods and six presented alternating periods of laughing and crying spells.

Much of the psychopathologic condition of the patient with juvenile dementia paralytica is demonstrated in his activity. The first mental symptoms are often behavior disorders: stealing, fighting, destruction of clothing or property, truancy, inefficiency, riding the subway all night, and other queer, unexplained acts. Eighteen (45 per cent) cases of this series demonstrated antisocial behavior. Mannerisms of speech and action are usually present: rambling silly speech, incessant chattering, profanity, laughing, mutism, collecting waste paper and other trinkets, and outbursts of temper. *Fourteen patients (35 per cent)* were untidy and four destructive. One was inclined to mutilate himself in various ways. Two were at times cataleptic and twelve (30 per cent) resistive.

Treatment.—Treatment seems to be regarded as universally ineffectual. In this group five patients were inoculated at least once and several twice with malaria without the malarial paroxysms ever developing. In thirteen others the patient had a malarial course. In nine of the thirteen there was no apparent change afterward; in one there was a temporary improvement which in a short time relapsed, and in the other three there seemed to be a fair degree of remission. Other means of treatment have been entirely unfruitful.

Presumably this fact can be explained if the brain is conceived of as having been so rapidly invaded and the damage so extensive that, even though relatively early in the disease, it is beyond the recuperating stage and the strongest therapeutic agents are ineffective.

SUMMARY

In this paper I have summarized in detail the symptoms and signs in juvenile dementia paralytica, stressing particularly the points of difference between it and dementia paralytica.

I take the position that juvenile dementia paralytica is the interaction of an immature, rapidly developing *personality and a slowly progressing infection, with* early distortion and later inhibition of development, and eventually breaking down of the complete biologic unit. Considered in this light, the various clinical pictures of juvenile dementia paralytica are interpreted and the differences between dementia paralytica in the child and in the adult are emphasized.

Special attention is called to the cases developing in feebleminded and often physically inferior children in whom the onset is often so insidious that it may be assumed to date from birth. I take issue with the "preparetic stage" theory, preferring to regard such asymptomatic cases as early dementia paralytica. Special consideration is given to infantilism occurring in *patients with juvenile dementia paralytica including both* the physical and the mental development, with particular emphasis on the mental picture.

3617 West Sixth Avenue.

ABSTRACT OF DISCUSSION

Dr. Hans Reese, Madison, Wis.: Dr. Menninger's paper is a valuable contribution to the subject of juvenile dementia paralytica. There have been many articles on congenital syphilis but there has been no paper published recently which deals *with juvenile dementia paralytica. It is not a new entity at all* because in 1883 Diday of Paris reported the first relationship between dementia paralytica and congenital syphilis. Dr. Mabel G. Masten, who has reported on our experience at the University of Wisconsin, has found that among twenty children there were ten clear-cut cases of juvenile dementia paralytica, five cases of tabes, and three cases of taboparesis. In her group there was mental involvement in 68 per cent. The occurrence of juvenile dementia paralytica is not so rare. Careful examination of patients with congenital syphilis will reveal a mental deficiency similar but less pronounced than the mental status of acquired dementia paralytica. We do not depend on serologic *manifestations* alone but rely mostly on our clinical observations except in infants without neurologic signs. Endocrine or glandular dysfunctions have been present in all of our cases, which we attribute to an involvement of spirochetes of the endocrine system and not to a germ plasm degeneration. This phase was clearly demonstrated by Zabriskie in 1923. As long as the morphology of the spirochetes is not known, one is not allowed to speak of the neurotrophic or dermotrophic strain. Miscarriages, premature births, stillbirths, defective children, healthy children can be explained better by the gradually decreased virulence of the spirochetes. The mental involvement of juvenile dementia paralytica has been so clearly presented by Dr. Menninger that it is not necessary to discuss further "moral insanity." I feel that the outcome in untreated cases is usually simple deterioration, later a muttering, repulsive creature or a pathetic idiot. In regard to treatment I am not so pessimistic as Dr. Menninger. I feel that one should start with tryparsamide and then submit some patients to malarial treatment followed by either tryparsamide or sulpharsphenamine. Calcium should be added to the therapeutic efforts in cases presenting convulsions, which may be due more often to disturbance in the calcium metabolism than to vascular phenomena. Our results with this suggested treatment have proved to be more beneficial than those of previous reports.

Dr. H. W. Woltman, Rochester, Minn.: Dr. Menninger stressed the prominence of meningovascular features in juvenile dementia paralytica. These as well as the diffuse, subcortical, parenchymatous changes, which may include the basal ganglions, and the frequent involvement of the cerebellum, may lead to the production of clinical pictures that are not always easily recognized as juvenile dementia paralytica. Few other diseases exhibit a combination of such extreme physical and mental dilapidation. I must confess that I have lost much of my assurance in making a diagnosis of dementia paralytica, particularly in adults, in the face of negative serologic evidence. As Dr. Menninger said, it can be done and it has been done correctly, but I have been unable to forget a victim of my diagnostic acumen who unobligingly dropped dead with tumor of the brain about three days after I had cast to the winds a negative serologic warning. If anything substantial is to be done in the treatment of juvenile dementia paralytica, the disease must be recognized earlier than is usually the case.

Dr. Paul A. O'Leary, Rochester, Minn.: It is difficult for me to concede that the fact that 25 per cent of the congenital syphilitic children who had neurosyphilis were born of a neurosyphilitic parent is an argument in favor of the neurotropism of *Spirochaeta pallida*.. On the other hand, the 75 per cent who did not show involvement of the nervous system, although born of neurosyphilitic parents, is a more forceful point in favor of the lack of specificity of the organism. My experience with acquired syphilis, and congenital syphilis also, has repeatedly impressed on me that the clinical evidence is heartily against the specificity of *Spirochaeta pallida* and strongly in favor of the conception that the course of the disease is the result of the type of the soil on which the organism grows. I share in the pessimism expressed with regard to the treatment of patients with congenital neurosyphilis, after having employed the majority of specific and nonspecific methods of treatment recommended for this disease. The results are much inferior to those noted in the acquired forms of parenchymatous neurosyphilis. As a syphilologist my interest lies in the prevention of juvenile dementia paralytica by the early recognition of nervous system involvement. Even though the incidence of neurosyphilis is only 10 per cent in congenital syphilis, the routine examination of the spinal fluid in all cases of the retarded type is warranted, because the treatment of asymptomatic neurosyphilis is highly successful. The neurologist seldom sees the syphilologist's success but only his failures in neurosyphilotherapy. The routine examination of the spinal fluids of these children is a paramount feature in their treatment and the guide to the prevention of juvenile dementia paralytica.

Dr. W. C. Menninger, Topeka, Kan.: In my opinion, cases of juvenile dementia paralytica are probably fairly common but they occupy a rather unique place because these patients are usually too young to go to the state hospitals and they are often too psychotic to be accepted in institutions for the feebleminded. So one never knows where to look for them. I don't mean to imply in the paper that I support a neurotrophic strain of spirochetes. I mention it because so many of these cases do show neurosyphilis in the family history.

Clinical Notes, Suggestions and New Instruments

RUBBER FLASK CONNECTORS FOR HYPODERMOCLYSIS, INTRAVENOUS THERAPY AND OTHER USES

F. M. Pottenger, Jr., M.D., Monrovia, Calif.

Hypodermoclysis and intravenous therapy are at present administered by two general methods; namely, by means of the Kelly bottle and by the inverted flask as a reservoir with the necessary connections. Neither method gives complete satisfaction as used at present. Use of the Kelly bottle necessitates the transfer of sterile fluid from one container to another, offering an opportunity for contamination. To set up the inverted flask with the clamp and plate that are universally employed to maintain the stopper in position requires about five minutes. The metal connection corrodes under sterilization and use and the rubber ordinarily used soon deteriorates when subjected to repeated heat sterilizations.

In an effort to overcome these difficulties, two rubber connectors were developed. These connectors slip over the necks of flasks or bottles in the same manner as nursing nipples and are made in sizes to suit the various requirements. By using these, an ordinarily skilful nurse can complete a dozen hypodermoclysis outfits in the length of time required to set up a single plate and clamp.

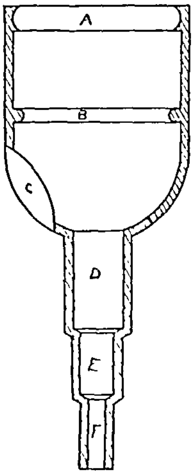

Fig. 1.—Cross-section of single-legged connector with the valve in the side wall: *A*, suction ring; *B*, guard to prevent connector from being pulled down too far; *C*, valve in side wall; *D*, three-eighths inch outlet; *E*, one-fourth inch outlet; *F*, one-eighth inch outlet.

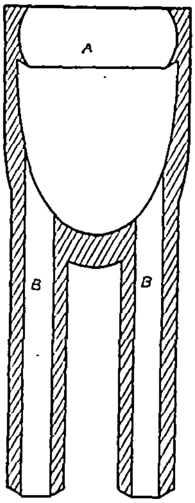

Fig. 2. — Cross-section of two-legged connector. *A*, suction ring; *B*, *B*, outlets.

A high grade, heat-resisting rubber is used in their manufacture. In addition to its chemical resisting qualities, this rubber has withstood without material damage thirty autoclavings at from 20 to 30 pounds pressure. A suction ring cast into the heavy rim provides additional security.

The first device is a single outlet connector with a valve for admitting air, as shown in figure 1.

Intravenous and hypodermoclysis therapy demand an air intake with a fluid outlet from a vessel into a circuit without the loss of fluid through the air inlet. This unit is made of rubber with a suction ring cast near the upper lip to insure a good hold on the neck of the flask or bottle. A second ring cast about an inch below the lip guards the connector from being forced down on the neck of the flask to a point at which the proper operation of the valve would be interfered with.

The outlet is made with three tapers so devised as to make it available for use with one-eighth inch, one-fourth inch and three-eighths inch or larger tubing. If one-eighth inch tubing is used, the connector may be used as it is. If one-fourth inch tubing is used, the one-eighth inch connection is cut off, and for larger sizes both of the two smaller joints are removed.

The valve is placed in the side wall of the connector in such a position that no air bubbles will pass into the outlet tube even though the fluid is allowed to flow freely from the one-eighth inch outlet under a head of 6 feet of water. This is a rate of flow greatly in excess of any used in practice.

An important advantage of this valve lies in the fact that the attending nurse can tell at a glance, by observing the flow of air bubbles through the fluid, whether or not the apparatus is in operation.

The flask, solution and connector may be sterilized as a unit, thus eliminating changes of sterile fluid from one receptacle to another.

TWO-LEGGED CONNECTOR

In addition to the demand for a connector with a single outlet for hypodermoclysis and intravenous uses, there is considerable demand for a two-legged connector both in medicine and in chemistry. Such a connector is shown in figure 2.

This connector possesses the general advantages already described and the additional feature of a double outlet.

The upper portion of the connector contains a heavy suction ring for security under moderate pressures, which makes the connector so firm that the flask or rubber will break before the connector can be pushed off by internal pressure.

In intravenous therapy and hypodermoclysis when objection is raised to the passage of air bubbles through the fluid, the employment of this connector will obviate that objection. A glass tube can be inserted into one leg, or one leg may be manufactured so as to project inward to a point above the surface of the fluid.

This will serve admirably as an inexpensive suction apparatus by connecting a long tube to a floor bottle from one leg and by inserting a glass tube in the other which extends upward above the surface of the fluid.

Numerous other applications become immediately evident to the clinician.

These connectors were first used in the service of chest surgery at the Los Angeles County General Hospital.

URTICARIA AND HAY-FEVER DUE TO TRICHOPHYTIN (EPIDERMOPHYTON INTERDIGITALE)

Fred Wise, M.D., and Marion B. Sulzberger, M.D.
New York

Recently one of us[1] together with Phyllis Kerr reported a case of urticarial hypersensitiveness to trichophytin, in which the passive transference by means of the blood serum (method of Prausnitz-Küstner) proved successful. To our knowledge this was the first case of its kind reported, and we called attention to the fact that the discovery of this type of hypersensitiveness made it possible that trichophytin products of pathogenic fungi might be the cause of some asthmas and hay-fevers, as well as of urticarias. In view of the widespread prevalence of ringworm infections, particularly those of the feet, it would seem to us to be reasonable to consider the possibility of an ever-present allergen in the investigation of patients with these disorders.

Since our first report, Ramirez,[2] in further expansion of our experiments, has discovered and published the report of a case of asthma which could be traced to trichophytin.

The case reported here is the first to have come to our attention in which the products of ringworm fungi (pathogenic hyphomycetes) are shown to have been the causative agents of an attack of hay-fever, and possibly of a typical neurodermite.

It is therefore added to the list of possible allergic manifestations that may be attributed to the presence of ringworm infections; this list already includes eczematous reactions,[3] urticarial reactions[1] and asthma.[2]

REPORT OF CASE

Mrs. W. H. C., a research worker, aged 32, had suffered from skin eruptions since she was a year old. The family history was negative. In childhood the eruption had been of an acute vesicular and weeping character and affected principally the flexures. The dermatitis never disappeared entirely but was subject to improvement and exacerbations. In adult life the skin became more dry and scaly, accompanied by severe itching. Ointments, the roentgen ray and other therapy served only to alleviate the skin symptoms. In addition to the condition of the skin, the patient suffered occasionally from hives and had occasional attacks of asthma and mild hay-fever. None of these conditions were seasonal in occurrence.

Two years prior to our seeing the patient she had undergone a severe tinea of both feet and hands. This was diagnosed and treated by her sister, who is a physician. The treatment resulted in an apparent cure. There are no further historical data that require mention here.

On first examination the patient presented the appearance of a normal woman of her age, with the exception of the skin. A superficial examination revealed no other organic lesions.

Over the entire body the skin was unusually dry, with a slight tendency to scaling. Both cubital regions presented fairly sharply demarcated areas in which the skin was definitely thickened, hyperpigmented and lichenified. At the outer margins of these areas there were irregularly scattered, approximately bean-sized, scratched, lichenoid papules. The sides of the neck were grayish and slightly lichenified, and both they and the face presented a peculiar slaty, or bluish and brownish gray tint, so often observed in diffuse neurodermite. Infiltration and itching were present in all these areas. The scalp was dry and scaly, the face slightly reddened.

The palms and soles were normal in appearance. There were no clinical signs of ringworm of the feet.

The patient and her sister both stated that we were now seeing the skin condition at its best.

A diagnosis of typical generalized and circumscript neurodermite was made.

As it has been a matter of routine, in our office, to test all cases of allergic skin eruptions with trichophytin, and as the patient's history evidenced a previous severe tinea of the feet, an intradermal test with trichophytin was performed. The trichophytin employed was one that we had ourselves prepared from a fungus of the *Epidermophyton interdigitale* group. The manner of preparation followed the standard specifications of Bruno Bloch. While we had already employed this and other trichophytins in a large number (more than 100) different cases, in only one have we seen a reaction in any way, although not entirely, comparable to one which this patient presented.[1]

Immediately after the intradermal injection of 0.1 cm. of trichophytin in the patient's arm, the wheal began to grow. It became white, porcelain-like, presented pseudopods and increased to approximately ten times its original size. An angry red zone appeared around the test site. Within approximately five minutes the patient complained of itching in the nose, and then of generalized itching. Small pea-sized hives appeared scattered over various parts of the body, on the arms and chest. The eyes began to water and attacks of violent sneezing set in. The itching in the nose became worse and there was difficulty in breathing. The eyelids became red and swollen. As the attack had not abated at the end of fifteen minutes, 4 minims of 1 : 1,000 solution of epinephrine hydrochloride was given subcutaneously, and this produced almost immediate relief.

COMMENT

In view of this attack of hay-fever and hives due to trichophytin, the presence of the fungi in mycotic skin diseases must in future be considered as the possible cause of certain hay-fevers and urticarias.

In addition to the typical trichophytids which are known and described, the list of allergic manifestations that can be caused by ringworm fungi or their products can now be enlarged to comprehend eczematous dermatitis, urticaria, asthma and hay-fever.

While the possibility seems to exist that certain cases of neurodermite may have a similar etiology, the evidence here submitted is inconclusive in this particular direction.

200 West Fifty-Ninth Street.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

COD LIVER OIL (See New and Nonofficial Remedies, 1930, p. 255).

The following dosage form has been accepted:

Maltine with Cod Liver Oil and Iron Iodide: Maltine 70 per cent, cod liver oil 30 per cent, and ferrous iodide 0.88 Gm. (2 grains) to each fluid ounce. Maltine is a preparation essentially similar to extract of malt U. S. P., but it contains 3.88 per cent of alcohol and is prepared from malted barley, oats and wheat; as determined by a modification of the method of Chick and Roscoe (*Biochem. J.* **21:** 689, 1927), it contains one unit per gram (28 units per ounce) of vitamin B_1, one unit being the weight of the product necessary as the sole source of B_1 in an otherwise adequate diet to protect growing rats from polyneuritis and to assure normal growth; and ⅓ unit per gram (9 units per ounce) of vitamin B_2, one unit being the weight of the product necessary as the sole source of B_2 in an otherwise adequate diet to protect growing rats from pellagra and to assure normal growth; 1 Gm. converts 5 to 7 Gm. of starch to maltose and dextrin in thirty minutes at from 40 to 42 C. Maltine with cod liver oil and iron iodide contains in 100 cc. from 23,000 to 25,000 fat-soluble vitamin A units as determined by the U. S. Pharmacopeia assay and it has an antirachitic potency such that 0.02 Gm. fed daily to rachitic rats is sufficient to cause perceptible to distinct healing of rickets in from six to ten days as determined by the line test.

Manufactured by the Maltine Company, Brooklyn. No U. S. patent. U. S. trademark 44,566.

DIPHTHERIA TOXOID (See New and Nonofficial Remedies, 1930, p. 364).

Lederle Laboratories, Inc., Pearl River, New York.

Diphtheria Toxoid.—Prepared from diphtheria toxin of which the L+ dose is 0.2 cc. or less. The toxin is treated with formaldehyde at a temperature of 37 to 40 C. until the injection of five human doses into four 300 Gm. guinea-pigs will cause no signs of diphtheria poisoning. It is tested for antigenic power by injecting subcutaneously at least ten guinea-pigs weighing from 270 to 320 Gm. each with the initial human dose; at the end of six weeks each animal is injected subcutaneously with 5 M. L. D. of a stable diphtheria toxin; at least 80 per cent of the animals must survive for ten days. The finished product is adjusted to contain in 2 cc. enough of the toxoid for one immunization treatment. It is marketed in packages of one immunization treatment containing one 1 cc. vial of diluted toxoid for the reaction test and two 1 cc. vials of toxoid for treatment.

COMMITTEE ON FOODS

The following products have been accepted as conforming to the rules of the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

PET UNSWEETENED EVAPORATED MILK

Manufacturer.—Pet Milk Company, St. Louis.

Description.—An unsweetened evaporated milk complying with the U. S. Department of Agriculture definition and standard for evaporated milk.

Manufacture.—Fresh whole milk from healthy cows is obtained a few hours after milking. The sanitary conditions of collection, the handling, cooling and transportation of the milk are under strict supervision. It is tested for cleanness freshness and flavor before acceptance.

The milk is heated in jacketed hot wells to approximate boiling, then conveyed to partial-vacuum pans where from 50 to 60 per cent of the water is removed at from 120 to 130 F. The concentrated milk is homogenized by forcing through small apertures under a pressure of from 2,000 to 2,500 pounds. The fat globules are finely dispersed and later do not readily separate out. It is cooled to from 36 to 40 F., agitated in glass-lined tanks, and tested for fat and total solids. The fat and total solids must be not less than 7.8 and 25.5 per cent, respectively, and the sum of the fat and total solids not less than 33.7 per cent.

The tested milk is canned by injecting through small openings which are automatically sealed. The filled cans are inspected as to net weight, sealing and perfection of can. The sealed cans are processed in retorts at from 240 to 250 F. for twenty minutes, which accomplishes sterilization and favorably affects the viscosity. The cooled cans are stored for several days in a warm room. Any defective or improperly processed cans are discarded.

Composition.—

Total solids	25.5–26.5 per cent
Ash	1.5– 1.6 per cent
Protein (N × 6.38)	7.0– 8.2 per cent
Fat (ether extract)	7.8– 8.2 per cent
Lactose	9.5–10.0 per cent

Calories.—

1.36 per gram.
38.6 per ounce.
618. per pound.

Claims of Manufacturer.—Pet Evaporated Milk is uniform in fat and nonfat content and is sterile. The fat does not separate out. The homogenization makes this milk more readily digestible by babies and children than fresh or pasteurized milk because of softer, more flocculent curds formed in the stomach.

Pet Evaporated Milk may be used for cooking, baking and other purposes as is ordinary milk.

ALACTA

Manufacturer.—Mead Johnson and Company, Evansville, Ind.

Definition.—A dried, partially defatted milk designed for infant feeding formulas in which low fat content is desired.

Manufacture.—The milk is collected from tuberculin-tested cows under carefully supervised conditions. The fresh milk received each day is tested for bacteria, fat, odor, acidity and sediment, and stored in glass-enameled tanks at 50 F. The fat content is adjusted to 1.5 per cent, the modified milk is placed in a closed tank, the air is exhausted to a low pressure and the milk is heated to 230 F. for one and one-half minutes by steam under pressure. This is known as the Grindrod process. The heating occurs in the practical absence of air to minimize oxidation or destruction of the vitamins. The cooled milk is sprayed under high pressure into a current of cleaned, washed, heated air in a drying chamber. The milk solids fall to the bottom as a fine powder. The product is examined by the laboratory to determine whether it fulfils standard requirements and then packed in an atmosphere of nitrogen in hermetically sealed tins.

Composition (proximate analysis).—

	Per Cent
Moisture	1.5
Mineral salts	7.0
Milk-fat	12.0
Protein (N × 6.38)	33.0
Lactose	46.5

Calories.—

4.25 per gram.
121.0 per ounce.
1,936. per pound.

Claims of Manufacturer.—Alacta is a high grade dried milk with part of the milk-fat removed. It is for infant feeding as prescribed by the physician. Alacta contains no pathogenic bacteria. The bacterial counts are normally below 1,000 per gram.

The heating and drying processes effect a physical change which produces fine friable curds from diluted Alacta. The fat is in a finer globular condition than that in fresh or pasteurized milk. The salts apparently are not precipitated. The vitamins A and B (complex) remain practically unchanged, and vitamin C is only slightly affected.

Diluted Alacta may be employed in milk formulas in which a low milk-fat content is desired. Such feedings are sometimes well tolerated when less concentrated but higher fat feedings are not.

The Domain of the Pathologic.—We may say that the organism is healthy when it possesses the capacity to respond adequately to the influences of its surroundings; in a broad sense we may then also say that inadequacy of response indicates departure from health—a pathological state. Maladjustments of every sort will thus fall within the domain of the pathological. —Barker, L. F.: Porter Lectures, University Extension Division, Kansas City, 1930.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

SATURDAY, NOVEMBER 15, 1930

SUPRARENAL FUNCTION

It has been eighty years since Addison[1] announced in London that a peculiar type of anemia associated with severe muscular weakness was related to a marked pathologic condition of the suprarenal glands. In an elaborate review of the accretions of knowledge in the intervening period regarding their possible functions and physiologic significance, Britton[2] of the University of Virginia has made the comment that even in these days of ultraspecialized—it might be called high-powered—physiology, three fourths of a century later, little definite information of suprarenal activity beyond that of the secretion of epinephrine by one part of the gland has been acquired. There have been many disappointments, numerous errors of experiment and interpretation, and several acrimonious debates regarding the claims of discovery, until the casual student began to wonder whether the suprarenals should be put in a category with the spleen or the appendix or the gallbladder as structures of doubtful physiologic potency.

The suprarenals, however, exhibited a feature that early set them apart from the other organs of challenged importance. Suprarenalectomy is a fatal operation. Anorexia and other gastro-intestinal disturbances are early indications of oncoming dissolution; muscular weakness gradually develops and is followed frequently by convulsions, coma and death, usually within one or two days of the obvious appearance of sickness. At first the critics asserted that death following removal of the suprarenals might really be referable to injury of important structures during operation, and to shock and secondary infections. Britton rates it as perhaps one of the most baffling facts to experimental physiologists today that all common laboratory animals from which the suprarenal glands (and cortical accessory tissues when present) have been removed, whether by the single or by the two-stage operation, definitely die within a short period. The complete operation can be conducted with little trauma, in a comparatively short time—from ten to thirty minutes in the case of most animals—and the tissue loss per se is extremely small—roughly, one three thousandth of the body weight. The most skilful surgical technic, combined with optimal postoperative attention, he adds, has not lessened the 100 per cent mortality that follows, usually within a week or ten days, complete removal of the suprarenal tissues.

The discovery of epinephrine in the medullary portion of the suprarenal structures and the demonstration of its unique physiologic potencies aroused expectations of securing a real answer to the problem of suprarenal function. More than thirty-five years ago, Schäfer and Oliver of London observed the marked pressor action of extracts of the glands. The selective action of the potent principle on unstriped muscles and its relationship to the sympathetic nervous system are admitted today. A calorigenic function of epinephrine also is recognized. But the fact remains that ablation of the suprarenal medulla alone is not necessarily fatal and administration of medullary extracts will not avert the impending disaster after complete suprarenalectomy. Thus attention has become focused on the suprarenal cortex. The latest development, notably the work of Swingle and Pfiffner[3] at Princeton University, demonstrates that a cortical extract can be prepared that is able to preserve the life of suprarenalectomized animals apparently indefinitely. The Swingle-Pfiffner extract is being tested with some indications of its efficiency in addisonian cases.

The fact that, in contrast with the rôle of the corticosuprarenal activity, the medullisuprarenal function is not indispensable to life should not be interpreted, as is continually being done, to mean that the medullary hormone is without real physiologic importance. It doubtless renders service in the stress as well as the routine of life. Several reviewers say that without question the medullisuprarenal mechanism along with the sympathetic system, dispensable in the protected conditions of ordinary laboratory life, typifies its great service to the organism at times of critical emergency, when it serves to adjust the pertinent visceral and somatic systems in the body to insure the optimal response to external exigencies. This has often been referred to in The Journal. Britton states in his conclusions that it has been overwhelmingly made clear that medullisuprarenal secretion is intimately and particularly concerned in adjusting and reinforcing bodily mechanisms in times of demand. That the chromaffin tissues can be spared without obviously endangering life yet with some detriment to the organism also appears well proved. Medullisuprarenal insufficiency possibly finds mitigation in the vicarious activity of the sympathetic nervous system. Nevertheless the whole sympathicomedullisuprarenal mechanism may be ablated without fatal result. Addison's disease appears to be more particularly referable to corticosuprarenal deficiency. It has not yet been shown, however, that regressive changes in the medullary tissues do not play a part in the etiology of the disease.

EAT AND GROW FAT

In a recent issue of THE JOURNAL,[1] consideration was given to the failure of many persons, who undoubtedly consume food fuel in excess of their requirements, to deposit fat. According to Wilder[2] of the University of Chicago, obesity may not be just a matter of excessive eating. Some abnormality, possibly an inadequacy of the mechanism of luxus consumption, must be present to account for the inability to rid the body effectively of excesses of food. In any event there, are enough persons in whom the balance between intake and output is favorable to accumulation of reserves to make the question of the management of obesity conspicuous. It might be expected from a biologic point of view that the body should include a protective or regulatory mechanism that would help to avert wide fluctuations in its adult size or weight. The stimulation of metabolism for this purpose, as Wilder intimated, might become an effective agency for averting obesity; it would not be an economic one. Far more probable is the assumption that our instincts so regulate the appetite that it becomes a dependable guide to proper food intake. Harrington[3] has pointed out that under strictly normal conditions the desire for food, that is, appetite, is such that the organism provides itself with materials in amounts that will keep its weight at the ideal level, but often the food intake is either excessive or insufficient to maintain the normal standard.

Everyday life affords examples of the perversion of appetites. Referring to the gastronomic field, Harrington remarked that it has become customary for the normal person to eat three meals a day, and the type of food which he eats is determined by his social and economic status. He gives little thought to the kind of food eaten and often does not remember the menu of the previous meal. However, suppose that a person decides to gain weight and so adds an extra slice of toast and some cereal to his morning meal until he has gained 15 pounds. After he has gained the desired weight, he continues to eat this amount because he has acquired the habit. If he omits these foods, he experiences a feeling of dissatisfaction and has the desire to eat more. It requires a conscious effort on his part to counteract this habit. Appetite and habit must be submerged by a stronger impulse, and the habit of overeating may be as hard to change as the alcoholic habit. Formation of a habit is a simple process, Harrington concludes, but changing the paths of transmission requires a strong impulse and a consciousness involving selection and control, or will.

Physicians frequently encounter situations in which the appetite may be inhibited by phobias to a degree that produces pathologic thinness. On the other hand, Harrington also emphasizes the observation that in obese persons the habit of overeating may be acquired as a means of entertainment, or as an outlet for the emotions. In the latter instance the will to lose weight must be developed before a distorted appetite can be suppressed. In other words, the interest in food expressed by certain types of emotional persons is often so great that some motive must be supplied to make them undertake a change in their food habits.

The clinician called on for corrective advice therefore must not merely consider the caloric aspect of his patient's nutrition but often also the personal peculiarities—the individual psychology—that have led to overeating. As Harrington has expressed it, the normal person may maintain a standard weight over a period of years if his living conditions remain constant and his nervous system remains stable. A decrease in activity, or an increased emotional stress, however, will produce a gain or loss in weight. Emotional stress may cause a loss of appetite, with a consequent loss in weight. The anorexia in the neurologic case can be cured by eliminating the inhibiting force and stimulating other interests strong enough to counteract this desire to avoid food, and the person can be made to gain weight.

In the Department of Internal Medicine at the University of Michigan, Harrington has studied the effects of various types of diet, including the "normal" regimen, a concentrated and a bulky type, on the body weight when the appetite was unrestrained. In the bulky diet the servings of concentrated foods were limited, and the remainder of the diet had to be selected from fruits and vegetables and other foods low in calories. It was adequate in minerals, vitamins and protein, and furnished one calory per gram of weight. In the concentrated diet the amount of low calory foods was limited, and only the usual amount of vegetables as given in the house diet were served. The total bulk of the diet was kept as low as that of the house diet, but the foods offered were highly concentrated. Cream and butter were used instead of milk, and dextrose and sucrose were used for sweetening in order to introduce more calories for a desired sweetness. The diet appeared the same as the normal diet but averaged *2.5 calories per gram of weight.*

All the experimental persons lost weight on the bulky diets. This indicated a loss of body tissue which, however, was not sufficient to force them to take energy enough to maintain their weight when it would have been necessary to eat a mass of food far beyond the habitual volume. Thus the appetite may be thwarted when the customary modes of nutrition are significantly altered without imposed restrictions to eating. Harrington therefore believes that the desire alone for food may not cause the organism to take in as much energy as it uses when the diet is bulky. Appetite may cause an excessive intake of energy when the diet is concentrated. For these reasons, she adds, it is possible to regulate the weight of an individual without any knowledge on his part of the composition of the diet, and, at the same time, completely to satisfy his appetite.

It is important that the medical profession give more serious consideration to the many factors, dietary and psychologic, that the problems of obesity involve. The indifference of many physicians to the details of successful treatment has played into the hands of the quack and the impostor. Thyroid preparations are often used without medical consultation. Parsons[4] has recently pointed out to lay readers that such practice is highly dangerous in the absence of expert medical advice, for thyroxine exerts a stimulating action on the whole of the body metabolism: it does not merely encourage the combustion of fat but facilitates just as much the burning up of more useful and essential materials, such as tissue proteins, so that although an obese person may actually lose weight as a result of taking thyroid extract this loss may be due to removal of essential body constituents as much as to removal of excess fat that the body has stored. And further—seeing that obesity may arise as a result of a number of different causes apart from thyroid deficiency—the person who suffers from it may, and probably will, already possess a normally functioning thyroid, so that when he (or more usually she) takes more thyroid for reducing the fat the harmful effects of excess of thyroxine are liable to be produced. The management of obesity calls for medical intelligence.

THE THEORY OF DIABETES

With the important advances that have been made in recent years in the management of diabetes, during a period that has included the advent of insulin therapy, a growing uncertainty has developed regarding the real nature of the metabolic defects involved. The fundamental observations include the hypoglycemia and loss of sugar through the kidneys. The involvement of the pancreas in the pathogenesis of diabetes is also generally conceded. Beyond that, however, opinions differ greatly.

The majority of those who discuss the perversion of metabolism have concluded that the organism has lost its capacity to oxidize carbohydrates. A recent writer[4] has summarized the current belief by the statement that the loss of sugar is not in itself such a serious matter: it means that so much of the food is wasted, but the body can use other materials besides sugar as fuel in the tissues—fats can be so used, and so can any excess of protein that is eaten over and above the amount that is required for making good the wear and tear of the tissues. But it so happens, he adds, that the burning of fat and the burning of sugar in the body are processes that are not completely independent of each other. If a certain amount of sugar is not being burned in the body, fats cannot be burned completely either.

This is, briefly stated, the crux of the nonoxidation theory of diabetes. The engaging evidence in favor of it is reviewed in every textbook of physiology. There is, however, an alternative theory that has long been championed, especially in Europe. It ascribes the hyperglycemia and glycosuria that occur to an overproduction of dextrose from protein and fat. This overproduction, whose chief site is probably the liver, is great enough to cause the accumulation and excretion of excess sugar, in spite of the continued ability to oxidize it.

The production of sugar from protein in the person with diabetes is generally admitted. The "overproduction" theory of diabetes calls for the conversion of fat into carbohydrate. Striking evidence of such gluconeogenesis from fat has been presented by the Toronto school of physiologists, notably by Chaikoff and Weber.[5] They found that when epinephrine, which "mobilizes" sugar in the organism, is injected repeatedly into depancreatized animals from which insulin and food have been withheld, the excretion of dextrose in the urine may increase far beyond what can be accounted for from preformed carbohydrate, protein and glycerin. This result can be explained only in one way; namely, that the extra dextrose is derived from fatty acid. As to the manner in which epinephrine acts in stimulating the formation of sugar from fat, little that is definite is known; but the available evidence would seem to indicate that it does so indirectly by causing the liver glycogen to disappear.

The overproduction theory assumes at least partially if not wholly unimpaired capacity of the diabetic organism to oxidize carbohydrate. The studies of Soskin[6] at the University of Toronto have made highly questionable the commonly accepted evidence that the diabetic organism suffers complete impairment in its ability to oxidize carbohydrate. The data are technical and need not be reviewed here. However, if the demonstration that totally diabetic animals can oxidize carbohydrate is valid, it upsets the popular theory of the formation of ketone substances in diabetes. As Soskin remarks, it can no longer be assumed that failure of carbohydrate oxidation causes a disturbance in the utilization of fat, whereby the ketone bodies arise. In short, a more exact, if less picturesque, conception should be found than the one commonly quoted as "Fat burns in the fires of carbohydrate." Soskin ventures the belief that, if the ketone substances familiar in diabetes may be regarded as intermediary products in the conversion of fat to carbohydrate, their accumulation in diabetes (like the accumulation of dextrose) is due to the excessive gluconeogenesis that characterizes this condition. Whatever the ultimate answer may be, the "overproduction" theory of diabetes can no longer be calmly disregarded in the interpretation of the complex problems involved. We suspect, however, that it will not long remain free from counterattack.

Current Comment

NATURE OF THE SUBSTANCE IN LIVER ACTIVE IN PERNICIOUS ANEMIA

It is scarcely more than four years since the announcement was made by Minot and Murphy[1] of Harvard University Medical School that, in cases of pernicious anemia, the feeding of liver produces an increased concentration of reticulocytes and mature erythrocytes in peripheral blood. The discovery has been widely heralded and has proved to be alike a boon to the therapeutist and a blessing to mankind. One can readily understand why the search for the "active principle" was prosecuted promptly and vigorously. The ingestion of the requisite large quantities of liver becomes extremely distasteful to most patients. The possibility that the potent substance, or perhaps one of the significant ingredients, might eventually be synthesized in the laboratory as epinephrine has been was an added stimulus to chemical research. Within a short time the evidence pointed against the probability that the active agent is either protein or lipoidal in nature. It was evidently devoid of sulphur or of iron.[2] Then came the isolation of an active crystalline salt by West and Howe,[3] to be followed promptly with the demonstration by Dakin, West and Howe[4] at the Medical Clinic of the Presbyterian Hospital, Columbia University, New York, that a substance clinically potent in pernicious anemia is a compound of beta-hydroxyglutamic acid and hydroxyproline. Both of these substances possess the characters of protein derivatives; the mode of their linkage remains to be ascertained. The unexpectedly simple nature of this highly potent liver substance is indeed surprising. The genius of the investigators in this sequence of contributions deserves a tribute from American medicine.

HYDROPHAGOCYTOSIS

Those privileged to see the Lewis-Gregory[1] motion pictures of fertilized mammalian eggs, mammalian leukocytes and mammalian tissue cultures have seen dramatized many familiar deductions from histology. Two leukocytes racing and struggling for possession of a single food particle, with the cytologic reactions of victory and defeat; cytocannibalism with the elimination of a senile brother; rhythmic cycles of cellular activity and cellular sleep; and the ceremonious ballet of the chromosomes heralding the approach of nuclear division. Accompanying these expected phenomena, however, are numerous surprises, reactions unpostulated by conventional histology. A prominent example is the phenomenon of hydrophagocytosis, in which macrophages mechanically drink the surrounding plasma. The macrophages of the Lewis films are constantly forming and withdrawing winglike or sail-like pseudopodia. Two neighboring pseudopodial sheets meet and fuse at their outer edges, imprisoning a portion of the surrounding plasma. This captured plasma sample is drawn into the body of the macrophage, there fusing with other swallowed droplets to form a unit vacuole. This vacuole does not rupture but gradually loses its water content by protoplasmic absorption or diffusion, the less diffusible colloids remaining behind. The vacuole becomes more and more concentrated as it shrinks in size. Finally there remains but a small granule of semidesiccated colloids. This process can be followed in detail by addition of a nondiffusible dye to the tissue culture fluid. Physiologists will find in the Lewis phenomenon suggestion of a new mechanism of cellular nutrition and mechanical filtration or purification of body fluids. Immunologists will see in it confirmatory evidence of Metchnikoff's belief that the macrophages are the main place of disposal of soluble antigens, and the logical chief site of synthesis of specific antibodies.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10:15 on Tuesday, 10:30 on Thursday, and 10 on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

November 17.	Diabetes: Its Treatment and Prevention.
November 18.	The Early Diagnosis of Cancer.
November 20.	Vincent's Infection (Trench Mouth): Its Control.
November 22.	Philosophy for the Sick.

Five Minute Health Talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

November 17.	Music in Medicine.
November 18.	Music in Medicine.
November 19.	The Sore Throat Danger Signal.
November 20.	Tularemia.
November 21.	Banishing the Blues.
November 22.	Half Alive.

---

[1] The Lewis-Gregory films may be purchased or rented through the Carnegie Institution, Washington, D. C.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Four Health Units to Be Established.—Dr. James N. Baker, Montgomery, state health officer, is reported to have recently announced that health units will soon be operating in Perry, Marion, Henry and Butler counties. With the addition of these units, only eleven counties will remain unorganized in the state. In the organization plan followed, a health unit requires a minimum expenditure by the county of about $3,500 a year, which amount is matched by the state.

CALIFORNIA

Mussel and Clam Quarantine Raised.—The quarantine order issued by the director of the department of public health, July 16, prohibiting the sale of clams and mussels along the coast from Monterey County to Del Norte County, was raised, October 1.

Personal.—At the annual meeting of the Board of Medical Examiners of the State of California, October 20, in Sacramento, Dr. Percy T. Phillips, Santa Cruz, was reelected president; Drs. William R. Molony, Los Angeles, and Charles B. Pinkham, San Francisco, were reelected vice president and secretary, respectively.

Society News.—Dr. Thomas Addis, San Francisco, addressed the Los Angeles County Medical Association, November 6, on "Prognosis in Bright's Disease."——The Los Angeles and San Francisco Orthopedic societies were addressed at a joint meeting, November 8, by Dr. Edward C. Bull, San Francisco, on "Some Observations on Bone Lengthening (Relative to Tibiae and Femora)."

Dr. Pepper Gives Scripps Clinic Lectures.—Dr. Oliver Hazard Perry Pepper, professor of clinical medicine, University of Pennsylvania School of Medicine, Philadelphia, will give the sixth annual Scripps Metabolic Clinic Lectures at La Jolla early in January, under the auspices of the Scripps Lectureship Endowment, to members of the San Diego County Medical Society. The meeting will be primarily in the form of lecture-clinics.

Harvard Fellowships for Medical Students.—The chairman of the Harvard Scholarship Committee of the San Francisco Harvard Club has called attention to the fact that two scholarships of $500 each, available every year for men of the University of California or Stanford University, are open to students of the medical school. Although these scholarships have been established for more than forty years, all the recipients have attended other departments of Harvard than the medical school. The committee will welcome the first application of this scholarship from prospective medical students.

"Dr." C. R. Jackson Arrested.—"Dr." Clyde R. Jackson was recently arrested in San Jose, it is reported, for passing worthless checks. He is reported to be the same individual who, in 1927, visited Ann Arbor, Mich., representing himself as a kidney specialist and stating that he intended to take special work at the university. He cashed worthless checks at two drug stores and left town (The Journal, Oct. 1, 1927, p. 1158; Oct. 8, 1927, p. 1257). According to the chief of police of San Jose, Jackson is wanted by the police in San Francisco, Berkeley, San Diego, Pomona and Compton for issuing fictitious checks.

COLORADO

Licenses Restored.—At a recent meeting of the Colorado State Board of Medical Examiners, the licenses to practice medicine of Drs. Floyd H. Weidlein, Palisade, and Frank F. Stivers, Kansas City, Mo., were restored. Dr. Weidlein's license was revoked in April, 1930, for making false representations in his application for a license to practice medicine in the state. Dr. Stivers' license was revoked in April, 1929, having been convicted of a felony in the district court of Logan County.

Society News.—The Pueblo County Medical Society was addressed, October 21, by Drs. Edward Delehanty on "Importance of the County Society in Organized Medicine" and Constantine F. Kemper, Denver, "Precision in the Treatment of Diseases of the Endocrine Glands"; Mr. Harvey T. Sethman, executive secretary of the state medical society, spoke on "Medical Defense and Liability Insurance."——The Boulder County Medical Society was addressed in October by Dr. Carbon Gillaspie on "Confinements in the Home."——Drs. Lewis H. McKinnie and William P. McCrossin, Jr., Colorado Springs, delivered papers on "Clinical Indications for Thoracoplasty" and "Clinical Indication for Open Operation on Empyema," respectively, before the El Paso County Medical Society, October 8.

Pediatric Department Organized.—At the last meeting of the board of regents of the University of Colorado, a department of pediatrics was organized in the school of medicine. Prior to this time, pediatrics was a division of the department of medicine. Dr. Franklin P. Gengenbach was promoted from the rank of associate professor of pediatrics to professor of pediatrics and head of the department. The following promotions and appointments to the faculty of the school of medicine are announced:

Dr. Alfred Hamlin Washburn, associate professor of pediatrics.
Dr. John William Amesse, assistant professor of pediatrics.
Drs. Roy Parsons Forbes, Emanuel Friedman and Louis Carl Wollenweber, instructors in pediatrics.
Dr. John Bramwell Davis, to associate professor of surgery (urology).
Dr. Henry Williams Wilcox, promoted to associate professor of surgery (orthopedics), and head of the division of orthopedics.
Dr. Charles E. Sevier, appointed professor of surgery (orthopedics).
Drs. Hamilton Ishan Barnard and Atha Thomas, appointed instructors in surgery (orthopedics).
Dr. Lyman Whidbee Mason, appointed instructor in obstetrics and gynecology.
Dr. William Cormack Black, Jr., transferred from the department of clinical pathology to the department of pathology as instructor.

DISTRICT OF COLUMBIA

Full Time Teachers at Georgetown.—The following changes and appointments at Georgetown University School of Medicine have been announced:

Dr. Wallace M. Yater, to whole-time professor of medicine.
Dr. Mario Mollari, to whole-time professor of bacteriology.
Dr. Jacob Markowitz, appointed whole-time professor of physiology.
George A. Bennett, A.B., appointed whole-time professor of histology and embryology.
Theodore Koppanyi, Ph.D., appointed whole-time professor of pharmacology.
Dr. Alexander B. Moore, appointed professor of roentgenology.
Dr. Harry S. Bernton, appointed professor of preventive medicine and hygiene.

ILLINOIS

Society News.—The annual meeting of the Tri-County Medical Society (Warren, Henry, Knox) was addressed at Galesburg, October 13, among others, by Drs. Rollo K. Packard, Chicago, on "Surgical Mortality and Morbidity," and Alexander A. Goldsmith, Chicago, on "Chronic Colitis."——The Quincy Physicians' Club was addressed, November 3, by Dr. Melinda C. K. Germann on "The Progress of Pediatrics"; the club will be addressed, November 17, by Dr. Clarence A. Wells on "Progress of Anesthesia."——Dr. Charles Spencer Williamson, Chicago, discussed "Research Work Along the Lines of Anemia, Especially Nutritional Anemias and Pericarditis" before the Will-Grundy County Medical Society, Joliet, November 5.——Dr. Noble Sproat Heaney, Chicago, spoke on endometriosis before the Peoria City Medical Society, October 21.

Chicago

Dedication of Medical Buildings.—The state department of public welfare and the College of Medicine of the University of Illinois dedicated four buildings, October 29. These buildings, the State Orthopedic Institute, the Institute for Juvenile Research, the Nurses' Home and the Research and Educational Hospital Service Building, are units of the Research and Educational Hospital operated by the University of Illinois. Addresses were given by Governor Emmerson, Harry Woodburn Chase, LL.D., president of the University of Illinois, and Rodney H. Brandon, director of the department of public welfare. After the dedication of these buildings, officials of the University of Illinois laid the cornerstone of their new $1,500,000 Medical and Dental Laboratory Building, at Polk and Lincoln streets. These laboratories are designed to accommodate 200 students in a class. The Research and Educational Hospital has a capacity of 450 beds.

Society News.—At the annual meeting of the Chicago Gynecological Society, October 17, Dr. Henry Schmitz was elected president, and Dr. Julius E. Lackner, secretary.——Dr. Aldred Scott Warthin, Ann Arbor, Mich., will deliver the eleventh annual Pasteur lecture before the Institute of Medicine of Chicago, November 21, on "Problems in Latent Syphilis."——A joint meeting of the Chicago Council of Medical Women and the Chicago Medical Society was addressed, October 29, by Drs. Mabel E. Gardner, Cincinnati, on "Multiple Small Peritoneal Cysts of the Fallopian Tubes," illustrated, and Susan R. Offutt, Rochester, Minn., "Chronic Cervicitis (Office Treatment)."——Drs. Lee W. Dean, St. Louis, and Walter R. Parker, Detroit, addressed a joint dinner meeting of the Chicago Ophthalmological Society and the Chicago Laryngological Society, in honor of the American Academy of Ophthalmology and Otolaryngology and the invited guest, Prof. Emil de Grosz; their subjects were "Relationship of Otolaryngology to Pediatrics" and "Uveitis with Trophic Changes," respectively.——The annual study class of the Chicago Heart Association held its first meeting, November 10; it will continue each succeeding Monday, including December 8; the subjects will include "The Child's Heart," "The Heart Beyond the Midpoint of Life" and "Care and Treatment of Cardiacs."

INDIANA

Society News.—The Fountain-Warren County Medical Society was addressed at Veedersburg, October 2, by Dr. Albert C. Holley, Attica, on "X-Ray Diagnosis of Colonic Flexures with Associate Contraction of Descending Colon and Pains Simulating Appendicitis."——Dr. Ernest Rupel, Indianapolis, addressed the Hendricks County Medical Society at Danville, October 17, on genito-urinary diseases.——"Head Injuries With and Without Skull Fracture" was the subject of Dr. Albert E. Sterne, Indianapolis, before the Wayne-Union County Medical Society at Richmond, October 16.——Dr. Foster J. Hudson, Indianapolis, addressed the Hamilton County Medical Society at Sheridan, October 14, on "Most Common Birth Injuries."——The Carroll County Medical Society was addressed at Camden, October 10, by Mr. Albert Stump, Indianapolis, attorney for the state medical association, on "Cause and Prevention of Malpractice Suits."——Dr. Roscoe H. Beeson, Muncie, addressed the Delaware-Blackford County Medical Society at Muncie, October 21, on state medicine.——The Tri-County Medical Society was addressed at North Vernon, October 15, by Dr. John H. Warvel, Indianapolis, on "Juvenile Diabetes."——The Indianapolis Medical Society was addressed, November 11, by Drs. Cleon A. Nafe on acute appendicitis and Louis H. Segar, "Mastoiditis with Lateral Sinus Thrombosis Without Otorrhea in a Two Months' Old Infant"; the society will conduct a symposium on five years' experience with the malaria treatment of neurosyphilis, November 18; Dr. Ursus V. Portmann, Cleveland, will address the society, November 25, on "Rôle of Radiation Therapy in Treatment of Benign Gynecologic Conditions."——The Muncie Academy of Medicine was addressed, October 14, by Dr. Willis D. Gatch, Indianapolis, on treatment of postoperative surgical emergencies.

MAINE

Society News.—Dr. Bryant E. Moulton, Boston, addressed the Cumberland County Medical Society, October 10, on "Psychiatric Aspect of Delinquency."——Dr. Thomas A. Devan, Rochester, N. Y., recently succeeded Dr. George H. Stone as superintendent of the Eastern Maine General Hospital, Bangor.

Experiment in Graduate Medical Education.—The officials of the Central Maine General Hospital, Lewiston, under the auspices of the Harvard Medical School Courses for Graduates, have announced a plan of graduate medical education for districts removed from large medical centers. The method is to conduct ten teaching clinics either monthly or bimonthly. One thousand dollars has been devoted to put the project into operation and Dr. Soma Weiss, assistant professor of medicine at Harvard Medical School, will head the service.

MASSACHUSETTS

Course in Heart Disease for Practitioners.—The New England Heart Association has planned a series of meetings for New England physicians to present the most approved and up-to-date views concerning heart disease, including various methods of cardiovascular examination. The series began, November 5, on "Auscultation of Heart Sounds." Other subjects to be presented include "Normal Blood Pressure," "Cardiovascular Roentgenology," "Electrocardiography," "Dyspnea," "Blood Flow," "Cardiac Pain" and "Edema." The meetings are scheduled for the afternoon, beginning at 4:30 of the first Wednesday of each month and will be held at the Boston Medical Library (Sprague Hall).

Society News.—The Essex North District Medical Society was addressed at a joint meeting with the Middlesex North and East and Essex South district medical societies, October 22, at the new Veterans' Bureau Hospital at Bedford; the speakers were Drs. Robert B. Greenough, Boston, president, state medical society; Charles E. Mongan, Somerville, "Trends in Medical Economics," and Winthrop Adams, Washington, D. C., "The Veterans' Bureau and the General Practitioner."——"Dermatomes in Man" was the subject of Dr. Otfried Foerster, professor of neurology, University of Breslau, before the Harvard Medical Society, Boston, October 14.——The William Harvey Society of Tufts Medical School, Boston, was addressed, November 14, by Dr. Howard W. Haggard, New Haven, Conn., on "Medicine Through the Ages."——Dr. David Cheever, Boston, lectured, November 12, on the care of the patient, at the Harvard University Medical School; Dr. David Riesman, Philadelphia, will talk on the same subject, November 19; Dr. William H. Robey, Boston, will deliver the George W. Gay lectures on medical ethics, December 3 and 10.——Dr. Harvey Cushing, Boston, addressed the Harvard Medical Society, Boston, October 28, on "Benign Fourth Ventricle Tumors of Childhood: A Review of Seventy-Eight Cases."

MICHIGAN

Personal.—Dr. Asher T. Childers, Cleveland, psychiatrist for Cuyahoga County Juvenile Court for the last two years, has been appointed chief of the psychiatric staff of the Children's Fund of Michigan.——Dr. George W. Westcott, Ypsilanti, and Mrs. Westcott sailed from New York, September 24, it is reported, for Belgian Congo, Africa, as medical missionaries.

Society News.—Dr. Louis H. Newburgh, Ann Arbor, addressed the Wayne County Medical Society, November 4, on "Value of the Insensible Loss of Weight in Clinical Medicine"; the society was addressed, November 11, by Col. Percy M. Ashburn, librarian of the Army Medical Library, War Department, Washington, D. C., on "Contributions to Medical Science Made by the Medical Department of the United States Army."——Dr. Don H. Duffie, Central Lake, addressed the Calhoun County Medical Society, November 4, on "Home Cure of Diabetes."——The second graduate clinical conference on communicable diseases of the Wayne County Medical Society was held, November 5, at the Herman Kiefer Hospital, Detroit. At this session the mechanical respirator originated by Dr. Cecil K. Drinker of Harvard University, Boston, was demonstrated; 214 physicians registered at the opening session, October 29.

MINNESOTA

Medical Journal Celebrates Sixtieth Anniversary.—The *Journal-Lancet* will celebrate its sixtieth anniversary, Jan 1, 1931. In honor of the occasion, it is planned to publish a Sixtieth Anniversary Volume and to send one to every physician and every hospital in the states of Wisconsin, Iowa, Minnesota, North and South Dakota and Montana. Among the subjects to be included in this special volume will be: History of Minnesota State Medical Society; History of the North and South Dakota State Medical Societies; Development of Tuberculosis Work in the Northwest; Development of Preventive Medicine; History of Individual County Medical Societies, and Reminiscences and Reprinted Papers.

Society News.—The Minnesota Academy of Medicine was addressed, November 12, by Drs. Alexander Stewart and William H. Hengstler, St. Paul, on "Observations on Serotherapy in Scarlet Fever" and "Neurologic Aspect of Head Injuries," respectively.——The twelfth annual meeting of the Association of Resident and Ex-Resident Physicians of the Mayo Clinic and Mayo Foundation held at Rochester, October 7-9, was addressed among others by Dr. Robert L. Sanders, Memphis, Tenn., on "The Art of Surgery." Symposiums were held on recent advances in anesthesia, allergic diseases and fractures and clinics were held at the various hospitals. Dr. James I. Scarborough, Little Rock, Ark., was elected president and Dr. Thomas J. Kinsella, Oak Terrace, Minn., secretary.

MISSOURI

Personal.—Dr. Eldon M. Findley, who has practiced in Graham for twelve years, was appointed instructor in physiology at the University of Missouri School of Medicine, September 14.——Dr. William W. Rambo, Jr., St. Louis, was appointed full-time physician and surgeon at the Missouri State Penitentiary, recently, succeeding Dr. Frank W. Gillham, Jefferson City.

University News.—The corner stone of the Edward Mallinckrodt Institute of Radiology of Washington University, St. Louis, was placed, October 2. The building is expected to be completed about January 1 at a cost of $500,000. Within the copper box placed in the corner stone was a picture of the late Edward Mallinckrodt, Sr., who left a bequest of $300,000 for the erection of the institute.

The Woman's Auxiliaries and Hygeia.—The woman's auxiliaries of several county medical societies have recently entered subscriptions to *Hygeia*, the Health Magazine. The auxiliary of the Buchanan County Medical Society entered 116 subscriptions; that of the Gentry County Medical Society, 75 subscriptions; the Lafayette County Medical Society, 83; Vernon-Cedar County Medical Society, 133, and the Jackson County Medical Society auxiliary, 83. Most of these subscriptions are to be sent to school teachers and various associations.

Dr. Abbott Goes to Stanford University.—Dr. LeRoy C. Abbott, St. Louis, chief surgeon at the Shriners' Hospital for Crippled Children, has resigned to accept a position as head of the department of orthopedics in Leland Stanford University School of Medicine, San Francisco. The resignation becomes effective, December 1; Dr. Clarence H. Crego, Jr., first assistant to Dr. Abbott, will be his temporary successor pending the making of a permanent appointment. Dr. Abbott has been chief surgeon at the hospital since it was opened in December, 1923, and since 1925 has been professor of clinical orthopedic surgery at Washington University Medical School, St. Louis.

Plan to Unify Eighty-Five Health Agencies.—Plans for coordinating the eighty-five health agencies in St. Louis under an advisory Health Council were recently presented before the St. Louis Medical Society. The preliminary organization work has been done under the auspices of the Community Council, financed by the Community Fund, but the Health Council is to be a separate group since about half of the health agencies are nonmembers of the fund. The function of the Health Council will be to eliminate the overlapping of health agencies working separately. It is said that the forty-two hospitals, eleven clinics and thirty-two other agencies devoted to the promotion of health in St. Louis and St. Louis County have no relation to one another and therefore spend considerable money and effort ineffectively.

Society News.—The Jasper County Medical Society was addressed, October 14, by Dr. George E. Knappenberger, Kansas City, on "Factors Concerned in the Curability of Peptic Ulcer."——Dr. George Leonard Harrington, Kansas City, addressed the Nodaway County Medical Society, September 12, on "Psychology in Medicine, with Especial Attention to the Neuroses."——"Some Occasional Untoward Effects of Treatment of Syphilis by Arsenic with Special Reference to Skin Exfoliation" was the subject of Dr. Stephen T. Ragan, Moberly, before the Randolph-Monroe County Medical Society recently.——Dr. Charles A. Elliott, Chicago, addressed the Jackson County Medical Society, November 11, on "The Management of Edema"; Mr. Paul Lukenbach of the scientific staff, General Electric Company, spoke on "Newer Developments in Physiotherapy, Diathermy and X-Ray."

NEBRASKA

Society News.—The Fifth District Medical Association was addressed, November 6, at Oakland, among others, by Drs. Clyde A. Roeder, Omaha, "A New Structural Classification of Goiter," and William L. Shearer, Omaha, "Surgery of the Jaws"; after-dinner speakers were Drs. Charles W. M. Poynter, Omaha, "The University Hospital," and Philip H. Bartholomew, Lincoln, "Responsibility of the Medical Profession in the Management of Communicable Diseases."

NEW YORK

Hospital News.—A new $800,000 wing to St. John's Hospital, Yonkers, was recently opened. It has a capacity of 150 beds and doubles the number contained in the old building, which will be reconstructed and made into an administration building.

Another Child Guidance Clinic.—The National Committee for Mental Hygiene opened, September 1, the Child Guidance Clinic of Niagara Falls after two years of preparation, which included definite advances in local social work, recreation, probation service and education. This is the first full-time clinic in a community of between 50,000 and 100,000 people. It is financed for a period of ten years through the Martha H. Beeman Foundation and is headed by Dr. William G. Ferguson. An effort will be made to establish cooperation between the clinic and the University of Buffalo Medical School.

Society News.—The Fifth District Medical Society was addressed at its twenty-fourth annual meeting, in Little Falls, September 30, among others by Dr. John E. Sutton, Jr., New York, on "Treatment of Varicose Veins."——Dr. Charles Gordon Heyd, New York, addressed the Eighth District Medical Society, October 2, in Perrysburg on "Salient Features of Surgical Diagnosis in Conditions of the Abdomen," and Dr. William T. Shanahan, Sonyea, "Epilepsies—Etiology and Diagnosis."——"The County Health Unit and the Need of Hospital Facilities for the County" was the subject of Dr. Thomas Parran, Jr., state health commissioner, before the Greene County Medical Society, October 7, at Cairo.——The Clinton County Medical Society was addressed at Plattsburg, October 14, by Drs. Arthur Krida, New York, and Anton S. Schneider, Plattsburg, on "Surgery of the Knee Joint" and "Phlyctenular Disease in General Practice," respectively.——Clifford W. Beers gave a brief review of his book "A Mind That Found Itself" before the Rockland County Medical Society at Letchworth Village, September 24.——Drs. Edgar A. Vander Veer and Homer L. Nelms, Albany, gave an illustrated lecture on "Nervous Indigestion," October 14, before the Schoharie County Medical Society, and Dr. David W. Beard, Cobleskill, presented a series of three films on "Injuries of the Hand."

New York City

The Second Harvey Lecture.—Karl S. Lashley, Ph.D., Chicago, will deliver the second Harvey Society Lecture at the New York Academy of Medicine, November 20, on "Mass Action and Localization of Functions in the Cerebral Cortex."

Hospital News.—New York Skin and Cancer Hospital has been given a gram of radium in soluble form by an anonymous donor and a special cancer clinic has been opened. With removal of the institution to its future quarters, in the recently purchased Lying-In Hospital, an emanation plant will be installed for which the same donor will make an annual gift of an additional gram of radium for three successive years.

Society News.—The German Medical Association was addressed, November 3, by Drs. Otfried Foerster, Breslau, Germany, on "Palliative Operations of Nervous Diseases," and Charles A. Elsberg, "Modern Brain and Spinal Surgery."——The clinical aspects and management of cardiac neuroses was discussed by Drs. H. Mond and Lewis A. Conner, respectively, before the November 5 meeting of the Harlem Medical Association.——The program for December of the fifth series of Friday afternoon lectures at the New York Academy of Medicine on subjects of special interest to the practitioner will be as follows: Dr. Nellis B. Foster, "The Thyroid"; Dr. Alfred F. Hess, "Therapeutics of Ultraviolet Light," and Miss Frances Perkins, state industrial commissioner, Albany, "Occupational and Industrial Diseases."——Dr. Angelo L. Soresi addressed the Bronx County Medical Society, November 5, on "New Views on Pathogenesis, Diagnosis and Treatment of Ulcer and Cancer of the Stomach, Cholelithiasis and Diseases of the Digestive Organs in General."——The New York City Physicians' Golfing Association held the last tournament of the season at the Oakland Golf Club, October 23. Dr. Harry M. Imboden won the first prize.

First Health Center Opened.—The first of sixteen health centers to be established by the department of health was recently opened in Harlem. At present the center offers prenatal, preschool and dental clinics and a baby health station. Other services soon to be operated will include medical guidance, a tuberculosis diagnostic clinic with roentgen laboratory, and general laboratory facilities for private physicians of the neighborhood. A service will be offered for the examination of tuberculosis contracts, and a venereal clinic will also be maintained. The center houses also the Harlem Tuberculosis and Health Committee, the district offices of the bureau of nursing, the Henry Street Visiting Nurse Association and the Speedwell Society. The health department schedule calls for four neighborhood health centers to be opened each year in districts that show the greatest need for intensive public health work. For the establishment of the first four units of the sixteen health centers to be built within the next four years, the city has allotted $1,000,000. Each unit is to cost $250,000 and one of these will be built each year until every health district in the city, arbitrarily divided into blocks of from 50,000 to 100,000, will have a complete health service available not only to the public but to physicians as well. By this unit decentralization of public health service, each section of the city will have the full services of the health department as well as those of various private medicosociological and welfare bodies.

OHIO

Conference of Health Officers.—The eleventh annual conference of health commissioners with the Ohio Department of Health will be held at the Neil House, Columbus, November 18-21. During the same week a maternity institute will be held for public health nurses, and on the 20th and 21st the Ohio Society of Sanitarians will meet. Among the speakers at the conference of health commissioners will be a discussion of Ohio's recent survey of tourists' lodging houses by

Dr. Walter J. Smith, medical inspector of the state health department, and Charles S. Slade, sanitary engineer, state health department; heart disease and its control measures by Dr. Irl C. Riggin, New York, formerly health commissioner of Lorain County. Dr. Harvey J. Powell, Bowling Green, will outline "Medical Science as the Greatest Factor in Civilization," and undulant fever will be discussed by Dr. Walter M. Simpson, Dayton. There are 162 health commissioners in Ohio representing 178 organized districts. The maternity institute will feature a discussion of the maternity situation, prenatal care, a review of delivery and postpartum care and a discussion of mothers' classes, with demonstrations and exhibits.

Status of Poliomyelitis.—The *Ohio Health News*, October 1, states that the incidence of poliomyelitis was at that time increasing so rapidly that the state department of health sent out an admonitory bulletin to all health commissioners urging them and the medical profession to exercise the utmost vigilance in the detection of cases and precaution to prevent the spread of the disease. The poliomyelitis outbreak began its upward trend in July with thirty-seven cases. In August there were 100 reported cases, which followed a diagonal line across the state from Cincinnati to Cleveland. In September, 305 cases were reported and the October 15 *Ohio Health News* reported only 141 cases for October, which totals 583 cases thus far this year. The bulletin emphasizes a more general distribution of the disease in rural than in urban territory. It points out that contact with either case or carrier was the only method of spreading found in the investigation of more than 1,000 cases in 1927 and emphasizes the fact that definitely paralyzed patients are not the most dangerous to the community, because, being easily recognized, they are usually promptly quarantined and properly cared for.

Society News.—Dr. George E. Rockwell, Cincinnati, addressed the Clermont County Medical Society, October 15, at Marathon, on "Allergy and Its Significance to the General Practitioner."——The Butler County Medical Society was addressed, October 8, at Middletown by Drs. Mabel E. Gardner and Harold F. Downing, Cincinnati, on "Pubiotomy" and "Early Symptoms and Diagnosis of Acute Infantile Paralysis," respectively.——A joint meeting of the Toledo Academy of Medicine and the Clinical Orthopedic Society was addressed, October 31, by Dr. George W. Hawley, Bridgeport, Conn., on "Newer Apparatus in the Treatment of Fractures of the Femur."——Dr. Charles W. Stone, Cleveland, addressed the Mahoning County Medical Society, September 30, at Youngstown, on "Mental Disturbances Seen in General Practice."——Among others, Dr. Loyal E. Leavenworth, Canton, addressed the Stark County Medical Society on "Sterility and Its Treatment."——The twenty-fourth Hanna Lecture of Western Reserve University, Cleveland, was delivered at the Institute of Pathology, October 31, by Prof. M. Weinberg of the Pasteur Institute, Paris, on "Rôle Played by the Anaerobes in the Etiology, Pathogenesis and Evolution of Infectious Diseases."——The Summit County Medical Society, Akron, was addressed, November 4, by Dr. Albert Kuntz, St. Louis, on "Anatomical Basis of Sympathectomy."——Dr. Jacob P. Greenhill, Chicago, addressed the Columbus Academy of Medicine, October 13, on "Forceps Deliveries."

PENNSYLVANIA

Society News.—The Bucks County Medical Society was addressed, November 12, at Doylestown, by Dr. William Bates, Philadelphia, on "Diagnosis of Diseases of the Colon."——Dr. William Wayne Babcock, Philadelphia, delivered an address on "The Romance of Anesthesia" before the Northumberland County Medical Society, November 5, at Shamokin.——The Medical Forum will have as its guest speaker Dr. Isidore W. Held, New York, November 15; his subject will be "Modern Aspects of Jaundice and Its Application to Diagnosis."

Philadelphia

The Mutter Lecture.—It has been announced that the annual Mutter lecture for 1930 of the College of Physicians of Philadelphia will be delivered in Mitchell Hall, College of Physicians, by Dr. Frank H. Lahey, Boston, December 3, on "Management of Goiter and Hyperthyroidism."

Personal.—Dr. Harold F. Robertson has been appointed associate professor of medicine at Temple University School of Medicine. Dr. Robertson, who is a graduate of the University of Pennsylvania, is medical consultant for Dr. Chevalier Jackson and is connected with several local hospitals.

Court Rules Naturopaths Cannot Confer Degrees.—The Pennsylvania Society of Naturopaths, Philadelphia, was excluded from the privilege and right to confer degrees in an opinion recently handed down in Dauphin County Court. The decree forbid the society and its naturopathic college from granting degrees of doctor of naturopathy, doctor of natural philosophy or the honorary degree of doctor of natural philosophy.

Hospital News.—An artificial respirator will be installed in each of the following ten hospitals: Philadelphia General, Jefferson, St. Agnes', University, Episcopal and Germantown hospitals, all of Philadelphia; Chester Hospital, Chester; Montgomery, Norristown; Abington (Pa.) Hospital and Bryn Mawr (Pa.) Hospital. The respirators were obtained through the cooperation of the Philadelphia Electric Company and the United Gas Improvement Company.

County Society and Graduate Teaching.—Two foundations have been established under the control of the Philadelphia County Medical Society to give impetus to graduate teaching. The Dr. Mary Fisher Foundation, established in 1928, held its first annual ophthalmologic lecture, November 12. The Da Costa Foundation plans its first meeting for the season of 1930-1931. Dr. William W. Keen added $500 to the fund recently.

University News.—A series of postgraduate lectures was given by the University of Pennsylvania Graduate School of Medicine: the speaker, October 27, was Dr. John A. Kolmer on "Pathogenesis of Infection or the Agencies by Which Parasites Produce Disease"; October 27, Dr. George E. Pfahler, "General Principles of X-Ray Therapy"; October 31, Dr. Edward Lodholz, "Physiological Basis of Personality," and October 31, Dr. Kolmer, "The Nature and Pathogenesis of Bacterial Toxins."

Society News.—The Philadelphia County Medical Society was addressed, November 12, by Drs. Charles R. Heed on "The Conservation of Vision from an Industrial Standpoint"; J. Milton Griscom, "The Eyes of Your Children," and William Zentmayer, "Importance of Ocular Examinations After the Fourth Decade of Life."——Among others, Dr. F. G. Harrison addressed the Philadelphia Urological Society, October 27, on "Philadelphia's Contribution to Urology."——The Medico-Legal Society of Philadelphia was addressed, October 28, by Dr. Alfred Gordon on "Morbid Impulse, Criminal Act and Mental Responsibility."——Drs. Isaac Andrussier and Charles Mazer addressed the Obstetrical Society of Philadelphia, November 6, on "Incidence, Diagnosis and Treatment of Functional Sterility"; Joseph V. Klauder and Herman Brown, "Study of the Calcium-Phosphorus Ratio in the Serum of Syphilitic Pregnant Women," and Thaddeus L. Montgomery, "The Etiology and the Significance of Necrosis (Infarction) of the Placenta: A Biologic and Histologic Study."

RHODE ISLAND

Society News.—The Providence Medical Association was addressed, November 3, by Drs. Raymond F. Hacking on "Perimetry and Its Relation to Some Intracranial Lesions," and Harry C. Messinger, "The Pituitary and Some Features of Tumors in the Pituitary Region." The association was addressed, October 6, by Drs. Emanuel W. Benjamin and William Louis Chapman .on "Intravenous Urography" and "The Decadent Anatomy of the Colon," respectively.

SOUTH DAKOTA

Society News.—North and South Dakota will hold a joint annual session at Aberdeen, S. D., June 2-4, 1931. This will be a celebration of the fiftieth annual session of organized medicine in the territory of Dakota from which the two states were organized.

VIRGINIA

State Medical Election.—At the annual meeting of the Medical Society of Virginia, October 22, Dr. James Allison Hodges, Richmond, was installed as president; Dr. Isaac C. Harrison, Danville, was made president-elect, and Miss Agnes V. Edwards, Richmond, was reelected secretary. The next annual session will be held at Roanoke.

WISCONSIN

Society News.—The University of Wisconsin Medical Society was addressed, November 14, by Dr. M. Weinberg of the Pasteur Institute, Paris, France, on "Serum Therapy in Diseases Due to Pathogenic Anaerobes."——The Medical Society of Milwaukee County was addressed, November 14, by Drs. Eleanore Cushing-Lippitt and Charles L. Scudder, Boston, on "The Health of Working Children" and "The Indications for the Treatment of Fractures by Operation," respectively. Dr. Scudder conducted a clinic at the new county hospital.

CANADA

Grenfell Hospital in Labrador Burns.—A recent newspaper dispatch stated that the Grenfell Hospital at Battle Harbor, Newfoundland, was destroyed by fire, November 3. It was built in 1892 and had a capacity of thirty beds. This was the first one built in Labrador by Sir Wilfred Grenfell and the principal unit in a chain of institutions 150 miles apart. The hospital was unoccupied at the time of burning, as the mission had moved during October into winter quarters farther inland.

GENERAL

Study of Former Yellow Fever Patients.—The International Health Board is endeavoring through the state boards of health to get in touch with persons who had yellow fever forty or more years ago. It wishes to secure blood to use in investigations to prove whether immunity from yellow fever was permanently established in those suffering from it.

Did You Return the Card?—For months a large force of clerks have been revising and bringing up to date data preparatory to publishing the new Twelfth Edition of the American Medical Directory. Every physician who has failed to return his card requesting directory information is urged to do so at once regardless of whether or not a change has occurred in the information requested.

Birth Rate Lowest in Fifteen Years.—The census bureau recently reported that the American birth rate for 1929, 18.9 per hundred thousand of population, was the lowest since 1915, when such statistics were first compiled on a national scale. The infant mortality rate also dropped to the lowest point on record, sixty-eight deaths of infants under 1 year of age for each 1,000 born. In 1916 and 1918 the records showed that the mortality rate was 101 per thousand deaths.

American Board of Otolaryngology.—An examination was held by the American Board of Otolaryngology, October 27, during the session of the American Academy of Ophthalmology and Otolaryngology. One hundred and eleven candidates were examined, of which eighteen were either conditioned or failed. The board will hold an examination in Los Angeles in the spring, preceding the meeting of the Pacific Coast Oto-Ophthalmological Society, and in Philadelphia at the time of the meeting of the American Medical Association in June. An examination will also be given in the fall, at Indianapolis, preceding the meeting of the American Academy of Ophthalmology and Otolaryngology at French Lick Springs. Prospective applicants for a certificate should address the secretary, Dr. William P. Wherry, 1500 Medical Arts Building, Omaha, for proper application blanks.

Ban on Importation of Parrots Lifted.—The ban on the importation of parrots into the United States, which became effective last January during the psittacosis outbreak was lifted by the U. S. Public Health Service, October 30. Parrots may now be brought in through ports where quarantine officers are stationed, subject to certain regulations of shipping, detention and inspection. Shipments are limited to 100 birds each. No more than ten birds may be shipped in a crate of specified size and constructed with special provision for ventilation and cleansing. All parrot shipments will be detained for fifteen days so that their health may be observed by the quarantine inspector. An individual returning from the tropics or elsewhere abroad may bring in as many as five privately owned parrots without having them held for the fifteen day inspection period. However, these birds must have been kept in a good sanitary environment away from contact with other parrots for at least sixty days preceding entry to this country.

Society News.—At the thirty-fifth annual meeting of the American Academy of Ophthalmology and Otolaryngology, Chicago, October 27-31, Dr. John F. Barnhill, Indianapolis, was installed as president; Dr. Samuel Hanford McKee, Montreal, Que., was made president-elect, and Dr. William P. Wherry, Omaha, executive secretary, reelected. The next annual meeting of the academy will be held in French Lick, Ind., in 1931. Prof. Emile de Grosz, Budapest, Hungary, was elected an honorary member of the academy.——The National Society for the Prevention of Blindness will hold its annual conference in New York City with headquarters in the Russell Sage Building, 130 East Twenty-Second Street, November 17-18, in cooperation with the National Organization for Public Health Nursing, New York State Department of Education, New York City Department of Health and Sight-Saving Class Supervisors and Teachers. Included in the program will be conferences on the relation of lighting to vision conservation and medical social service in conservation of vision; conservation of vision in school children and sight-saving class activities in America. Dr. George S. Derby, Boston, will address the meeting on "Conservation of Eyesight with Especial Reference to Glaucoma."

White House Conference on Child Health.—The White House Conference on Child Health and Protection will be held in Washington, D. C., November 19-22, to consider studies made by its staff of more than 1,200 experts during the last year. President Hoover will address the conference at its opening session and his message will be broadcast over a national hookup to previously arranged groups of interested men and women throughout the country. Reports of the technical work of the committee will be divided into four major sections in charge of Dr. Samuel McC. Hamill, medical service; Surg. Gen. Hugh S. Cumming, public health service and administration; F. J. Kelly, Ph.D., education and training, and C. C. Carstens, Ph.D., the handicapped; prevention, maintenance, protection. Arrangements have been made for the various committees to perfect their reports at breakfast and luncheons. The conference is made up of delegates invited by the President, appointees of the governors of the several states and selections made by committee chairmen. The general session will be addressed, November 20, by Hon. James J. Davis on "The National Economy of Child Health and Protection," and the public meeting, Friday evening with radio broadcast, by Dr. Ray Lyman Wilbur, "A Survey and a Challenge"; at 12:45 p. m. Saturday, he will summarize the conclusions and recommendations of the conference in an address which will be broadcast over the National Farm and Home Hour hookup. The White House Conference on Child Health and Protection was called by President Hoover as an extragovernmental function. In addition to the integration of existing information, the committee has carried out several interesting pieces of original investigation, among which is the family interview survey conducted by the Committee on Medical Care for Children with the cooperation of the department of agriculture. The general committee's work has been financed by special grants from private sources supplemented by special grants from foundations and associations having a particular interest in the conference studies.

FOREIGN

Indian Government Accepts Rockefeller Gift.—The government of India has accepted the offer of the Rockefeller Foundation to build and equip an All-India Institute of Hygiene in Calcutta. Lieut. Col. A. D. Stewart has been appointed director-designate, a site is being acquired and all provisional plans have been made. The institute will afford opportunity for research and teaching in problems of public health with special reference to Indian conditions and will cooperate with the present Calcutta School of Tropical Medicine and the affiliated Pasteur Institute, the Carmichael Hospital for Tropical Diseases and the Leonard Rogers Laboratories. The latter has a special staff working on leprosy, kala-azar, hookworm, intestinal diseases and filariasis. The Calcutta school published more than eighty technical papers on tropical problems last year.

Health of Aviators.—The figures relating to sickness and death in the Royal Air Force during 1929 were slightly higher than during 1928. The annual report states that 83.3 per cent of the total sickness was associated with disease, and 16.7 per cent with injury. The increase in the disease rate was due to increase in influenza and tonsillitis at home and malaria abroad. The rate of venereal disease, 15 per thousand, is the lowest yet recorded. A slight increase in the invalid rate was due to cases of the enteric group sent back from Iraq. An increase in invalid cases was noted for tuberculosis, valvular heart disease, chronic suppurative otitis media and mental diseases, and a decrease was noted on account of the psychoneuroses, defective vision and fractures. During the year seventy-two deaths from injury compared with ninety-seven deaths in 1928 were noted, and there were thirty-three deaths from disease compared to forty in 1928. The investigations of effects of fast flying and intensive aerobatics showed that no special physical examination was necessary and that the rotation test to ascertain suitability of the applicant was as precise as the specially designed whirling arm used in the Central Medical Establishment. The dimming or "blacking out" of the aviator's eyes occurring when steeply banking at high speed and reported to be due to a withdrawal of blood from the eye itself does not incapacitate the individual from managing aircraft but should be taken by pilots as a warning not to increase these effects by turning farther.

Existing correction prod.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct. 25, 1930.

The Distribution of Population

At the centenary of the Royal Geographical Society, now being celebrated in London, Mr. A. M. Carr-Saunders, professor of social science at Liverpool University, discussed several aspects of the distribution of population. He pointed out that in certain regions, such as the East Indies, the population was sparse, though the natural resources were considerable, because the skill of the inhabitants was low. With increased skill a much larger population could be accommodated. In the so-called new countries, where the aboriginal populations had been pushed aside, there were also possibilities of absorbing surplus population. In Europe almost alone was there pressure of such a nature as to make likely outward movements supported by force, if it was not otherwise eased. Sufficient notice had not been taken of the declining birth rate of Europe. In all the countries of northern and western Europe the situation was such that if the fertility and mortality rates now prevailing were stabilized at their present levels, the population would before many years begin to decline. There was no longer a replacement birth rate, and, while mortality rates rapidly decreased, the birth rate continued to fall. In southern and eastern Europe the position had not been examined with the same care, but the tendencies were in the same direction, except in Russia and one or two small Baltic states. Outside these areas the problem of disposing of the surplus and relieving pressure in Europe was therefore limited in amount and in time. The new countries were experiencing a similar fall in birth rate. The United States had now only a replacement birth rate. It seemed that the new countries were not going to fill up by the natural increase of their inhabitants and that they could take immigrants from Europe to an extent that would go far to relieve such pressure as existed, though it was by no means certain that they would be willing. Hence the importance of the immigration laws at the present time, since they might block the most promising outlets for the relief of pressure. If international understandings could be reached on migration the future of the white races was bright, so far as that was concerned. The same could not be said of the non-European races that were not controlling their birth rates. These had serious overpopulation in large areas, but that did not constitute a world danger because the pressure led not to movements with force behind them but to internal weakness. The effect was disastrous to those who suffered from it, but it affected the rest of the world only indirectly.

London's Lowest Birth Rate

The lowest birth rate ever recorded in London is announced by the health officer, Dr. F. N. Kay Menzies, for the year 1929. Births in that year numbered 70,089, or 15.8 per thousand of population, against 16.2 in 1928. The number was actually fewer by 887 than in 1918, when the influence of the Great War was at its height. It is estimated that the population of the official "County of London" has decreased from 5,524,000 at the time of the last census in 1921, by 94,000, to 4,430,000 in the middle of 1929. Deaths in the civil population during the year under review numbered 62,889, or 14.2 per thousand, against 12.1 of the previous year. This increase was due to the influenza epidemic, associated with an unusually rigorous winter, and in addition to the prevalence of whooping cough. Fatal street accidents increased from 747 in 1928 to 814. The report states that there are about 30,000 basement dwellings in London, housing about 100,000 persons, which are not fit for human habitation. It will be noted that the fall in the population of the "County of London," amounting to 2,263, is not due to excess of deaths over births. It is largely due to migration to the outlying parts of "greater London," which still continues to grow.

The Sterilization of Mental Defectives

The sterilization of mental defectives has been a topic of controversy for some time in this country. In a letter to the *Lancet,* Drs. Langdon-Down, J. A. Ryle and C. P. Blacker advocate a special form of sterilization—before marriage. The board of control of lunacy administration, in its report for 1929, recommended prohibition of the marriage of mental defectives. But these physicians think that the end in view—the prevention of procreation—could be realized more effectively, more humanely and less dangerously by making marriage conditioned on previous sterilization. They point out that certain high grade defectives are highly fertile and have many illegitimate children. If they are legally prohibited from marrying, promiscuity would be promoted. Many of them also have strong sexual needs and it is hardly humane to deprive them of lawful marriage. Finally, the promiscuity due to preventing marriage would promote the spread of venereal disease.

A National Maternity Service Foreshadowed

Addressing the annual conference of the labor party, Mr. Greenwood, minister of health, said that it was a tragic thing that maternity was the deadliest of callings, that every year 3,000 mothers should die in the performance of the greatest of all tasks and responsibilities. Yet 60 per cent of maternal deaths were preventable. Moreover, the conditions that led to the deaths of the 3,000 might leave their mark for life on many of the 700,000 who survived. The problem was a baffling one, and so far from the maternity death rate declining, it had actually been increasing. The situation was due to many causes. He was going to say to the local authorities: "Parliament has placed in your hands, in the public health responsibilities which you bear, opportunities for dealing with the problem." He hoped that local authorities would make the necessary provision for antenatal treatment, for maternity hospitals and for postnatal treatment. But it was necessary to go further and to evolve a national maternity service, and the government would do that as soon as possible. To deal with the problem effectively, every form of health provision and health service must be mobilized. Local authorities and the medical profession must be consulted with a view to framing a comprehensive scheme.

The British Red Cross Society

The British Red Cross Society has published a volume containing a report of the first conference of the Empire Red Cross Society, held in London last year. The book shows the widespread activities of the society. In Canada, for example, the British Red Cross runs fifty-four outpost hospitals, providing medical and nursing care for pioneer settlers in places to which ordinary hospitals have not yet penetrated. In Australia, tuberculosis is a great problem. The Red Cross has established seven sanatoriums and convalescent homes throughout the colony for returned soldiers and civilian patients and their families. An interesting feature is the provision of automobiles to enable disabled ex-soldiers to carry on their work. In India, child welfare is in the forefront of the Red Cross problem program. More than 200 child welfare centers have been opened. In the Madras Presidency alone nearly 1,000,000 mothers and children attended the centers in a year. Training is given to the dais (hereditary midwives), whose practices are often appalling. Health education is also carried on by means of films, lantern slides, posters, health and baby weeks and demonstration cars, which tour rural districts. After the great Assam flood last year, the Red Cross inoculated 50,000 persons and so prevented an outbreak of cholera. The South African Red Cross has developed an extensive scheme for the instruction in first aid, both of Europeans and of natives working in the Transvaal mines. Health vans tour the Kafir villages, giving lectures, and first-aid dressing stations are set up at important centers.

Birth Control Condemned

In a previous letter the carefully guarded tolerance of birth control under certain conditions in the encyclical letter issued by the seventh Lambeth conference of the archbishops and bishops of the Church of England was reported (The Journal, September 20, p. 874). But the Roman Catholic Church in this, as in other countries, condemns the practice absolutely. Its official head, Cardinal Bourne, Archbishop of Westminster, in a sermon said he would fail in his duty if he allowed to pass unnoticed the Lambeth pronouncement, "which condones in certain circumstances practices—euphemistically described as birth control—which Christian tradition has consistently condemned as unnatural sin. Lest any be led astray by this resolution of the Lambeth conference and placed thereby in danger of committing grievious sin, I now reaffirm the teaching of the Catholic Church on this subject, binding on the conscience of every man and every woman. Any direct interference with the natural consequence of the marital relation—namely, conception, whether within the marriage state or without it—is an unnatural vice, sinning against the nature which the Creator has bestowed on us."

A Great Pathologic Collection

The greatest pathologic collection made by one man since John Hunter laid the foundation of the Museum of the Royal College of Surgeons is the work of Dr. Cuthbert Lockyer, consulting gynecologist to Charing Cross Hospital, who has now presented it to the hospital. It consists of 3,000 obstetric and gynecologic specimens and is the finest of its kind in London. It represents the work of thirty years and is supplemented by 2,000 microscopic sections of the actual specimens displayed or of parallel conditions. Dr. Lockyer has written and published a catalogue, which has taken him five years to compile. He has also provided a donation of $2,500, the interest on which is to be used for the maintenance of the collection in its present perfect condition. The catalogue, of 297 pages, is so arranged as to act as its own index and contains comments that should be instructive to the student. The collection covers all the ordinary diseases of the female genital organs and includes many rare conditions. It should be valuable not only to the students of the hospital but to all investigators of these diseases.

PARIS

(From Our Regular Correspondent)

Oct. 15, 1930.

Meeting of the French Surgical Society

The thirty-ninth annual meeting of the Société française de chirurgie was held, October 6, in the Great Hall of the Faculté de médecine. The corridors, together with booths erected in the courtyard, were replete with exhibits of apparatus and equipment. The president was Dr. Auvray, agrégé professor at the Faculté de médecine de Paris and surgeon to the Hôpitaux de Paris, who was assisted by the vice president, Professor Lambret of Lille, and by the general secretary, Dr. Grégoire. It has been the custom to appoint each year, as the honorary president, a national figure who, though not a medical man, has shown interest in medicine. Maréchal Joffre, Maréchal Lyautey and others have been accorded that honor. This year Mr. Paul Bourget, whose plays and stories contain many allusions to physiologic psychology and who has shown, all his life, a great predilection for medicine, was thus distinguished. He has always expressed regret that he did not become a physician. He took courses in surgery at Maisonneuve, later visited the clinics of Dieulafoy, and today, at the age of 76, he frequents the dispensaries for abnormal children. His opening address abounded in wit, although it was philosophic in tone. He exalted in the surgeon the necessary combination of thought and action, the former illuminating the latter, which may be generalized and taken as a maxim of life itself. The active president, Mr. Auvray, discussed in his inaugural address the need of creating in France, as well as in the United States and in England, a body of professional anesthetists. Often, in hospitals, anesthesia is entrusted to inexperienced students. Auvray recalled with regret the deaths of several members of the society during the past year, particularly Tuffier, Lecène, Souligoux and Delagénière. The scientific work of the congress comprised the study of three selected topics and of a number of unofficial communications presented by surgeons in the provinces and in foreign countries. In general, the surgeons of Paris are not so widely represented at this congress, although it always meets in Paris, either with the idea of leaving a freer hand to their guests or because the weekly discussions before the Société de chirurgie are found to be adequate. On the other hand, all the morning, in their hospital services and in the large clinics, they give operative demonstrations for the edification of their colleagues visiting Paris and, if occasion arises, even allow their services to be used by eminent foreign surgeons for demonstrative purposes. For instance, Dr. Pierre Rhéaune of Montreal gave a demonstration of his method of performing gastrostomy. Among other representatives from foreign countries who were in attendance may be mentioned Professors Sionard of the University of Quebec, Archibald Young of Glasgow, Lozano of Saragossa, and Alessandri, Diminici and Galeazzi of the universities of Italy.

KÜMMELL'S DISEASE, OR POSTTRAUMATIC SPONDYLITIS

The introductory paper on the first official topic was presented by Drs. Froelich of Nancy and Mouchet of Paris, who discussed the merits of the several names for the disease: rarefying osteitis of the vertebral bodies, posttraumatic disease of the spinal column, posttraumatic deformation of the vertebrae, and others. As to the pathogenesis, the prevailing idea is that of an unrecognized fracture, with hematoma and local denutrition of the bone. The researches of Schmorl of Dresden have contributed much toward the elucidation of the condition. The vertebral depression is due to the fact that the patients, after a slight traumatism, experience no pain and continue to walk. To this must be added the effect of the intervertebral disk, which often manages to break through the interior of the bone tissue and to cause a general disorganization. As Leriche views it, Kümmell's disease is only a special type of posttraumatic osteoporosis due to hyperemia. The authors referred to the growing frequency of this disorder. The war, with the disorder of trench life, automobile accidents with closed cars, and also railway accidents have greatly increased the number of cases. The disease, in 60 per cent of the cases, has its seat in the lumbar or dorsolumbar region. The diagnosis is often difficult in the beginning. The resulting deformation of the spine cannot be remedied other than by the application of a plaster cast and the wearing of a corset. The paper closed with a study of the question from the point of view of labor legislation and insurance.

Further communications on posttraumatic spondylitis were presented by Lozano of Saragossa; Julliard and Oltramare of Geneva; Alivisatos of Athens; Leriche of Strasbourg; Michel of Nancy; Jeanbrau of Montpellier; Proust, Judet, Peugniez, Roederer and Trêves of Paris; Guillaume-Louis of Tours; Rocher and Gourdon of Bordeaux; Leclerc of Dijon; Imbert, Rottenstein, Massini and Silhol of Marseilles; Termier of Grenoble; Perdu of Amiens, and Mencière of Reims.

PREPARATION OF PATIENTS FOR OPERATIONS

Two official papers were offered on "The Preparation of Patients for Operations," by Professor Lambret of Lille and by Dr. Louis Sauvé of Paris. The former dealt with the prevention of disorders due to anesthetics; the determination of the resistance of the patient to be operated on, by means of analyses to discover the functioning of the liver and the kidneys; the preparatory diet; the importance of hydration of the tissues (which led him to oppose absolutely previous purgation), and, finally, the peculiar part played by temperament and by the condition of the endocrine glands. Special consideration was given to diabetes, in which Lambret advised the use of insulin for the preparation of the patient; also to anemia due to previous hemorrhage, in which he recommended the transfusion of blood in order to mitigate the danger of pulmonary and cardiac complications. In fact, the paper dealt with operative results, with a view to preventing unfavorable sequels, as it did with preparatory care. Mr. Sauvé kept closer to the subject in hand and considered the various diathetic states; also diabetes, malaria, obesity, intoxications, tuberculosis and syphilis, from the point of view of the risks that the traumatism will impose on every patient of that type. In conclusion, Sauvé expressed his satisfaction that surgery is enlarging the field of knowledge by means of which operative risks may be diminished and that its rôle is rising above that of mere skilful manual workmanship.

These papers were followed by articles, on the same subject, by Archibald Young of Glasgow; Daniel of Bucharest; Neuman and Mayer of Brussels; Sciaky of Milan; Leriche of Strasbourg; Guyot and Jeanneney of Bordeaux; Chalier of Lyons; Vanverts of Lille; Lardennois of Reims; Heitz-Boyer, Sorel, Pauchet, Dupuy de Frenelle, Petit de la Villéon, Sénéchal and Finikoff of Paris; Masini and Rottenstein of Marseilles; Lefebvre of Toulouse, and Abadie of Oran.

CHRONIC PANCREATITIS

P. Brocq of Paris and G. Miginiac of Toulouse presented a paper on "Chronic Pancreatitis," which was a résumé of an inquiry by the authors among specialists in diseases of the biliary tract, throughout the world. They emphasized that chronic pancreatitis is frequently overlooked, its diagnosis often being due to a chance intra-abdominal exploratory operation; and it is often confused with cancer, even from the histologic point of view. The diagnosis is difficult even when the organ is in hand. Then there is the slowness of the evolution of the condition, with the many remissions and sometimes spontaneous recoveries. The pancreas is frequently subject, in an acute state, to the influence of typhoid, smallpox, diphtheria, pneumonia and mumps, and, in the chronic state, to the influence of tuberculosis and syphilis. One must take account also of the propagation of lesions in the adjacent tissues; more particularly, biliary lesions. As treatment, the liberation of the pancreas from the adhesions that unite it to the adjacent organs often suffices to bring about lasting relief. Partial excisions are dangerous.

SPECIAL COMMUNICATIONS

The numerous nonofficial communications comprised the whole domain of surgery, being presented, as already stated, by physicians from the provinces and from foreign countries. There was one posthumous paper by Dr. Delagenière, who died a few days before the session, dealing with the dangers of lumbar puncture in fractures of the cranium, and with the surgical treatment of cerebral hemorrhages. Dr. Heitz-Boyer and Dr. Moure each presented a paper on the advantages of the electrical knife in surgery. Heitz-Boyer, who utilized an excellent film for his demonstration, recommended that the diathermic knife be abandoned, as it adheres to the tissues in the same manner as the thermocautery. He prefers the knife driven by an interrupted high-frequency current, which allows frank and rapid sectioning, which is just as accurate as with the ordinary knife, and offers great facility in separating the planes of cleavage and in suppressing capillary hemorrhage. Hemostasis, according to Heitz-Boyer, is due to a thrombosis of the small blood vessels caused by the high-frequency current. Nevertheless, as a precaution, he applies a ligature to the more important vessels. Mr. Calot, orthopedist of Berck, announced new signs for detecting at an early date congenital luxations and subluxations of the hip in the new-born. He examines chiefly the site occupied by the head of the femur, which normally should correspond, in projection, to the middle of the line uniting the posterior iliac spine and the pubis. Mr. Jiano of Bucharest recommended a radical treatment for hemorrhoids by means of a special compressing device. Mr. Jeanneney of Bordeaux dealt with narrowing of the rectum due to the use of radium in that region. Young of Glasgow presented two cases of bone tumor treated by resection, together with a large graft. Arnaud and Ciando of Marseilles discussed retardation of consolidation of fractures through injection into the area of colloids of silica and lime. Ferey took up the advantages of the resection of the hypogastric plexus. Mr. Chosson gave his experience with intravenous injections of calcium chloride to remedy postoperative retention of urine.

Among the operative demonstrations given in the hospitals and clinics during the course of the congress, mention may be made of that of Dr. Victor Pauchet on surgery of the digestive tract; of Drs. Marion, Chevassu and Cathelin on the surgery of the urinary passages, and of Dr. Calot of Berck on the treatment of tuberculous osteitis, arthritis and adenitis by modifying injections, without surgical intervention, which Calot regards as always dangerous.

AUSTRALIA

(From Our Regular Correspondent)

Oct. 8, 1930.

The College of Surgeons

Arrangements are being made for the primary fellowship examination of the Royal College of Surgeons of England, to be held in Australia in August or September, 1931, provided not less than twenty-five candidates are eligible.

Two examiners in anatomy and two examiners in physiology, who shall be present or past members of the board of examiners in anatomy and physiology for the fellowship, will be sent by the college from England. A professor of anatomy and a professor of physiology or such other persons as may be agreed on shall be appointed by the council from names submitted by the College of Surgeons of Australasia, to act as assessors for the examiners. The expected deficit on the examination shall be borne equally by the two colleges. The Royal College of Surgeons emphasizes the fact that the proposed scheme will be experimental only, and that it shall be free to decline to hold another examination in Australia without laying itself open to any suggestion of a breach of faith.

Considerable discussion both inside and outside the college has arisen over the rules for the conduct of fellows of the college:

1. The patient, or the person legally responsible for him, must consent in the choice made of a surgeon to perform the operation. It is to be noted that such a consent would be an essential factor in the successful suit by a surgeon for the recovery of his fee.

2. Having been selected by the patient, the surgeon is personally responsible to him for the operation. He is also responsible for, and shall conduct, the postoperative treatment, except by special arrangement with the patient.

3. The surgeon must render his account direct to the patient.

4. The surgeon must not accept his fee for an operation from the practitioner in charge of the patient, unless the surgeon forwards a receipt for the fee received direct to the patient.

5. If circumstances compel the surgeon to delegate the postoperative treatment of a patient to another practitioner, the latter must collect the fee for so doing direct from the patient. The surgeon must not pay the practitioner in charge of the patient a fee for conducting the postoperative treatment.

6. Separate accounts for the assistant, anesthetist or other necessary services must be sent to the patient, or the surgeon must state on his account form the exact amounts due for these services.

7. The assistant's standard fee shall be not more than one eighth of the operation fee, or, alternatively, not more than five guineas. When, owing to special circumstances, the assistant's fee is larger than this amount, the assistant must render his own account on his own account form.

8. The anesthetist's standard fee shall not be more than one eighth of the operation fee, or, alternatively, not more than five guineas. When, owing to special circumstances, the anesthetist's fee is larger than this amount, the anesthetist must render his own account on his own account form.

9. It is desirable that the practitioner in charge of the patient should be present at an operation on his patient. Should he have to travel any considerable distance for this purpose, the patient must be informed beforehand of the extra fee involved.

It was unfortunate that a tactless discussion on fee splitting should have been carried out in the columns of the lay press in Melbourne soon after the publication of these rules. One of the reasons for the commencement for the publication of the new medical journal, the *G. P.*, was this published attack on the ethics of the general practitioner.

A New Medical Journal

The general practitioners' section of the British Medical Association in Victoria, considering that its interests were not sufficiently served by the *Medical Journal of Australia*, has commenced publishing a journal of its own which has the terse title the *G. P.* The field that the journal covers is the reverse of academic. It deals mainly with problems of everyday general medical practice and medicopolitical development that affects the general practitioner. Original articles dealing with medical research are not included in the scope; the journal aims to act as a monthly refresher for the general practitioner on modern technic in diagnosis and treatment.

The journal is published monthly and has an Australia-wide circulation. It has had a most encouraging reception and the outlook seems to be that it will overcome the rigors of the neonatal period. The journal has adopted rather a strong attitude toward the activities of the College of Surgeons of Australasia. Some misunderstanding developed during the annual congress of the college in Melbourne early this year, and the general practitioners section took strong exception to the attitude which the college adopted toward the general practitioners.

The *G. P.* considers that the college is unsurping the position which the British Medical Association in Australia occupies as the corporate body of medical thought and action in Australia.

Diphtheria Immunization in Australia

Since the fatalities following on diphtheria immunization of children occurred at Bundaberg, Queensland, in January, 1928, when twelve children died within forty-eight hours of inoculation, the whole question of diphtheria immunization has been in abeyance. Publicity was given to the fatalities at the time and as a natural result the people were averse to subject their children to immunization. It must, unfortunately, be admitted that the report of the royal commission appointed to inquire into the cause did not completely satisfy the public as to the future safety of the process. It was a surprise to bacteriologists and clinicians also that staphylococci could provoke so fulminating an illness on subcutaneous injection. The illness did not resemble the ordinary clinical forms of staphylococcal septicemia but was an acute intoxication which either ended fatally or was overcome within a day or two in the patients who recovered. Further, as judged by animal experiments, the strain isolated was by no means that of an exceptionally virulent staphylococcus.

Recent work by Burnet and Kellaway at the Walter and Eliza Hall institute, Melbourne, on staphylococcal toxin showed that a definite exotoxin is produced by all the pyogenic staphylococci and is in all cases qualitatively identical, although varying quantitatively in differing strains. They considered that the Bundaberg tragedy shows that under certain conditions large amounts of staphylococcal toxin can be elaborated from the human body, causing death in a manner that they were able to reproduce in their experiments on animals.

The public was loath to adopt diphtheria immunization, and health, municipal and school medical authorities were tacitly agreed that the subject had better be dropped. It came as a surprise, therefore, when in May of this year the lay school committee at Virginia, near Brisbane, Australia, asked for the children to be immunized in the face of a diphtheria epidemic that was raging. This request coincided with the issue by the Commonwealth Serum Laboratories of a formaldehyde-treated diphtheria prophylactic anatoxin. The technic used in the immunization was to give the children a Schick test and at the same time to do a skin test using 0.1 cc. of a 1:20 dilution of the anatoxin. The Schick positive and anatoxin negative children were then immunized with anatoxin.

Some 200 children were thus treated without untoward effects and although no fresh requests for immunization by other communities have been made to date it is considered that the public confidence in the process has increased, especially in view of the fact that a different method from that used at Bundaberg is now being employed. A sharp epidemic of diphtheria will soon awaken the demand for immunization.

RIO DE JANEIRO

Oct. 15, 1930.

The Roentgenographic Picture in Tuberculosis

Dr. M. de Abreu recently lectured before the Academia Nacional de Medicina on the characteristic roentgenographic picture observed in pulmonary tuberculosis. The lesion of pulmonary tuberculosis, as represented by a spot in the roentgenogram, has a rapid development till it reaches the so-called total limit of volume for the initial period of tuberculosis. Then its development follows one of three forms of evolution: (1) The lesion may continue in a slow development (chronic tuberculosis); (2) the development of the lesion may stop and in this case the spot that represents the lesion has the same size whenever a new picture is taken; (3) the lesion may recede. The spot on the picture then appears smaller and smaller at the following roentgen examinations, till it disappears completely as the lesion is absorbed. In roentgenograms taken of patients with pneumonia it is observed that the lesions in the lung, as represented by the spot in the picture, show a constant development in size up to the seventh day. Then the lesion enters a stationary period during twenty-four or forty-eight hours and from then the lesions recede till the twelfth or fourteenth day of the disease. In cancer and in aneurysm the roentgen spot shows a constant development of the lesion during a period of twelve months. This development is rapid in cancer and slow in aneurysm. The speaker illustrated his lecture by showing charts of the curves of evolution of the lesion observed in different cases of tuberculosis, aneurysm, cancer and pneumonia.

Domestic Animals as Carriers of Yellow Fever

Dr. J. Lemos Monteiro presented before the Sociedade de Medicina e Cirurgia de São Paulo the results of experiments made in animals with the aim of determining the rôle of domestic animals as carriers of yellow fever. On inoculation into dogs, the yellow virus seems to keep its virulence in the organism of the animals for some days, so that on reinoculation into a rhesus monkey it causes a febrile reaction. Inoculation of the virus of yellow fever into cats causes, after a period of incubation, fever and other symptoms. Blood withdrawn from cats after twelve days of their attack of experimental fever, and injected into normal rhesus monkeys, causes a typical attack of yellow fever. At the end of thirty days the virus from the cat still is able to provoke the immunity of the rhesus monkey against a further inoculation of the virus. The author's results confirm those of Bauer and Mahaffy, which were obtained by means of the inoculation of certain African monkeys, and they point out the importance of domestic animals as carriers of the virus of yellow fever.

Bacillemia in Leprosy

Dr. Nelson de Souza Campos of São Paulo published recently a paper on bacillemia in leprosy in which he reported the determination of bacillemia on 100 patients with various forms of leprosy. He obtained positive results in fifty-five cases and doubtful results in eight cases. In tuberculous and mixed forms of leprosy, bacilli were found in the blood in a high rate (87.5 and 73.8 per cent, respectively) of the cases observed. In the nervous and maculo-anesthetic forms of leprosy, bacilli were found in the blood in a small percentage. The high content of bacilli in the blood of patients with tuberculous and mixed forms of leprosy points out the greater danger of contagion of these forms of leprosy over the other forms, and the necessity of a more intense campaign in hygiene and prophylaxis against them.

Intestinal Obstruction Caused by Ascarids

Dr. Motta Mais reported recently the case of a girl, aged 3, who presented a clinical picture of peritonitis and intestinal obstruction. An exploratory laparotomy revealed a large amount of green, flocculent and putrid liquid in the abdomen. Parts of the ileum were dilated and a mass of white cords was seen inside, which on examination proved to be bundles of ascarids. The ileum was gangrenous in places. An enterostomy was performed and a large number of ascarids removed. About 20 cm. from the first occlusion there was another mass formed by a bundle of ascarids. Ninety-two worms were removed. The smallest parasites were 15 cm. and the longest 30 cm. long.

UKRAINE

(From Our Regular Correspondent)

Odessa, Oct. 20, 1930.

Conference of Physiologists

The fourth conference of physiologists, held in the city of Charkov, May 20-26, was characterized by many interesting reports. In the plenary sittings of the conference much attention was paid to the questions of weariness and nutrition. Papers were read by Professor Kekcheev of Moscow on "Weariness and Methods for Its Study"; Professor Kagan of Charkov, "Energetics of Work and Weariness"; Professor Bernstein of Moscow, "The Present Biomechanical Method and the Study of Weariness." Professor Palladine of the Ukrainian Biochemical Institute, Charkoff, in his report on "Biochemistry and Weariness," explained the biochemical processes that take place in the brain, during the state of weariness.

The session gave much attention to questions of nutrition. "Albumin Problems in Nutrition" was discussed by Professor Zbarsky of Moscow, and "Vegetables and Canned Vegetables as a Source of Vitamins" by Professor Cherkess of Odessa. Other reports were concerned with the organization of public nutrition. According to the five year plan of construction of the Soviet Union, it is proposed to open so many eating houses and like establishments that, before the end of the year 1933, half of the population will get their food there. The scientific study of all questions connected with public nutrition has begun only recently, and at this conference these questions were considered for the first time. Therefore, in its resolution the session made a special point as to the solving of the problem of public nutrition in the shortest possible time.

The conference was much interested in the paper of Professor Zeleny of Leningrad on "The Rôle of Subcortical Centers," which was accompanied by moving pictures. The author, experimenting on dogs which had their cerebrums removed by the Holz method, worked out conditional reflexes, defensive and phonetic. These dogs also could differentiate the sources of irritation. Professor Zeleny thinks that even a total absence of conditional reflexes in animals that have no pallium does not prove that normal animals have no associative centers in their subcortical centers.

Dr. Brouchanenko of Moscow demonstrated to the conference his preparation of a dog's head separated from its trunk. By joining the head of a dog, separated from its trunk, to a system of pumps and apparatus for keeping up artificial circulation and breathing, the author found that this head maintains for about five or six hours a series of central nervous functions. It maintains reflexes from the peripheral apparatus and has its automatic reactions of an endogenous character. The dog's head separated from its trunk keeps the winking reflex, when the eyelid or cornea is touched. The change of oxidation in blood brings forth yawns, a wide opening of the mouth and other manifestations analogous to suffocation. They disappear when oxidation is improved. When it is stopped, the dog's head shows manifestations of agony and death.

In the section of biochemistry, the foreign guests were Professor Thomas of Leipzig and Professor Winterstein of Breslau, whose papers were of great interest to the soviet physiologists. The next conference will be held in Tiflis (Caucasus) in 1932.

The Campaign Against Cancer in Ukraine

The progressive increase in the Ukrainian Socialist Soviet Republic is a fact that attracted the attention of physicians even at the time when the country was beginning to recover after the civil war. The Surgical Society of Odessa in 1922 was the first in Ukraine to raise the question about taking proper measures. Four years later in Moscow the first all-union conference to consider means of combating cancer took place. Because of a deficiency of resources it was impossible then to realize the plans proposed. Until recently, the combat against cancer has not come out of the limits of individual investigations and experimental work. Only this year has it been placed on a solid basis. According to the plan of the people's commissariat of health, the whole country will be divided into four districts, in each of which there will be organized an institute for the study of cancer. There already exists such an institute in Charkov and soon similar institutes will be opened in Kiev, Odessa and Dniepropetrovsk (formerly Ekaterinoslav).

The roentgen-radiologic institute for the study and prevention of cancer will comprise: 1. A scientific department (theoretical and experimental), which will study the origin of cancer and give attention to the correlation between cancer and professional diseases. 2. A clinical department for administering aid to patients by surgery and by radium and roentgen rays. 3. A pedagogic department to give special courses for physicians, where methods of early diagnosis and cure will be studied. 4. A special department to organize public lectures and theatrical plays, to publish posters and popular pamphlets and books, and to issue moving pictures with the aim of popularizing the struggle against cancer. The "Ukraine film," a state organization, will undertake in Odessa, work in conjunction with this department of the anticancer institute, on popular films and also scientific films for physicians. 5. The statistical department, which will collect the result of the work of the district institute and of the country and district anticancer stations. The latter will be formed in every rural hospital. The statistical department will not only receive all the materials from these institutions but compile genealogical lists of cancer patients. An all-union anticancer session will be held in Charkov in February, 1931. Its aim is to coordinate all the means of fighting cancer.

BERLIN

(From Our Regular Correspondent)

Oct. 20, 1930.

Eugenics and the Birth Rate

In the beginning of the eugenic movement, eugenists in America decided to make experiments to discover whether hereditary taints or defects could be eradicated by control measures. As Dr. Scheumann recently brought out at the meeting of the Vereinigung öffentlicher Eheberatungsstellen, in Dresden, eugenists demanded, at that time, that persons who, with pathologic hereditary tendencies, were a menace to future offspring, should be prohibited from marrying. Marriage should, it was urged, be made dependent on the securing of a special permit. The expectations aroused by these measures were not, however, realized. Those concerned avoided the issue by marrying in another state in which no such restrictions were known: or, if possible, they concealed their disease. Many eugenists in Germany supported the view that the presentation of a certificate as the basis for securing a marriage license was not only desirable but necessary. The Prussian ministry of public welfare, in 1926, by an order addressed to the district health officers, advocated the creation of examination centers for the issuance of marriage permits. No force could be used to compel marriage candidates to submit to a medical examination, as there was no basis in the federal laws for such a measure. Other eugenists followed a different course. Instead of seeking the enactment of new laws, they sought to clarify the minds of the masses by endeavoring to strengthen the feeling of responsibility for their own health and the health of their offspring. This trend received the endorsement of Dr. Scheumann, who conceived of a comprehensive biologic consultation of adults both before and during marriage, and recommended that certification be placed in the hands of physicians and that the various welfare centers be brought under one uniform system. He referred to Saxony, which, in 1927, brought the marriage consultation centers into a uniform system with public welfare. The marriage consultation centers in Saxony have achieved good results because they rest on voluntary acquiescence. Thus, Professor Fetscher, the director of the municipal marriage consultation center in Dresden, reported that, in three years, out of 2,200 applicants, he was able to induce feebleminded or mentally ill persons, in 123 cases, to renounce the idea of having children, and many of them submitted to sterilization.

A service was rendered by Prof. Robert Wilbrandt, of the Dresdener Technische Hochschule, who pointed out the connection between the decline in the birth rate and the existing economic status. It has been found that immoderate wealth is not conducive to an increase in the birth rate. However, it must be recalled that modern medical technic now affords wide circles the opportunity of limiting the number of children in a family. It has become the "custom" to have only one child or even none. In southern France there are said to be areas that are almost depopulated, and it is well known that childless peasant couples often go to Switzerland to select an heir to their property. It is evident that the birth rate is closely connected with economics. Germany still has a large population in relation to its resources. It is in a critical position, from which it can be rescued only in case the world's markets, through reductions in tariff duties, are thrown open to export trade to a greater extent than at present, and thus enable it to accumulate capital. Something must be done to increase the supply of intellectual leaders, for only those who possess preeminent physical and mental equipment can maintain themselves in the economic struggle. All others must, sooner or later, become dependent on community or state aid.

It follows that our existence depends on the begetting of outstanding individuals possessing valuable hereditary qualities, for whom, then, the most favorable world environment must be created.

At present, Germany lacks all the preconditions for increasing the birth rate. While the total value of Germany's exports reaches a respectable sum, it is bought, nevertheless, through the nationalization of production, which, in turn, produces at times a vast army of jobless men. Duties, instead of declining, are being increased. The accumulation of capital has become much more difficult. Instead of endeavoring constantly to improve the quality of our schools and thus lay the foundation for the training of intellectual leaders, public education in the rural districts is being neglected. It is not surprising, therefore, that, in closing his address, Wilbrandt expressed himself in these terms: "If we consider soberly and dispassionately the present status of economic affairs in Germany, we are forced to conclude that, as a matter of fact, it is indeed fortunate that the population of the country is increasing so slowly."

Meeting of Psychoanalytic Society

At the second session of the Deutsche psychoanalytische Gesellschaft in September, in Dresden, two introductory public addresses preceded the scientific work of the session. Dr. Meng of Frankfort-on-Main spoke on "Psychic Hygiene on a Psychoanalytic Basis." He gave a summary of the service that psychoanalysis performs for the modern physician and the teacher in his relation with his protégés. Frau Dr. Horney of Berlin delivered an address on "The Mutual Distrust of the Sexes," which awakened great interest. What she presented had special value, for in her were combined the physician, scientifically trained, and a woman who was familiar with the emotions and feelings that are peculiar to her sex. In the scientific sessions, Dr. Boehm and Dr. Fenichel of Berlin discussed the Edipus complex. The titles of these addresses were: "The History of the Edipus Complex" and "Special Forms of the Edipus Complex," respectively. Dr. Reich of Vienna dealt with "Psychoanalysis and Character Formation," and Dr. Landauer of Frankfort-on-Main discussed "The Individual and His Fellowships." In the evening there were two more public addresses, by August Aichhorn of Vienna on "Guidance in Educational Matters," and Groddeck of Baden-Baden on the "Struwelpeter," which, for more than fifty years, has afforded amusement to countless German children. The "Struwelpeter," written by a physician by the name of Hoffmann, is a picture book with charming verses, adapted with great skill to the child's understanding. Even this charming book has to be dissected by the psychoanalysts!

Industrial Hygiene Society

At the annual session of the Deutsche Gesellschaft für Gewerbehygiene, in Breslau, September 24-25, the chief topic on the program was "Determination of the Degree of Disability in Occupational Diseases." The official paper on "Determination of Degree of Disability in Severe Pneumonoconiosis" was presented by Reichmann of Bochum, who described the development of the disease as revealed by the roentgenogram, and its diagnostic differentiation from tuberculosis. He reported statistics on the association of silicosis and tuberculosis. The mild cases of silicosis presented 8.7 per cent of tuberculosis; the severe cases, 30 per cent. However, tuberculosis was present in 75 per cent of severe cases of silicosis that came to necropsy. The clinical symptoms of pneumonoconiosis are comparatively insignificant. The degree of disability is determined by the functioning of the lung and the earning capacity of the examinee. In severe silicosis, the compensation should be at least 50 per cent of the total. If severe pneumonoconiosis is associated with tuberculosis, the latter becomes, in matter of fact, a compensable disease. The regulations concerning the granting of compensation for severe pneumonoconiosis should be extended to further industries.

Jadassohn and Mayer of Breslau offered a paper on the second official topic, "Determination of Degree of Disability in Skin Diseases of Industrial Origin." Most eczemas are of industrial origin. Next in order come the effects of rays and cancer-like changes. The delimitation of eczema as a disease entity was discussed. Industrial eczemas are due for the most part to hypersensitiveness, which is seldom congenital but is acquired in the industries through sensitization. The so-called incubation time varies within broad limits—up to ten years and more. Industrial eczemas are not in themselves characteristic. In the search for the offending substance, the irritants proposed by Jadassohn are useful. They are best employed in a suitable clinic. On the basis of the existing laws, only a few skin diseases of industrial origin are compensable. Hypersensitive persons are granted a compensation for loss of time resulting from the need of changing their occupation. Intimate contact with tar, pitch and arsenic may cause, in addition to eczemas, also sensitization to light and cancerous changes.

Cobet of Breslau followed Jadassohn and Mayer, and discussed the determination of the degree of disability in infectious diseases affecting the personnel in attendance on the sick. Of the acute infectious diseases, the most important are scarlet fever and diphtheria—but also sore throat with its sequels. Even in pneumonia, the possibility of infection cannot be denied. Proof of negligence does not entail loss of right to compensation. Certain difficulties are encountered in connection with claims for compensation owing to alleged indirect infection through contact with inanimate objects or germ carriers. In every case, the facts must be carefully inquired into in order to determine the possibility of disease. Germ carriers are not entitled to compensation, as they are not sick; they may not be able to continue in their regular occupation, but they are not otherwise incapacitated. Of the chronic infectious diseases, tuberculosis occupies first place. The possibility of a previously existing latent infection makes more difficult the demonstration of an occupational contamination. A thorough roentgenologic examination of the personnel on entering a new service will in the future make the determination of the degree of disability much easier. Next in order come syphilis, gonorrheal conjunctivitis and trachoma.

Marriages

FRANCIS M. B. SCHRAMM, Johnstown, Pa., to Mrs. Jane Brooks Staman of Mount Pleasant, September 22.

PHILLIP H. SIGRIST, New Philadelphia, Ohio, to Mrs. Lillian M. Ganiard of La Grange, Ind., October 22.

HARRY EVERETT ALDERSON, San Francisco, to Miss Cordelia Church Bishop, in Oakland, September 26.

HAROLD D. VAN SCHAICK, Jacksonville, Fla., to Miss Maude Coney of Savannah, Ga., September 10.

CHARLES PATTERSON ELDRIDGE to Miss Lucy C. Cheatham, both of Raleigh, N. C., September 28.

RICHARD OLNEY RUSSELL to Miss Louise B. Taylor, both of Birmingham, Ala., October 23.

ELBERT W. JACKSON, Paducah, Ky., to Miss Eleanor Johnson of Kansas City, Mo., October 3.

NORMAN L. SCHMIDT, New York, to Miss Dorothy Fain of Nashville, Tenn., August 13.

WENDELL A. KILLINS, Omaha, to Miss Genevieve Quale of Rochester, Minn., October 4.

WILLIAM ROY DILLINGHAM to Miss Zara Simpson, both of Salina, Kan., August 1.

Deaths

Edgar J. George, Chicago; Chicago Homeopathic Medical College, 1890; Hahnemann Medical College and Hospital, Chicago, 1905; formerly professor of ophthalmology, Hahnemann Medical College and Hospital; member of the American College of Surgeons; aged 67; on the staff of the Chicago Memorial Hospital, where he died, October 21, of coronary thrombosis.

Frederic D. Huntington Coerr, New York; Columbia University College of Physicians and Surgeons, New York, 1904; member of the Medical Society of the State of New York and the American College of Surgeons; served during the World War; on the staff of the New York City Hospital; aged 55; died, October 9, at Metuchen, N. J., of heart disease.

William Weed Van Baun, Philadelphia; Hahnemann Medical College of Philadelphia, 1880; professor emeritus of pediatrics at his alma mater; formerly on the staffs of the Hahnemann Hospital, West Philadelphia Homeopathic Hospital, Woman's Southern Homeopathic Hospital and St. Luke's Hospital; aged 72; died, October 6, of cerebral hemorrhage.

John Philip Gilligan, O'Neill, Neb.; Albany (N. Y.) Medical College, 1890; member and past president of the Nebraska State Medical Association; formerly secretary of the Holt County Medical Society; state senator, 1906-1908; for eighteen years member of the school board; at one time mayor; aged 63; died, September 28, of progressive muscular atrophy.

Ernest Lewis McEwen ⊕ Chicago; Rush Medical College, Chicago, 1897; associate clinical professor of dermatology at his alma mater; member of the American Dermatological Association; on the staffs of St. Francis Hospital, Evanston, Home for Destitute Crippled Children and the Presbyterian Hospital, Chicago; aged 63; died, October 30, of heart disease.

Henry Arnold Alderton, Palo Alto, Calif.; Medical Department of Columbia College, New York, 1885; member of the American Otological Society; formerly on the staffs of the Brooklyn Eye and Ear Hospital, Kingston Avenue Hospital, Kings County Hospital, and the Bushwick Hospital, Brooklyn; aged 66; died, September 30, of arteriosclerosis.

Richard Mark Brown ⊕ Ogden, Utah; Columbia University College of Physicians and Surgeons, New York, 1911; member of the American Roentgen Ray Society and the Radiological Society of North America; served during the World War; aged 45; died, September 12, in a hospital at Salt Lake City, following an operation for cholelithiasis.

Edward S. Kelly, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1897; member of the Louisiana State Medical Society; chief of the sanitary division of the city board of health; formerly a druggist, and member of the parish school board; aged 61; died, October 2, of chronic myocarditis and nephritis.

John Donald MacRae ⊕ Asheville, N. C.; University of Nashville (Tenn.) Medical Department, 1897; member of the Radiological Society of North America and the American College of Radiology; president of the Buncombe County Medical Society; aged 56; died, September 6, of injuries received in an automobile accident.

Charles Albert Bigler, Jr., Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1902; formerly professor of rectal diseases at his alma mater; member of the American College of Surgeons; aged 55; died, August 15, in the U. S. Naval Hospital, of carcinoma of liver, chronic arthritis and myocarditis.

Walter Lowrie Hunt, Bangor, Maine; Medical Department of Columbia College, New York, 1875; member of the Maine Medical Association; past president of the Penobscot County Medical Society; on the staff of the Eastern Maine General Hospital; aged 81; died, June 10, of carcinoma of the pancreas and liver.

Marcus Duke Smith, Cambridge, Md.; University of Maryland School of Medicine, Baltimore, 1914; served during the World War; formerly on the staff of the Cambridge Hospital; aged 38; died, July 25, in the U. S. Veterans' Hospital, Oteen, N. C., of pulmonary tuberculosis and tuberculous laryngitis.

Stephen Cambreleng Powell, Newport, R. I.; Yale University School of Medicine, New Haven, 1864; Medical Department of Columbia College, New York, 1864; member of the Rhode Island Medical Association; on the staff of the Newport Hospital; aged 87; died, in October, of chronic myocarditis.

Thomas Franklin Dornblaser ⊕ Amboy, Ill.; Medical Department of the University of Illinois, Chicago, 1908; veteran of the Spanish-American War; formerly member of the school board; one of the medical directors of the Amboy Public Hospital; aged 51; died, September 28, of heart disease.

Emery Szamosi ⊕ Bridgeport, Conn.; University of Budapest, Hungary, 1919; served during the World War; on the courtesy staffs of the Bridgport Hospital and St. Vincent's Hospital; aged 34; died, September 18, of septic arthritis, endocarditis and pulmonary embolism.

William Frederick Brooks, Bagwell, Texas; University of Michigan Homeopathic Medical School, Ann Arbor, 1888; member of the State Medical Association of Texas; aged 68; died, June 29, in Battle Creek, Mich., of aortic insufficiency, hypertension and arteriosclerosis.

Robert Thurlow Hood ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1914; member of the American College of Physicians; served during the World War; aged 43; on the staff of the Western Pennsylvania Hospital, where he died, October 5, of psoas abscess.

Charles Eugene Perry, West Hartford, Conn.; Tufts College Medical School, Boston, 1909; member of the Massachusetts Medical Society; formerly superintendent of the New Hampshire State Sanatorium, Glencliff; aged 47; died, July 26, in Hartford, of heart disease.

George W. Kinard, Leacock, Pa.; Jefferson Medical College of Philadelphia, 1887; member of the Medical Society of the State of Pennsylvania; aged 69; died, September 19, in the Lancaster (Pa.) General Hospital, following an operation for hypertrophy of the prostate.

John Philip Nicodemus, Indianapolis; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; member of the Indiana State Medical Association; served during the World War; aged 47; died, October 8, of a self inflicted bullet wound.

Frederick Percy Lawton, Traverse City, Mich.; University of Michigan Medical School, Ann Arbor, 1897; member of the Michigan State Medical Society; member of the school board for twelve years; aged 60; died, September 27, of intestinal obstruction.

Julius Clegg Hall ⊕ Albemarle, N. C.; University College of Medicine, Richmond, 1899; secretary and past president of the Stanley County Medical Society; aged 56; on the staff of the Yadkin Hospital, where he died, October 3, of streptococcic sore throat.

William J. Madsen ⊕ Millers Falls, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1920; Missouri College of Medicine and Science, St. Louis, 1922; aged 45; died, July 17, in Boston, of carcinoma of the rectum.

William Allen Bush, Winchester, Ky.; Kentucky University Medical Department, Louisville, 1905; member of the Kentucky State Medical Association; served during the World War; aged 60; died, September 28, of acute nephritis.

Lewis Samuel Dietrich, Stevens Point, Wis.; Northwestern University Medical School, Chicago, 1906; member of the State Medical Society of Wisconsin; aged 59; died, September 22, of nasal hemorrhage and prostatectomy.

William A. Pitzele, Lorain, Ohio; University of Illinois College of Medicine, Chicago, 1903; member of the Ohio State Medical Association; on the staff of St. Joseph's Hospital; aged 53; died, November 1, of uremia.

Charles M. Sebastian, Martin, Tenn.; University of Louisville (Ky.) School of Medicine, 1870; member of the Tennessee State Medical Association; aged 80; died, September 28, of pernicious anemia and arteriosclerosis.

Isaac Deering Harper, South Windham, Maine; Medical School of Maine, Portland, 1885; member of the Maine Medical Association; aged 70; died, August 4, in Gorham, of chronic myocarditis and coronary thrombosis.

Alphonso Nelson Witham, Westbrook, Maine; University of Vermont College of Medicine, Burlington, 1885; member of the Maine Medical Association; aged 72; died, August 13, in a local hospital, of arteriosclerosis.

William C. Lipscomb, Crockett, Texas; University of Louisville (Ky.) School of Medicine, 1883; Medical Department of the University of Louisiana, New Orleans, 1891; aged 73; died, October 1, of carcinoma.

William Thomas Chinn, Wellsburg, Iowa; College of Physicians and Surgeons, Keokuk, 1890; aged 78; died, October 5, in the Ellsworth Hospital, Iowa Falls, following an operation on the gallbladder.

Edward Wier Smith ⊕ Meriden, Conn.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1882; member of the American College of Surgeons; aged 76; died, October 8, of coronary thrombosis.

John Nicol Vroom ⊕ Denver; Denver College of Medicine, 1889; Rush Medical College, Chicago, 1890; aged 65; died, August 3, in St. Joseph's Hospital, of carcinoma of the duodenum.

Robert Gustav Boehm, Chicago; Loyola University School of Medicine, Chicago, 1916; aged 38; was killed, October 22, when the automobile in which he was driving was struck by a street car.

Almon S. Shafer, Columbia, Iowa; State University of Iowa College of Medicine, Iowa City, 1889; aged 72; died, September 25, in Solon Springs, Wis., of carcinoma of the prostate.

Stanley Sevier Warren, Columbus, N. M.; University of Pennsylvania School of Medicine, Philadelphia, 1894; aged 59; died, September 24, in Los Angeles, Calif., of chronic myocarditis.

Edward Kirby Morris ⊕ Merrill, Wis.; Rush Medical College, Chicago, 1894; on the staff of the Holy Cross Hospital; aged 63; died, August 26, of chronic nephritis and myocarditis.

Peter J. Koerper, Wilmette, Ill.; Rush Medical College, Chicago, 1903; Spanish-American War veteran; aged 52; died, September 14, of cirrhosis of the liver and chronic nephritis.

Michael Coleman Ryan, Coaldale, Pa.; Jefferson Medical College of Philadelphia, 1888; aged 76; died, May 17, in the Hazleton (Pa.) State Hospital, of carcinoma of the neck.

David Bruce Anderson, Paris, Ky.; Louisville Medical College, 1902; member of the Kentucky State Medical Association; aged 53; was accidentally drowned, October 3.

William Arthur Martin, San Francisco; Universität Heidelberg Medizinische Fakultat, Heidelberg, Baden, Germany, 1882; aged 74; died, September 7, of heart disease.

Walter Edwin Walker ⊕ Burlington, N. C.; Medical College of Virginia, Richmond, 1903; aged 50; died, October 3, in a local hospital, of cerebral hemorrhage.

Alfred Vincent Wepfer, Oakland, Calif.; Stanford University School of Medicine, San Francisco, 1923; aged 47; died, August 4, in Yreka, of appendicitis.

John Edwin Stillwell ⊕ New York; Medical Department of Columbia College, New York, 1875; aged 77; died suddenly, October 6, of coronary thrombosis.

Althea Edmund Bradshaw, Halo, Ind.; Kentucky School of Medicine, Louisville, 1878; aged 80; died, September 6, of carcinoma of the stomach.

Byron Leaford Hale, Cherryvale, Kan.; Kansas Medical College, Topeka, 1900; aged 64; died, September 17, of carcinoma of the prostate.

James Thomas Carter, Walhalla, Texas; Medical Department of the University of Louisiana, New Orleans, 1878; aged 75; died, June 24.

Charles Herbert Lowell ⊕ Carmel, Calif.; Cooper Medical College, San Francisco, 1896; aged 55; died, July 30, at Port Lobos Gate.

James Egbert ⊕ Indianapolis; Medical College of Indiana, Indianapolis, 1898; aged 59; died, October 8, of uremia and acute nephritis.

Edward R. Fletcher, Decoto, Calif.; Rush Medical College, Chicago, 1870; aged 85; died, August 6, of chronic myocarditis.

John Hazlewood, New Albany, Ind.; Kentucky School of Medicine, Louisville, 1883; aged 66; died, August 26, of lobar pneumonia.

Henry Logan Giles, Chicago; University Medical College of Kansas City, Mo., 1896; aged 57; died, July 24, of arteriosclerosis.

Leander Zebina Skinner, Loudonville, Ohio; Baltimore Medical College, 1894; aged 63; died, October 10, of angina pectoris.

Nathan Kaufman, Brooklyn; Long Island College Hospital, Brooklyn, 1915; aged 47; died, October 1, of hypostatic pneumonia.

James Gillespy Strawn, St. Louis; Meharry Medical College, Nashville, Tenn., 1923; aged 46; died, July 31, of sunstroke.

Gavin Shearer Herbert ⊕ Los Angeles; College of Medicine and Surgery, Chicago, 1909; aged 44; died, August 12.

Robert Creswell Black, Denver; Emory University School of Medicine, Atlanta, 1917; aged 42; died, August 28.

THE DUGDALE LIBEL SUIT

Frederick Dugdale, Abrams and Koch Disciple, Loses His Libel Suit Against the Lowell Sun

Frederick Dugdale, M.D., of Lowell and Boston had his license to practice medicine in the State of Massachusetts revoked April 18, 1929, for "gross misconduct in the practice of his profession." There were two hearings in the revocation proceedings—one in January, 1928, at which time Dugdale obtained a writ of mandamus against the state board, and a second one, a little more than a year later, at which time the license was revoked.

Suite 55 Boston, Mass.

Greatly reduced reproductions of some of Dugdale's advertising — letterhead, rheumatism-cure booklet and advertisements, Abrams' "electronic reactions," and his own alleged cancer cure.

The Lowell (Mass.) *Sun*, at the time of the first hearing, published an account of that hearing and stated that the charges against Dugdale grew out of alleged professional misconduct on his part in the treatment of a Mrs. Caton, who subsequently died of cancer. As a result of this publication, Dugdale brought suit against Mr. John H. Harrington, publisher of the *Sun*, charging libel and demanding $50,000 damages. The case came to trial a few weeks ago and lasted about a week. The jury, after less than two hours of deliberation, brought in a verdict in favor of the newspaper.

Frederick Dugdale, according to our records, was born in 1880 and was graduated in 1903 by the Baltimore Medical College. For some years he advertised as a "specialist" in "skin, blood and nervous diseases" and operated a mail-order "rheumatism cure." When the large economic possibilities of the Abrams quackery became obvious, Dugdale was one of the disciples of that cult. In 1921, his name appeared as "President" of the "Allied Medical Associations of America," one of the "twilight-zone" organizations patronized by faddists and quacks. His name also appeared as one of the officers of the "Medical Society of the United States," which was originally created to organize fee-splitters but later became a "society of protest against the autocracy of the A. M. A." Still later Dugdale's name was found as "Chairman" of the "Board of Trustees" of the "American Association for Medico-Physical Research," organized originally by the outstanding quack of the century, Albert Abrams, under the title, "American Association for Spondylotherapy."

Frederick Dugdale is, of course, not a member of his local medical society nor of the American Medical Association. Yet, at the time of the revocation hearings in 1929, he is said to have stated under oath that he was a member of the American Medical Association, and to have produced a membership card from the American Medical Association made out in his name. It seems that due to a clerical error, Dugdale was sent a membership card instead of a receipt for a subscription to THE JOURNAL. As soon as this error was discovered, notice was served on Dugdale, by registered mail, to return the card sent to him in error. To this day the card has not been received by the American Medical Association.

For some years, too, Dugdale had his own "cancer cure," which was vaguely described in an article that appeared under his name in the *Charlotte Medical Journal* in 1918 as a mixture of "specially prepared creosote with a high guaiacol content, scientifically combined with hydro-carbon and essential oils, presenting a mixture which possesses bactericidal and germicidal properties." Still later, as the Koch "cancer cure" became a wonderful money-maker, Dugdale became a Koch disciple and in the recent libel suit the Koch "treatment" figured largely.

The newspaper's defense of the publication of the abstract of the first hearing in the revocation proceedings against Dugdale was that such an abstract was privileged. The newspaper also held that its reference to the case of a Mrs. Caton, who had been treated by Dugdale by the Koch method for treatment, was justified because it was true. It appeared that Mrs. Caton, when in the last stages of cancer, went with her husband and other relatives to Dugdale, who, according to the report, told the members of the woman's family, "I can see no reason why I cannot make her a well woman." He continued to treat the poor woman and received reports regarding her condition up to within two weeks of her death, and until the last appears to have insisted that the poor woman was improving.

The attorney for the Lowell *Sun* introduced a number of reputable physicians as witnesses. Four Detroit physicians, who had investigated the Koch "treatment," went to Lowell to testify: Drs. Frank A. Kelly, James E. Davis, J. T. Watkins and Clarence Owen. In addition, Drs. Timothy J. Leary, Marshall L. Alling, Charles Shanks and George H. Bigelow also appeared for the defense. One of the most important witnesses was Dr. Joseph Colt Bloodgood, who was badgered by Dugdale's attorney in a manner common to such trials. Dr. Bloodgood was asked whether he was known as the "publicity agent for the A. M. A.," whether he was being paid for appearing in the case, whether he received any compensation from the American Medical Association, and whether he expected to get his expenses. Dr. Bloodgood assured the attorney for Dugdale that he did not receive compensation from the American Medical Association, that he was not the publicity agent for the A. M. A., that he would not accept any pay for coming to Lowell to testify, and that there had been no promise even to pay his traveling expenses.

In addition to the purely medical testimony, there was also some interesting testimony from Mr. Austin Lescarboura, former managing editor of the *Scientific American*, on the physical characteristics of the Albert Abrams "mystery box"—the so-called oscilloclast. Mr. Lescarboura was one of several experts who, some years ago, made a thorough examination, from the physical point of view, of Abrams' hocus-pocus. He brought out that the committee of which he was a member made extensive and exhaustive tests to determine the physical phenomena claimed for it. The sum and substance of the findings of this committee were to the effect that there was no basis in fact for any of the Abrams claims in this matter. Mr. Frank Goldman, the attorney for the Lowell *Sun*, in his closing arguments, characterized Dugdale as a quack. Mr. John J. Higgins, Dugdale's attorney, apparently admitted the fact when he retorted that even a quack could be libeled as well as another man.

Not the least interesting feature of the entire case was the complaint on the part of Dugdale's attorneys, as quoted in the published reports of the suit, that Koch, whose alleged cancer cure was administered by Dugdale, "had run out on us" and refused to come to Lowell to testify.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

CARBON MONOXIDE POISONING

To the Editor:—Recently I was called to see a man lying dead in front of his garage. He had been discovered in the garage seated in his automobile, the engine running, and had been dragged out probably dead. The small side door of the garage was about half way open and the main doors were closed, he presumably having gone in to test the engine. There was no reason to suspect suicide and after careful investigation the coroner's physician granted a death certificate giving the cause as carbon monoxide poisoning due to inhalation of exhaust gases from the automobile engine. I had examined this man at fairly regular intervals during the past ten years, for check up on his physical condition, and had never found any organic or even minor disturbances. The last examination was about six months before his death. 1. What are the conditions at necropsy in carbon monoxide poisoning? 2. What changes can be found in the blood of a person dead of this condition; how soon would such blood examination have to be made after death and what are the tests applicable in such a case? 3. Are there any known external evidences of the skin, mucous membrane or the eyes of such a victim, or any known evidence that might clinch a positive diagnosis as to the cause of death from exhaust gas poisoning from an automobile engine? 4. Granted that the small side door of this garage was open at least half way, would gas accumulation be sufficient to be lethal?

M.D., New Jersey.

Answer.—1. After death from carbon monoxide poisoning the surface of the body is usually pinkish or red, which is more pronounced in the dependent parts. The blood is usually fluid, coagulates slowly, and is cherry red. The mucous membranes in the pharynx and stomach may be reddened. There may be small hemorrhages into the pleura, also pulmonary edema with bright red froth exuding from the cut surface of the lung. In typical cases all tissues are redder because of carbon monoxide hemoglobin. There may be, especially after prolonged breathing of carbon monoxide, punctiform hemorrhages and softening in the brain, particularly in the lenticular nucleus. It has been said that after monoxide poisoning from automobile exhaust gas there may be little change in the skin, because it is thought that death may have occurred rapidly.

2. The essential change after death from monoxide poisoning is the presence of carbon monoxide hemoglobin, which may be detectable for some time. The test relied on principally by the United States Bureau of Mines is based on the fact that when normal blood diluted with water is mixed with a solution of tannic and pyrogallic acids a light brown suspension is formed in a few minutes, while blood containing carbon monoxide hemoglobin forms a light carmine suspension. The percentage of saturation of carbon monoxide in the blood can be determined by using a set of standards of different colors corresponding to known amounts of carbon monoxide in combination with hemoglobin. This apparatus, which is simple enough to be used without special training, may be obtained from the Mines Safety Appliance Company, Pittsburgh.

3. This question is covered largely by answers 1 and 2. So far as is known, the actual cause of death from exhaust gases from automobile engines is poisoning by carbon monoxide.

4. While the question cannot be answered definitively on the basis of the information at hand, it is altogether reasonable to conclude that fatal monoxide poisoning might develop under the condition described. It should be borne in mind, however, that no one can tell the internal conditions of a dead body without a proper postmortem examination.

The symptoms and signs of carbon monoxide poisoning in garages do not differ, so far as known, in any essential from the symptoms and signs of carbon monoxide poisoning under other conditions. A recent article bearing directly on the case described by the correspondent is by William D. McNally (Sixty-Three Deaths from Carbon Monoxide Poisoning in Private Garages, *Archives of Pathology* 5:43 [Jan.] 1928). Public Health Bulletin 195, 1930, by R. R. Sayers and Sara J. Davenport, gives a good review of carbon monoxide poisoning; this bulletin can be obtained for 20 cents from the Superintendent of Documents, Government Printing Office, Washington, D. C. A valuable report is that of the Committee on Poisonous Gases of the American Medical Association, "Dangers of Carbon Monoxide Poisoning and Measures to Lessen These Dangers," The Journal, Jan. 18, 1930. (Reprints may be obtained on receipt of 15 cents.)

TREATMENT OF ELONGATION OF COLON

To the Editor:—I have a patient whose descending colon is one and one-half times as long as it should be, the abnormal length forming a loop. Symptoms are of Glenard's disease with constipation and a tendency toward infection of feces in the loop and obstruction. Will you kindly supply me with definite dietary and other aids in treatment. I should also like to know the relative frequency of the condition. The man was told to have the loop removed but I have advised against such a procedure at present. Print inquiry if you wish, but please use initials only.

M.D., Pennsylvania.

Answer.—The condition described is frequent enough to be a rather common occurrence in routine gastro-intestinal roentgen examinations. Unless there are symptoms present, the general opinion seems to be that no treatment is necessary. Certainly surgery should not be instituted, at least until after a thorough and efficient medical regimen. The usual methods of handling visceroptosis are advisable. The patient is generally put at bed rest with the foot of the bed elevated. If, as is usually the case, the patient is undernourished, food is urged to the point of a definite gain in weight. In the beginning, the bowels are handled with enemas of olive oil. After from two to three weeks of bed rest the patient is allowed up, and passive and active exercises are instituted to increase the tone of the abdominal walls. At this time a diet should be arranged to remove the constipation. Different physicians employ different kinds of anticonstipation diets. McLester's "Nutrition and Diet in Health and Disease" may be referred to for further assistance in the diet.

TREATMENT OF PERSISTENT CONJUNCTIVAL INFECTION

To the Editor:—Will you kindly venture a conjectural diagnosis of the following ophthalmic case, which has baffled the physicians of two cities, the patient being now virtually blind as a result: About six weeks ago a man, aged 66, in good health, came to me with what appeared to be rather severe conjunctivitis of the left eye. The usual treatment with silver nitrate, mercurochrome-220 soluble, ethylhydrocupreine, mild silver protein, zinc, milk injections and other remedies failed to halt the disease. Atropine was promptly added and almost daily reports from the laboratory here were that no germ of any description could be found in the secretion. This report has continued to come from every bacteriologic examination, both here and elsewhere (Richmond, Va.). In about ten days the right eye began with similar conjunctivitis with dilated pupil as if secretion from the left eye might have crossed over the bridge of the nose during sleep and infected the right eye. Infection was not thought possible, however, as no germ could be found, and hence the right eye had not been sealed. The inflammation, uncontrolled, gradually involved the intra-ocular structures of both eyes. Corneal ulcerations developed on both eyes, apparently through the constant winking of the lids, which seemed to macerate the epithelium after ten days or two weeks. The conjunctivae were red and thickened now and pus apparently streamed from the eyes. The secretion from both eyes has flowed continuously and seemingly independent of any treatment with antiseptics. As stated, the inflammation has gone on from the outset from bad to worse until now the patient can only tell light from darkness. The pus is still running, with the lower lids greatly thickened and everted as if Nature were now attempting in this belated way to favor drainage of pus away from the cornea of both eyes. The ulcers have become quiescent, having healed to a great extent, but the pupils have ceased to respond to atropine and the patient has reached a helpless state. There is a history of gonorrhea but no active urethritis at present. The patient is a bachelor. Could this be a metastatic infection? We have pulled all his teeth, which were bad. There is no albumin, sugar or other irregularity. The Wassermann reaction is negative. The patient is a railway conductor who has been occupied in the same way every day for forty years. He does not use drugs or handle animals. Must atropine be continued? I ceased atropine about ten days ago. Please reply at once and give what help in the way of suggestions you can.

M.D., Virginia.

Answer.—There are certain forms of conjunctivitis in which none of the well known pathogenic organisms are concerned but seem to be due to a filtrable virus. The most common of these is the so-called inclusion blennorrhea of the new-born. But, in these, corneal ulceration never occurs except as a secondary infection, which is most probable in this case. The likelihood is that the corneal epithelium was macerated by the lakes of pus that were present and through the damaged epithelium there entered into the cornea organisms of a secondary type, most likely staphylococci and streptococci. Atropine should be continued as long as there is still evidence of inflammation. It is probable that foreign protein in shock-producing doses would be of benefit. Frequent irrigations of the conjunctiva with the continued use of silver nitrate are definitely indicated as long as there is a purulent secretion. If the conjunctiva is still so edematous that it protrudes between the lids, ice applications are in order until the edema subsides.

TREATMENT OF PERSISTENT POSITIVE WASSERMANN REACTION IN SYPHILIS

To the Editor:—Will you kindly advise me what to do in the following case: A four plus Wassermann reaction was discovered during a general physical examination. I gave the patient thirty-three neoarsphenamine, three arsphenamine, fifteen sulpharsphenamine, twelve bismuth and fifty-four mercury treatments between Jan. 15, 1928, and July 15, 1930. The Wassermann reactions were 4 plus, 4 plus, 3 plus, 2 plus and 3 plus. He never showed any symptoms referable to syphilis. He has some albumin in his urine, pain over the kidney region and an exfoliative dermatitis over the palms and the soles. This is due to the arsenic. Shall I continue with antisyphilitic treatment? If so, what shall I use?

Harry Hallarman, M.D., New York.

Answer.—At present the patient needs rest, general supportive treatment and possibly intravenous injections of sodium thiosulphate. The urine should be watched carefully. After recovery from the toxic reaction, the spinal fluid should be examined. If this gives positive results, fever therapy with typhoid vaccine or malaria is indicated. If the spinal fluid examination and clinical tests give no indication of central nervous involvement, moderate treatment with bismuth and iodides may be given, with considerable rest intervals. The persistent Wassermann reaction will have to be ignored. Treatment will protect against serious damage from the syphilis.

DEXTROSE AND SALINE SOLUTION BY HYPODERMOCLYSIS

To the Editor:—Is there any reason why dextrose and physiologic solution of sodium chloride should not be given together by hypodermoclysis when indicated? Is there any chemical reaction that would be harmful to the body? Would a 10 per cent solution of dextrose be likely to cause a slough? W. C. Stanberry, M.D., Charleston, Tenn.

Answer.—There is no harmful chemical reaction; but the osmotic tension needs to be adjusted so as not to have it become excessive. When dextrose is added to the saline solution it will, of course, raise the osmotic tension. A 5 per cent solution of dextrose is approximately isotonic with blood serum. Mixing equal quantities of isotonic dextrose solution and of physiologic solution of sodium chloride yields an isotonic solution. Nevertheless, dextrose solution is not as well borne by the subcutaneous tissue as is physiologic solution of sodium chloride; and 10 per cent solution, being hypertonic, may possibly cause sloughing. It is better to give dextrose solution intravenously or intramuscularly rather than subcutaneously.

DERMATITIS FROM SOAP AND CLEANSING WITHOUT IRRITATION

To the Editor:—I have a patient with an eczematoid eruption on the dorsal surface of both hands, extending in between the fingers. The configuration of the eruption suggested a ringworm infection and I thought I found spores on one microscopic examination; but subsequent examinations have not confirmed this finding and it has not responded satisfactorily either to the use of kerolysin (Upjohn) or to ultraviolet irradiation. The patient is a linotype operator. The only possible occupational irritant which I can discover is Lava soap, which she uses freely in cleansing her hands. Perhaps the ink might also be considered. Could you give me any information as to the composition of this soap and whether any of the ingredients would be especially irritating? If so, could you suggest a less irritating cleansing agent? Please omit name if published in The Journal.

M.D., California.

Answer.—There is probably no soap that will not produce a dermatitis in some individual. It is not possible to determine any ingredient in the Lava soap which might be particularly irritating. A good castile soap is usually as little irritating as any.

When the hands are much inflamed they can be cleansed as follows: Rub olive oil into the hands until they are saturated and some excess is left on; then massage into this one or two eggs as necessary to make an emulsion. When this emulsion has been thoroughly rubbed all over the hands, rinse with tepid water and dry. This particular method cleanses the hands thoroughly and leaves a thin film of oil for protection.

DANGER FROM METHANOL AS SKIN RUB

To the Editor:—In the controversy between the producers of denatured ethyl alcohol and the producers of methanol, both the distilled and the synthetic product, in connection with the use of this substance in antifreeze mixtures, the implication has been made that methanol is not absorbed through the skin, or at least no toxic results arise as the result of skin contact, and that methanol might be used as a body rub. I request to be advised as to the facts in the situation. Please omit name.

M.D., Ohio.

Answer.—When methanol is used as a body rub in place of ethyl alcohol, some of the vapor is inhaled. There is some evidence that methanol may be absorbed through the skin. While acute poisoning from the external use of methanol is unlikely, such use is decidedly inadvisable. Methanol is further discussed in an editorial entitled "Another Gas Hazard," in The Journal, August 30.

"IN-NO-SCENT" AND "THE EXPERT"

To the Editor:—1. Kindly advise me regarding a proprietary deodorant known as "In-No-Scent," which a patient has asked me about. 2. I would also like to know about a pamphlet called "The Expert," published by the Riverside Press of St. Paul, giving names of specialists in various lines. Is their publication reliable and do they carry out their contract? Please do not publish my name in The Journal if these questions and answers are published.

K. B. S., M.D., Connecticut.

Answer.—1. We have no information about or record of "In-No-Scent." If it is a product sold for controlling sweat excretion in local areas, such as the axilla, it is likely to contain some salt of aluminum, the basis of most products of this type.

2. We have seen no recent issue of "The Expert." It used to be published by the Imperial Information Bureau of St. Paul and purported to list "Eminent Surgeons, Physicians and Specialists" in various parts of the country. These eminent individuals were classified by groups, such as "Surgeons," "Internists," "Specialists in Nervous and Mental Diseases," "Specialists in Skin and Genito-Urinary Diseases," "Oculists and Aurists," and "Obstetricians." Just what one had to do to qualify as an "expert" for inclusion in the booklet is not quite clear. According to information received, the payment of a fee to the publishers appeared to have some bearing on the matter of eligibility. As long ago as March 27, 1909, The Journal published a protest from a physician in Detroit, who objected to having his name appear in "The Expert." The *Southern Medical Journal* in 1913 contained an editorial in its September issue on the same subject under the title, "Easy Mark Doctors." In June, 1913, the local medical society of Jacksonville, Fla., passed resolutions condemning the publication.

MENINGOVASCULAR SYPHILIS

To the Editor:—I have a young woman patient who developed meningovascular syphilis one year after the initial lesion. After continuous and, at intervals, energetic treatment, the laboratory reports on fluid and serum are negative. However, neurorecurrences persist, and the patient is totally incapacitated a large portion of the time, pain being the dominant factor. If treatment is properly carried forward, how soon may I expect a remission of the more distressing symptoms? Please omit name and address.

M.D., *Texas.*

Answer.—Syphilis is such a chronic disease, its nervous manifestations are so difficult to treat, and its symptoms are so protean that no definite statement can be given as to how soon any given patient might be relieved of any group of symptoms. One can only continue the usual therapeutic measures, treat his patient symptomatically at the same time and hope for the best. The physician must be sure that in a syphilitic patient he is not dealing with symptoms caused by other quite different conditions.

REMOVAL OF WARTS

To the Editor:—Is there any known cause for little elongated warts that occur on the face and body and is there internal treatment for them?

R. F. Sheets, M.D., Carthage, Ill.

Answer.—Ordinary warts sometimes grow long, but the long ones are few among many flat warts. It is assumed, therefore, that the warts referred to are the tiny soft pedunculated fibromas often seen on the neck and about the axillae. The cause is not known, nor is there any internal treatment to benefit them. Clipping them off cures them.

COMING EXAMINATIONS

CALIFORNIA: San Francisco and Los Angeles, Dec. 10, 1930. Reciprocity examinations. Sec., Dr. C. B. Pinkham, 420 State Office Bldg., Sacramento, Calif.

IOWA: Des Moines, Dec. 2-4, 1930. Dir., Mr. H. W. Grefe, Iowa Dept. of Health, Des Moines, Iowa.

KANSAS: Topeka, Dec. 9, 1930. Sec., Dr. A. S. Ross, Sabetha, Kan.

MARYLAND: Regular, Baltimore, Dec. 9-12, 1930. Sec., Dr. H. M. Fitzhugh, 1211 Cathedral St., Baltimore, Md. Homeopathic, Baltimore, Dec. 9, 1930. Sec., Dr. J. S. Garrison, 517 Old Orchard Rd., Ten Hills, Baltimore, Md.

NEBRASKA: Lincoln, Nov. 20-22, 1930. Sec., Mr. Ernest M. Pollard, Lincoln, Neb.

OHIO: Columbus, Dec. 1-4, 1930. Sec., Dr. H. M. Platter, 85 E. Gay St., Columbus, Ohio.

TEXAS: Waco, Nov. 18-20, 1930. Sec., Dr. T. J. Crowe, 918-19 Mercantile Bank Bldg., Dallas, Texas.

UTAH: Salt Lake City, Dec. 15 and 16, 1930. Dir., Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City, Utah.

VIRGINIA: Richmond, Dec. 9-12, 1930. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke, Va.

WEST VIRGINIA: Morgantown, Nov. 20, 1930. Sec., Dr. W. T. Henshaw, Charleston, W. Va.

WISCONSIN: Milwaukee, Dec. 13, 1930. Basic Science. Sec., Prof. R. N. Bauer, 3410 Wisconsin Ave., Milwaukee, Wis.

Michigan June Report

Dr. F. C. Warnshuis, secretary of the Board of Registration in Medicine of Michigan, reports the written examination held at Ann Arbor, June 10-12, 1930, and Detroit, June 16-18, 1930. The examination covered 14 subjects and included 100 questions. An average of 75 per cent was required to pass. Two hundred and seventy-three candidates were examined and passed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
College of Medical Evangelists	(1930)	83.9, 84, 84*

Book Notices

ANATOMY OF THE HUMAN BODY. By Henry Gray, F.R.S. Twenty-second edition thoroughly revised and re-edited by Warren H. Lewis, B.S., M.D., Professor of Physiological Anatomy, Johns Hopkins University, Baltimore, Md. Cloth. Price, $10. Pp. 1391, with 1232 illustrations. Philadelphia: Lea & Febiger, 1930.

William Gray, the author of this textbook of anatomy, died of smallpox at the age of 34. He saw only the first edition of his book, published in 1858, which consisted of 750 pages and contained 363 illustrations. His work was done so well that it has lived through twenty-two editions and still contains many of the original illustrations and much of the original text. The editors have endeavored to adhere to the original plan and have supplied only such changes as advances in science made necessary in order to put at the service of students the latest accessions to anatomic knowledge. Among the great advances made since the first American edition appeared in 1859 have been those in microscopic anatomy and the anatomy of the embryo. New material on these subjects has come to occupy a considerable portion of the text, although the main portion has always remained primarily a descriptive anatomy of the human body. In this edition the section on the central nervous system has been revised. New material has been added on the physiologic anatomy of various organs. New illustrations have been added and many old ones have been replaced. The nomenclature, as in previous editions, has remained in English, and important references to the literature have been added at the end of each section. The publishers have done well to provide a volume used so much by students that will remain open and flat at almost any page.

AN INTRODUCTION TO THE STUDY OF HUMAN ANATOMY. By Robert James Terry, A.B., M.D., Professor of Anatomy in Washington University. Cloth. Price, $3.50. Pp. 346. New York: Macmillan Company, 1929.

Dr. Terry is professor of anatomy at the Washington University School of Medicine, St. Louis, and associate editor of the *American Journal of Physical Anthropology*. This volume is a student's guide in the dissecting room. The laboratory method is emphasized, with many new methods of procedure and demonstration. Descriptive text is omitted. The author recommends two modes of inquiry in the study of gross structure of the human body. The student follows the direction in his laboratory study of the cadaver as a source of his knowledge, and the evidence of demonstration is to be verified by the description given in a good textbook on anatomy. The process of inquiry in learning human structure by the laboratory method is augmented by direct individual investigation. Problems are assigned in rotation to students and the observations made are recorded on special form sheets. The directions for laboratory work cover five sections, each of which represents a part of the body commonly designated in the assignments of a dissecting room. Collateral reading is stressed by the author as an important part of training and he has appended reading references for each anatomic unit assigned for study. At the close of each chapter are found recommendations for study which is to be carried on outside the laboratory—in the library, at the dispensary, in the pathologic museum and especially in the necropsy room. The Basle Anatomic Nomenclature in both Latin and English is consistently used. The author's aim is to develop in the student a sense of investigation which will make him an independent worker. The book will be found valuable to teachers not alone because of the succinct directions given for successive steps in the section but also because of the new pedagogic angle of approach to study. By faithfully following this method of teaching the student will not lose interest in the accurate investigation of facts. He will gain the proper perspective by orientating this anatomic knowledge in a relation to the various departments of biology, medical science and other subjects correlated with anatomy. The two procedures, verification and original observation, provide the main foundation of the student's knowledge of an anatomic method and subject method such as has been well worked out in this introduction to the study of human anatomy.

Plarr's Lives of the Fellows of the Royal College of Surgeons of England. Revised by Sir D'Arcy Power, K.B.E., F.R.C.S., Hon. Librarian Royal College of Surgeons, with the Assistance of W. G. Spencer, O.B.E., M.S., F.R.C.S., and Professor G. E. Gask, C.M.G., D.S.O., F.R.C.S. Volume I and Volume II. Cloth. Price, 42/— net. Pp. 752 and pp. 596. London: John Wright & Sons, Ltd., 1930.

This volume is unusual among biographies. Here are the records of the surgeons of the old school who carried on during that brilliant period of English operative surgery instituted by Lister. The actual achievement of this publication is accredited to Lord Moynihan, who acted on the suggestion of Sir John Bland-Sutton. It was realized in printed form through the gift of £5,000 by the late Mr. Thelwal Thomas, to whom the volumes are a memorial. The dedication is rightfully given to Mr. Victor Plarr, librarian of the college whose obituary records form the basis of the work. Following a memoir of Plarr is a transcript of the charter of the Royal College of Surgeons and a list of the 300 surgeons elected as fellows in 1843. Credit must be given the editor, Sir D'Arcy Power, and his collaborators, Walter Spencer and Prof. G. E. Gask, for their painstaking compilations.

The work includes the biographies of 2,600 members elected since the establishment of the college in 1843. Supplementary editions will be issued at ten year periods. The records of members from 1745 to 1843 are yet to be done. The two volumes give complete information of that "great majority, more ambitious than their fellow students, who took the qualifications in surgery, and who used their talent, not only professionally, but often performed public duties, as well as those whose memorial consists of no more than a brief obituary notice." When possible the individual's professional history is completed with pen pictures of his appearance, traits of character and idiosyncrasies. Mention is made of the activities of fellows outside their profession; many were men of varied attainments who brought their zeal to bear on sciences other than surgery, and many were noted as appreciative of the beauties of nature and lovers of the arts.

The biographies are replete with the testimonials of friends, honors received, hospital and university connections and lists of their publications, and the whole is freely spiced with anecdote. There pass in review such surgical pathologists as Edward Stanley, William Lawrence, Sir James Paget and Sir William Savory; men who devised brilliant departures in surgical procedure as Arthur E. J. Barker, who established the early diagnosis and operation for intussusception and who pioneered, as did Francis Woodhouse Braine, in placing local anesthesia on a firm scientific basis. There were men such as Forbes Frazer, who worked in the cause of medical union, and Sir John Simon, the maker of modern sanitary science in England. There was the great war surgeon Sir Anthony Bowlby, and John Wyley of the Indian Service. Such daring experimentalists as James Edward Adams, who transfused his own blood into the veins of a patient in collapse, Sir Victor Alexander Horsley, who made fifty hazardous self-demonstrations of anesthesia and who contributed so much to knowledge of the pathology of the nervous system, and James Syme, the boldest and most original surgeon of the era preceding the introduction of anesthesia are made to live again. Adequate space is given the men who devised technics of historic importance. Among others were Sir Benjamin C. Brodie, who popularized the method of lithotrity in England; Charles A. Key, who was the first to ligate successfully the subclavian artery for the cure of axillary aneurysm; Odilon Marc Lannelongue, the first surgeon in France to open the skull for the relief of the compression of the brain; Macewen, who invented the operation of linear osteotomy, and Lawson Tait for his procedures in abdominal surgery. The lengthy biography of Sir Frederic Treves embraces an epitome of the history of surgery of intestinal obstruction and appendicitis. Readers cannot but be inspired by the lives of men who advanced systematic scientific research such as Joseph Blake, who migrated to America and at St. Louis was among the first to introduce animal experimentation in the western country; Sir William Bowman, "the father of general anatomy in England," and Theodor Kocher, who was the first advocate of Lister's methods in Switzerland. The detached references to education in the Victorian, Edwardian and early Fifth Georgian eras would be incomplete without credit to such teachers as Sir George Murray Humphry, who converted the insignificant medical school at the University of Cambridge of 1866 into one that is world renowned; Thomas Huxley, who was one of the founders of the school from which biology came as a science; and Thomas Wharton Jones, the distinguished ophthalmologist "whose work marks, with Waller, the beginning of modern scientific physiology in England." Prominent figures in English medical history were also Sir Jonathan Hutchinson, a medical genius superior in his knowledge of the history of medicine, and Sir James Paget, who linked the surgery of John Hunter with that of the present day. Joseph Lister was elected a fellow of the Royal College of Surgeons in 1860 and delivered the Croonian lecture in 1863, taking as his subject "The Coagulation of the Blood." In 1869, he published his "The Antiseptic Method of Treating Compound Fractures and the Use of Catgut Rendered Aseptic by Carbolic Acid Ligatures." More than ten pages are devoted to the epochal experiments of Lister, who "revolutionized the art of surgery and started an indefinite extension by inventing the first method through which a surgeon was able with certainty to prevent inflammation from disturbing nature's healing of a wound." Here is the whole story of Lister's fight to obtain a hearing in the face of the prejudices of his senior surgeons.

Intimate knowledge is given of the personalities of men who have contributed definitely to the scientific advancement of the world. The publication will doubtless find a welcome response from readers who are interested in the progress of surgery from the introduction of anesthesia and antiseptics to the asepsis of today.

Discoveries and Inventions of the Twentieth Century. By Edward Cressy. Third edition. Cloth. Price, $4.25. Pp. 476, with 342 illustrations. New York: E. P. Dutton & Company, 1930.

Subsequent to the publication of the first edition of this book in 1914 the World War stimulated research and discovery in many directions. Moreover, the volume has become a classic work of reference. This edition covers such new subjects as artificial silk, television and phototelegraphy. The chapters of special interest to physicians are those on electricity, artificial production of cold, chemistry and radium. The illustrations are well printed and the index is good.

Le diabète sucré son traitement. Par P. A. Carrié, médecin des Hôpitaux de Paris. La pratique médicale illustrée. Directeurs Professeur E. Sergent, R. Mignot et R. Turpin. Paper. Price, 20 francs. Pp. 94. Paris: G. Doin & Cie, 1930.

It is a general fault of articles in the French literature that practically no attention is paid to the matter of bibliography. Carrié's treatise is no exception, and this detracts considerably from the value of the book to those who may wish to go to original sources for confirmation of the statements made in the text. Such neglect of the literature gives the impression that the authority of the professor's spoken word is supreme in France and that the critical questioning of authority, which has developed particularly in Germany and America and is so stimulating to progress, is sadly lacking there. A few errors are noted. The author, for instance, in a footnote infers that alcohol is converted into sugar. He also contrasts the ketogenic antiketogenic ratio 2/1 of Shaffer with the 4/1 ratio of Ladd and Palmer, overlooking the fact that Shaffer's ratio is one of molecules of fatty acid to molecules of dextrose, whereas Ladd and Palmer are expressing the proportions in terms of grams of fat to grams of carbohydrate. Recalculated into molecules, Ladd and Palmer's ratio is essentially the same as that of Shaffer. It is also evident from the context that the author has not comprehended the fact that these ratios are significant only as they express the proportions of the various food factors actually metabolizing. The ratio of the factors in the diet will only be the same as that of foods metabolizing when none of the food eaten is stored and all caloric requirements are perfectly satisfied. The treatment of coma, from the point of view of many American clinicians is inadequate. The use of alkali is reserved for cases when insulin is temporarily unobtainable and little or no attention is paid to the important question of providing fluids to combat dehydration. The consideration given the question of diabetes in pregnancy is not satisfactory. Increasing severity as pregnancy progresses is not a common observation; on the contrary, in many instances the tolerance increases in the later months of pregnancy and continues high during lactation. Nor can one agree with the unqualified statement that nursing the infant aggravates the mother's diabetes. Despite these few objections the treatise is an excellent presentation of a method of treating diabetes, which resembles closely that in use in the leading American clinics, a method in which empiricism has been replaced by a scientifically adjusted dietary and the precise use of the now available substitution therapy.

Ephedrine and Related Substances. By K. K. Chen, Department of Pharmacology, Johns Hopkins University, and Carl F. Schmidt, Department of Pharmacology, University of Pennsylvania. Medicine Monographs, Volume XVII. Cloth. Price, $2.50. Pp. 121. Baltimore: Williams & Wilkins Company, 1930.

This volume is a medical monograph that deals with the subjects indicated in the title. It therefore is a digest of the literature rather than a record of the authors' researches. The text is up to date, is well written, and should be of value to those interested in the subject. It is particularly fitting that the authors are the discoverers of the physiologic action that has raised ephedrine from obscurity to its place of importance in medicine. An excellent bibliography adds to the value of the volume.

The Cancer Process. By J. J. M. Shaw, M.A., M.D., F.R.C.S.E. Paper. Price, 1/— net. Pp. 16. Edinburgh: E. & S. Livingstone, 1930.

From available publications by deduction the author arrives at the conclusion that cancer is produced by the prolonged contact of living tissue and any substance that is viscous, insoluble in tissue fluids, and toxic. The hyperplasia induced is of a protective nature. These substances imitate in their action the fibrinous exudate that is responsible for the multiplication of cells in repair and after conception, the intermediate mechanism being an affinity of potassium for vitiated cytoplasm and a resulting imbibition of fluid. Because of the ability of potassium in cells to change gamma rays to beta rays, he is led to the view that intensification of gamma rays outside the body will develop increased secondary beta radiation, which will inhibit and destroy the proliferating cells. It now remains to produce evidence that this conception gets somewhere practically.

Edward Jenner and the Discovery of Smallpox Vaccination. By Louis H. Roddis, Lieutenant Commander, Medical Corps, United States Navy. Cloth. Price, $1. Pp. 155, with illustrations. Menasha, Wisconsin: George Banta Publishing Company, 1930.

This essay is a most satisfactory sketch of Edward Jenner. A consideration of smallpox inoculation is introduced at the beginning of the book and discussed in its historical bearings. Of especial interest to Americans is a reprinting in Chapter III of "Some Account of the Success of Inoculation for the Smallpox in England and America," published in London in 1859 by Benjamin Franklin. This includes "Plain Instructions for Inoculation in the Small-Pox," prepared by William Heberden. The author writes in an interesting manner of Jenner's early years and education, of his long years of arduous labor as a country practitioner, of his observations in natural history under the inspiration of John Hunter, and of his efforts to write poetry. The story of vaccination from the first observations in Gloucestershire until the practice had spread over the world is related in a connected manner. The introduction of a few pictures and numerous letters gives a strong personal tone and add much to the interest of the story. An excellent bibliography, a chronology of the principal events of Jenner's life, and a list of Jenner's published works close the essay. Some interesting statistics bearing on vaccination are included in the appendix. It is fortunate to have a readable life of Edward Jenner built on extensive research and study of original materials from which the author has judiciously selected such portions as are vital and instructive. The appearance and excellence of this volume remind one of other short biographies, such as Osler's "Thomas Linacre" and Riesman's "Thomas Sydenham," and like them it will furnish a pleasant and profitable hour to those who read it.

Thérapeutique médicale. I. Maladies du tube digestif. Par Maurice Lœper, professeur de thérapeutique à la Faculté de médecine de Paris. Avec la collaboration du Dr. André Lemaire, chef de laboratoire à la Faculté. Paper. Price, 50 francs. Pp. 369, with 45 illustrations. Paris: Masson & Cie, 1930.

"The world of man," says Loeper, "is divided into two classes: those who believe in therapeutics and those who mock it." Inferentially, this book is intended to lessen the number in the latter class. It is the first volume of a series planned by the author to cover successively the therapy of the various other organs and systems. This volume deals with the therapeutics of the various functional subdivisions of the alimentary tract, especially from the standpoint of the remedies employed. The author's studies lead him to believe that bitters not only have a reflex effect in increasing gastric secretion by excitation of the sense of taste but also have a direct effect on the stomach, when introduced into it by means of a tube. They also produce transient leukocytosis, which is especially marked with quassia and columba. The author believes in pepsin, not only as substitution opotherapy but also as an excitant of gastric secretion and as a "regulator of the digestive hormones." He has shown it to be a stimulant to colonic motility, on hypodermic injection. As yet unappreciated therapeutic possibilities may reside in the injection of pepsin. He believes in the efficiency of orally administered pancreatin, especially with enteric coating; also that enteric pills of 0.20 Gm. of magnesium sulphate might be capable of exciting contractions of the gallbladder; and he does not express the reasonable doubt that the enteric coating may not dissolve at exactly the point it is intended to. All of this is mentioned to illustrate the rather optimistic tendency of the author, who evidently belongs to the first of the two classes mentioned. One naturally wonders whether the therapeutic optimism of the teacher might not be responsible for therapeutic nihilism developing among some of the disappointed students. There is, nevertheless, a great deal of good in this volume, the careful perusal of which certainly inculcates therapeutic resourcefulness.

Grow Thin on Good Food. By Luella E. Axtell, M.D. Cloth. Price, $2. Pp. 336, with illustrations. New York: Funk & Wagnalls Company, 1930.

Here is a popular guide in simple language for the overweight person who wishes and needs to reduce to normal. It is based on experience from the author's own reduction and from treatment of many obese patients. Tricks in cookery, cooking hints, are given to show how calories can be "squeezed" out of delightful dishes. Many menus and recipes are proposed for reducing body fat only and for yielding all nutrient needs. Exercise and work cooperate with the diet in the reduction program. Courses of exercises are outlined. Heat and cold treatments used with care are accessories to diet restrictions. When reduction has been accomplished, weight should be maintained at normal with the vital foods providing sufficient minerals, proteins and vitamins to meet all body needs.

Traitement médical des affections stomacales. Par Léon Meunier. Paper. Price, 22 francs. Pp. 211, with 34 illustrations. Paris: Masson & Cie, 1930.

This booklet, the result of thirty years of gastro-enterologic practice and experimental researches, is more important as a contribution to the literature on the subject than its size would suggest. It develops certain points of view that have not yet found general acceptance and deserve a hearing. Thus, the author's researches, in agreement with other French observers, point to a certain molecular concentration as a determining factor in gastric evacuation. Saline as well as nutritive solutions are retained in the stomach until the cryoscopic index is in the vicinity of 0.38; such is represented, for example, by 0.55 per cent solution of sodium chloride, a 1 per cent solution of sodium bicarbonate, of dried sodium sulphate, or of dried sodium phosphate and a 2 per cent solution of dried sodium citrate. This is why mineral waters of the proper freezing point, such as vichy water, are better tolerated by the stomach than are others. Medicinal solutions prescribed for digestive disturbances should be at this ideal freezing point. All delayed epigastric pain or distress relieved by food or alkali is, in the author's opinion, due to pylorospasm produced by disproportion between the acidity of the gastric juice and the alkalinity of the duodenal juices: in other words, insufficient neutralization in the duodenal bulb. Even though there is excessive gastric acidity, pain does not occur as long as the duodenal secretions are capable of compensating; and, on the other hand, though gastric acidity is normal, a deficiency in duodenal alkalinity will produce the pain. The author studied duodenal hypo-alkalinity by a combined duodenal and gastric test meal after double intubation. He is inclined to ascribe the condition to high acidity of pathologic bile and finds it generally associated with hypercholesteremia. Alvarez's ingenious suggestion that pylorospasm is one of the phenomena of reverse peristalsis is not mentioned by the author, although, since as duodenal juice regurgitation occurs normally and is capable of cutting down excessive gastric acidity, it is probable that pylorospasm is the primary factor and the cause of disproportion in the hydrogen ion concentration at the pylorus, which then tends to be maintained as a vicious circle. The booklet concludes with cooking recipes for patients with gastric hyperacidity, duodenal hypo-alkalinity and gastric hypo-acidity. Even though some of the author's therapy may be rather visionary at times, as his recommendation of enteric capsules of sodium bicarbonate for duodenal hypo-alkalinity, the place in the intestine where such capsules may open being entirely problematic, one cannot but help wishing, in view of the many good things contained in it, that it may secure translation into English.

A Manual of Normal Physical Signs. By Wyndham B. Blanton, B.A., M.A., M.D., Assistant Professor in Medicine, Medical College of Virginia. Second edition. Cloth. Price, $3. Pp. 246, with 49 illustrations. St. Louis: C. V. Mosby Company, 1930.

This small volume contains much information in tabular form and many diagrams of the location of organs with relation to the surface of the body. The material comprises only the normal physical signs. Under the lymphatic system, for example, there are tables showing what part of the head each group of glands drains. The parotid nodes drain the scalp, the middle ear and the chin. The axillary nodes drain the arm, the chest wall, the abdominal wall and the hand and breast. There are similar tables showing what lymph nodes drain other areas of the body. Under the subject of blood pressure there are brief tabulated definitions of fundamental terms such as pulse pressure, mean tension, hypotension, systolic blood pressure and diastolic blood pressure. The technic of taking blood pressure and the factors that cause it to vary are listed and so on through all parts of a physical examination. The aim was to list the normal signs so that they may be found promptly without having to read a long time, and that is the chief advantage in this style of book.

Nahrungsmittel-Tabelle zur Aufstellung und Berechnung von Diätverordnungen für Krankenhaus, Sanatorium und Praxis. Von Dr. Hermann Schall, Leitender Arzt des Kindersanatoriums, Königsfeld. Ninth edition. Paper. Price, 5.40 marks. Pp. 124. Leipzig: Curt Kabitzsch, 1929.

This is simply a complete collection of tables of food values organized according to the various classifications of foods, and according to the various types of values with which the dietitian is concerned. It is as complete and scientific a series of tables of this character as is available.

Seventy Birth Control Clinics. A Survey and Analysis Including the General Effects of Control on Size and Quality of Population. By Caroline Hadley Robinson. Foreword by Robert Latou Dickinson. Cloth. Price, $4. Pp. 351. Baltimore: Williams & Wilkins Company, 1930.

The physician will be amply repaid, whatever attitude he takes on the subject of birth control, if he will carefully consider the contents of Mrs. Robinson's book. Written by a student of economics and not a biased reformer, the book presents facts rather than extravagant speculation. The fact that the manuscript is the first of a series of publications on the medical aspects of human fertility, issued by the National Committee on Maternal Health, is an added recommendation. In the foreword, Dickinson says: "Every new endeavor to better public health passes through a difficult early stage. . . . Control of conception presents no exception." Mrs. Robinson says: "We are coming to realize that voluntary limitation of the family is an essential part of the economic structure of nearly every age and clime, and that we must choose between measures . . . in particular the old forms of limitation by abortion and infanticide, by celibacy or postponement of marriage (with prostitution) and the newer discoveries of social medicine." A complete survey of the seventy birth control clinics is taken up the first part of the book, and social implications of birth control in the second. A full bibliography and adequate index are found at the end.

Life Insurance: Cancer and Good Health

(Vann v. National Life & Accident Ins. Co. (Texas), 24 S. W. (2d) 347)

On March 28, 1926, Carrie S. Vann entered a sanatorium for treatment for a cancer of the cervix of the uterus. She was given a radium treatment and several roentgen treatments. On or about April 5, she was discharged. On May 17, the National Life and Accident Insurance Company issued a policy on her life. Mrs. Vann was taken to the hospital every two weeks for examination, but she was given no treatment. According to the testimony of her physician, after she left the hospital there was a period during which he could find no trace of the cancer, and the patient had no symptoms of it. She resumed her ordinary household duties and gained back her ordinary weight and strength. In September, however, there was a recurrence of the cancer, and the patient died, Feb 10, 1926 [sic]. When she died, the insurance company resisted payment, alleging that the insured was suffering from cancer when she applied for insurance and that her statements with reference to being in good health were untrue and false and were made for the fraudulent purpose of inducing the company to issue a policy on her life. The beneficiary under the policy, the husband of the insured, brought suit. The case was tried before a jury, which, at the conclusion of the testimony, was instructed by the court as follows:

> To aid you in answering the following question, the Court instructs you that sound health, as that term is used in this charge, does not mean perfect health; it does not mean absolute perfection, but sound health in the construction of life insurance policies is a state of health free from any disease or ailment that affects the general soundness and healthfulness of the system seriously, that is, that the insured be not afflicted with a disease or bodily infirmity of a substantial nature, which affects the insured's general health, or which materially increases the risk to be assumed by the insurer.
>
> 1. Was Mrs. Carrie S. Vann, wife of the plaintiff, in sound health as that term has been hereinabove defined to you, at the time the policy in question was issued on the 17th day of May, 1926? Answer yes or no.

Under the foregoing instruction, the jury found that the insured was in good health when the policy was issued, and judgment was issued against the insurer. The insurer appealed to the Court of Civil Appeals for the Eighth Supreme Judicial District, which reversed the judgment of the court below and rendered judgment in favor of the insurer. Thereupon the beneficiary under the policy appealed to the Commission of Appeals of Texas, Section A.

We think, said the Commission of Appeals, that there was sufficient evidence to raise the question as to whether or not the insured was in sound health, as the term was defined by the court, at the time the policy in question was issued, May 17, 1926. The Court of Civil Appeals erred in reversing the case and rendering judgment in favor of the insurer The rule of law in Texas is that the Court of Civil Appeals may reverse the judgment of a trial court on the preponderance of evidence, but it cannot render the judgment, if, disregarding all adverse evidence and giving credit to all evidence favorable to the plaintiff, and indulging every legitimate conclusion favorable to the plaintiff which might have been drawn from the facts proved, the jury might have found in favor of the plaintiff.

Winninger v. *Ft. W. & D. Ry. Co.* 105 Texas 56, 143 S. W. 1150. For the reasons stated above, and for other reasons stated in the opinion, the judgment of the Court of Civil Appeals was reversed, and the judgment of the trial court in favor of the beneficiary under the insurance policy was affirmed.

Hospital Liable for Fatal Tonsillectomy

(Gilstrap v. Osteopathic Sanatorium Co. (Mo.), 24 S. W. (2d) 249)

The Osteopathic Sanatorium Company operated the "Still-Hildreth Sanatorium," Macon, Mo., for the treatment of mental and bodily diseases according to osteopathic methods. On the staff was one R. J. McReynolds, an osteopath, whom the company paid a salary and provided with room and board. McReynolds, however, "Specializing in Eye, Ear, Nose and Throat," was associated with two osteopaths in Macon, who were authorized to make appointments for him.

Raymie Gilstrap called at the sanatorium with a friend, Sept. 6, 1928. He introduced McReynolds, saying, "This is the doctor that is going to remove my tonsils." Gilstrap returned to the sanatorium about half-past two on the afternoon of September 8. After some delay, McReynolds undertook to remove his tonsils under local anesthesia but was unable to do so. After McReynolds gave up the operation under local anesthesia, Gilstrap lay down about fifteen minutes. Then McReynolds took him in a car to the hospital connected with the Kirksville College of Osteopathy and Surgery, about 32 miles away. There Gilstrap was given a general anesthetic. He was removed to the operating room about 6:20, but McReynolds did not begin the operation until about 7 o'clock. About forty-five minutes later, a surgeon, Petermyer, connected with the hospital, came into the operating room and called McReynolds' attention to the weak and rapid pulse of his patient. The tonsils had been removed, but there was a "constant welling up of blood." McReynolds, who had been trying to stop it with a sponge, asked Petermyer's advice. Petermyer advised suturing, but McReynolds said that he had never done that and did not care to do it. Petermyer sutured, at McReynold's request, and the hemorrhage stopped. About 8 o'clock the patient was removed to his room, cyanotic, gasping for air, and without a discoverable pulse at the wrist. A glucose solution was injected and adrenalin was administered, but shortly after 9 o'clock the patient died.

Gilstrap's widow brought suit against the Osteopathic Sanatorium Company and obtained a verdict for $6,500. The sanatorium company appealed to the Kansas City Court of Appeals. It asserted, among other things, that there was no evidence on which to submit to the jury the question of the defendant's liability for McReynolds' acts and claimed that he was not the agent of the company but acted on his own behalf. Hildreth, the president and superintendent of the sanatorium, testified that the sanatorium was conducted solely for the treatment of nervous and mental diseases, that surgery was not employed, and that surgical cases were not admitted. There was no evidence, however, that Gilstrap knew that the company claimed that it treated only nervous and mental diseases, and the company was not entitled to any inference that he had any such knowledge. It was proper to assume only that Gilstrap believed that he was entering the sanatorium as its patient, to be treated by its physicians and surgeons. When he entered the sanatorium, the relation of physician and patient was created between him and the company. The relation continued until changed by mutual consent, or until reasonable notice was given, or until ended by his dismissal. The fact that the operation was ended elsewhere than at the sanatorium was of no consequence, if the relation of patient and physician existed and continued to exist throughout his treatment.

The claim of the Osteopathic Sanatorium Company that there was no proof of negligence on McReynolds' part and no proof of malpractice for which the company was responsible was met by the following statement by the court:

> Sufficient proof was made. The operation upon the patient was continued an unreasonable length of time, four times as long as would reasonably be required; dangerous hemorrhage was produced during the operation; the doctor in charge either failed to discover it or failed to stop the hemorrhage; and when advised by another doctor, about 45 minutes after the beginning of the operation, that the wound should be sutured in order to stop the hemorrhage, he declined to do it himself, but requested the other doctor to do it; that [sic] at the time the wound was sutured it was too late to save the patient's life on account of the loss of blood, and the unreasonable length of time of the operation. These, with other facts and circumstances in evidence, show that the treatment and operation upon the patient was not only improper and ill-advised, but was a complete and tragic bungle from its inception to its end. This presents a patent case of a doctor subjecting a patient to improper treatment, and allowing the patient to bleed to death, when in the exercise of ordinary skill it could have been prevented.

The Osteopathic Sanatorium Company asserted further, in support of its appeal, that no causal connection had been established between the alleged negligence and the death of the patient. But, said the court, there was nothing from which the jury could reasonably have concluded that death was due to any cause other than negligence and improper treatment, and no expert testimony on this subject was necessary. The company had not attempted to justify or excuse the methods adopted or to show that carelessness in the operation was not the cause of death or that death could not have been prevented by the use of ordinary skill. The court continued:

> For the jury to find, or for us to hold that defendant, as the doctor of this patient, did use reasonable care and skill, would be to profane the noble and humane profession of the healing art. Defendant employed and harbored an incompetent doctor in its sanatorium, and held him out to the public as safe and fit for all functions apparently intrusted to him, and should not be permitted to escape the consequences of his incapacity. If it could escape on the mere assertion that the doctor was not its agent, which assertion the jury did not believe, then the defendant, without responsibility, could entrap the innocent and unwary.

For the reasons here stated and for other reasons stated in the opinion, the judgment of the court below, in favor of the widow of the deceased was affirmed.

Illness of Juror: Effect on Verdict.—The separation of a sick juror from other members of the jury, in charge of a deputy sheriff, for medical attention, by direction of the court, pending the trial and after the jury had been ordered to be kept together, was a proper exercise of the court's discretion and could not be regarded as a violation of the order requiring the jury to be kept together, nor as imposing on the state the burden of making an affirmative showing that the sick juror was not exposed to any improper influence. The physician summoned by direction of the judge administered to the juror about 7 o'clock in the morning a hypodermic injection containing one-fourth grain of morphine and left with him a preparation of bismuth and paregoric. He stated that when the juror went back to service in the afternoon he was suffering no pain and his mental condition was normal. Although the sick juror sat in a rocking chair, supported by pillows to make his position more comfortable, during the remainder of the trial, there was no showing made that the juror was incompetent No objection was made by the appellant, as should have been done if the juror's condition warranted it, to proceeding with the trial, because of the juror's condition, but an attempt was made to explain this by stating that until after the trial was completed attorneys for the appellant had no knowledge of the kind of medicine that had been administered The court had held, however, in previous cases, that no error was committed in denying motions for a new trial on the ground that a juror had the appearance of being asleep or was asleep during the progress of the trial. *Pelham* v. *Page*, 6 Ark. 535; *Dolan* v. *State*, 40 Ark. 454. In the present case, the court found no error in the record. The judgment following conviction of second degree murder was affirmed, one justice dissenting.—*Spence v. State (Ark.), 24 S. W. (2d) 331.*

Society Proceedings

COMING MEETINGS

American Society of Tropical Medicine, Cleveland, December 27-30. Dr. Edwin Peterson, U. S. Naval Hospital, Washington, D. C., Secretary.
American Student Health Association, New York City, December 29-30. Dr. D. F. Smiley, Cornell University, Ithaca, N. Y., Secretary.
Radiological Society of North America, Los Angeles, December 1-5. Dr. I. S. Trostler, 25 East Washington Street, Chicago, Secretary.
Society of American Bacteriologists, Boston, December 29-31. Dr. James M. Sherman, Cornell University, Ithaca, New York, Secretary.
Southern Surgical Association, Lexington, Ky., December 9-12. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.
Western Surgical Association, Kansas City, Mo., December 5-6. Dr. Frank R. Teachenor, 306 E. Twelfth St., Kansas City, Mo., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

180: 453-596 (Oct.) 1930

*Clinical and Pathologic Studies on So-Called Tubular Nephritis (Nephrosis). S. B. Wolbach and K. D. Blackfan, Boston.—p. 453.

*Transfusion of Blood in Bright's Disease. H. O. Mosenthal and B. Ashe, New York.—p. 476.

*Etiology of Erythema Nodosum in Children: Relation to Early Tuberculous Infection. L. B. Dickey, San Francisco.—p. 489.

*Antistreptococcus Serum Treatment of Patients with Rheumatic Fever. C. H. Hitchcock, C. McEwen and H. F. Swift, New York.—p. 497.

*Blood Transfusion in Acute Infectious Diseases. J. F. Landon, New York.—p. 514.

*Venous Murmurs Found in Hepatic Cirrhosis and Confusion with Murmurs of Congenital Heart Disease. N. B. Gwyn, Toronto.—p. 525.

*Chronic Cholecystitis: Motor Disturbances of Gastro-Intestinal Tract in Relation to Preoperative and Postoperative Symptoms. N. W. Jones and D. L. Palmer, Portland, Ore.—p. 531.

Visceroptosis. B. P. Seward, Roanoke, Va.—p. 548.

*Visceral Pain. R. D. Rudolf and A. G. Smith, Toronto, Canada.—p. 558.

So-Called Tubular Nephritis (Nephrosis.)—Wolbach and Blackfan report eight fatal cases of acute tubular nephritis in children, with a view of ascertaining the accuracy with which a pathologic diagnosis can be determined from a consideration of the clinical and laboratory data. They believe that these cases are representative of a disease entity in childhood. This belief implies a common etiology or pathogenesis for the series. The pathology of the kidneys affords no premises for the explanation of the important physiologic disturbances of the disease and, therefore, they do not believe that the primary effect of the etiologic agent is on the kidneys or that the important manifestations of the disease are consequences of injury specific to the kidneys. The histologically demonstrable damage to the kidneys was found in the tubules. The glomeruli showed only lesions accountable for either by the terminal infection or severe degeneration of the tubules of the same units. In general the glomeruli were without lesions. Conclusion regarding the rôle of the thyroid in this disease is not possible. The thyroid lesion is probably a manifestation of functional exhaustion and, therefore, probably is neither cause nor direct consequence of the kidney damage. The pathology of the liver, and slight atrophy and degeneration of the hepatic cells, may also be interpreted as effects of overtaxed functional activity consequent to the loss of blood proteins. While offering no substitute, they believe that any name implying a renal origin, such as nephrosis or tubular nephritis, is not appropriate to this disease.

Transfusion of Blood in Bright's Disease.—In cases of Bright's disease treated by other clinics or physicians, Mosenthal and Ashe have noted that transfusions of blood have been resorted to without untoward results; however, many clinicians fear the use of blood transfusions in nephritic patients because of damage that might be induced in the kidneys. This fear seems not to be the result of actual experience but to be based merely on certain preconceived impressions. From their own observations and those in the literature, they believe that anuria and other complications of transfusion are rare and, furthermore, are not more common in cases of Bright's disease than in other conditions. Several instances of nephritis and anuria are quoted, in which transfusions were followed by distinct improvement in the activity of the kidneys; in their experience, transfusions of blood have no distinct diuretic effect and they believe that when an increased output of urine resulted it was due to the recovery of the kidney function independently of the added blood. Transfusions of blood in Bright's disease do not raise the blood pressure, do not injure the kidneys, and neither relieve nor aggravate uremic symptoms; they furnish the most suitable means of treating the secondary anemia accompanying marked renal insufficiency; in one case of anasarca complicating a chronic diffuse nephritis, neither the subcutaneous edema nor the ascites was relieved by raising the hemoglobin and red blood cells to normal levels by means of repeated transfusions. The principal indication for the transfusions of blood in Bright's disease is in the relief of the progressive secondary anemia accompanying impairment of renal function. In such cases it is impossible to remedy the condition by a high-protein diet, as retention uremia would be a sequel. Transfusions will ameliorate a serious condition for a long period when the kidneys are moderately involved, for a short time only if the renal parenchyma is largely destroyed. Several successive transfusions are, as a rule, necessary to restore the hemoglobin and red blood cells to an approximately normal level. The procedure may have to be repeated at intervals if the secondary anemia recurs.

Etiology of Erythema Nodosum in Children.—Eight cases are reported by Dickey. He says that erythema nodosum may occur in nontuberculous individuals or in those infected with the tubercle bacillus. The great majority of cases of erythema nodosum in children are associated with a tuberculous infection and most of the infections are initial and recent. Most children who have erythema nodosum exhibit marked hypersensitiveness to tuberculin given intracutaneously. There may be associated, in addition to the tuberculous infection, other conditions which possibly influence the hypersensitiveness to tuberculin. In many cases of erythema nodosum in children, epituberculous lesions in the pulmonary parenchyma can be demonstrated by roentgenograms of the chest. In the series reported, none of the individuals observed were known to develop an active tuberculous lesion of the lung. The lesions of erythema nodosum, the epituberculous lesions and the positive skin tuberculin reactions are similar histologically. As erythema nodosum is usually associated in children with early tuberculous infections, proper treatment for the latter condition gives a favorable prognosis as far as tuberculosis is concerned.

Antistreptococcus Serum for Patients with Rheumatic Fever.—If a hypothetic toxin or some peculiar bacterial fraction or autolysate is responsible for the various manifestations of the disease, Hitchcock et al. assert that these substances are elaborated in varying amounts and intensity over long periods; hence it is improbable that a serum effect, which at best can be of only short duration, would be ultimately successful. Their observations lead to the conclusion that antistreptococcus serum has no permanent antirheumatic influence and that acute antipyretic, antiarthritic and antitoxic effects can be obtained more certainly from salicylates or neocinchophen. Whether the favorable effects that followed a combination of these drugs with serum in a few cases of pericarditis were anything more than fortuitous is open to discussion. Of this one can be certain; that antistreptococcus serum has in no way replaced the long-established therapy of rheumatic fever, nor does it apparently add enough to warrant its universal adoption. The unpleasant reactions sometimes attendant on its application have not been outbalanced by a reciprocal certainty of therapeutic benefit.

Blood Transfusion in Acute Infectious Diseases.—One hundred cases have been studied by Landon. They include cases of diphtheria, scarlet fever, measles, pertussis, poliomyelitis, varicella, typhoid, streptococcus septicemia and postmeasles encephalitis. Blood transfusion appears to be contraindicated in diphtheria complicated by myocarditis, and in laryngeal diphtheria particularly when bronchopneumonia is present. It is a valuable adjuvant in the preoperative and postoperative care of mastoiditis, sinus thrombosis and empyema, particularly when these conditions are complications of scarlet fever or measles. It is of value in the treatment of bronchopneumonia complicating measles and pertussis. As a general tonic in protracted cases in which anemia and malnutrition develop, its use is strongly indicated.

Venous Murmurs in Hepatic Cirrhosis and Murmurs of Congenital Heart Disease.—Gwyn asserts that clefts in the sternum due to some defect in the process of ossification constitute a not uncommon anomaly. The collateral circulation that develops in the course of cirrhosis of the liver may easily provide venous trunks, which may pass through such clefts en route to sinuses of considerable size beneath the sternum. A loud murmur may be produced by the fluid eddies that will be present in such vascular connections. Such murmurs, if continuous and found in the neighborhood of the third, fourth or fifth interspaces of the left side, may well be confused with those of congenital heart disease. Before coming to any conclusion in connection with continuous murmurs over the heart area, finger pressure should be carefully applied to areas immediately adjacent to the sternum.

Chronic Cholecystitis.—A clinical study of a considerable number of cases of chronic cholecystitis has been made by Jones and Palmer for the purpose of correlating the "direct" and the "indirect" evidence of the presence of gallbladder disease. It has been shown that the proper correlation of these factors leads to a remarkably accurate clinical diagnosis of gallbladder disease—from 95 to 97 per cent of correct diagnoses. A method is given by which, with a high degree of safety, cases of chronic cholecystitis that should be considered surgical in type may be segregated. Based on the metabolic gradient theory of peristalsis, a logical explanation is given for the presence of most of the preoperative symptoms of chronic cholecystitis and also for the presence of the same symptoms remaining after operation. A workable method of postoperative medical treatment, based on this theory of peristalsis and on the constitutional type of the patient, is also given. The calcium oxide content of the gallbladder wall increases in percentage, for some unknown reason, as the gallbladder increases the density of its shadow on direct roentgen films. The content varies from an average of 0.02 per cent of calcium oxide, dry weight, in presumably normal gallbladders, which cast no shadow on the direct film, to an average of 0.16 per cent of calcium oxide, dry weight, in those gallbladders which cast a dense shadow on the direct film. No explanation is given for this finding, and its relation, if any, to shadow production on the direct film has not been determined.

Visceral Pain.—Rudolf and Smith aver that true visceral pain exists. It is usually dull but may be acute. Such visceral pain may occur alone or be accompanied by referred pain, which will appear in the distribution of the somatic nerves that come from the segment of the central nervous system with which the affected visceral nerves are connected. In many instances the referred pain is the only one that reaches the level of consciousness. Referred pain is more easily relieved than is that coming from the source of the irritation. This relief can be obtained by the use of various anodyne applications and especially by the infiltration of the skin by anesthetics, such as procaine hydrochloride. Often such anodynes will also, to a certain extent, relieve the deep suffering, but sometimes this is not the case and the afferent impulses from the source of irritation may, without any amplification from the periphery, be sufficient to reach the sensorium. When a referred pain is present it may be relieved either by attacking it at its distribution or, more specifically, by directly treating the cause of the irritation. The theory advanced here is that for referred pain to occur it is essential that the whole sensory reflex arc be intact.

*Immuniobiology in Diagnosis and Treatment of Pulmonary Tuberculosis. A. A. Lilien, New York.—p. 455.

Incubation Method of Sputum Concentration.—The results of 106,464 sputum examinations by the incubation-concentration method are reported by Sweany and Stadnichenko, of which 16,103 were positive. Fifteen per cent more positives were obtained by concentration than by direct smear in a control series of 1,500 specimens. No false positives were obtained in 6,283 examinations on negative controls consisting of observation cases, nontuberculous diseases and closed tuberculosis. Sixteen positive diagnoses were justifiably questioned because they did not conform to the clinical and roentgen observations at the time of the sputum examination. Of the sixteen, six were proved to be tuberculous; six were probably tuberculous; one was probably not tuberculous, but one in which the bacilli were avirulent or indifferent; while three were most probably errors in technic. This virtually leaves 4 errors in 16,103 positives, or 1 in about 4,000. Atypical acid-fast forms, when found alone, should be considered only suspicious until proved otherwise. There appear to be no more sources of error with this method than there are with any other method of similar technical manipulation.

Serum-Calcium in Pneumonoconiosis.—In a group of thirty patients with pneumonoconiosis studied by Sokoloff and Cantarow, fifteen of whom had an associated active tuberculous lesion, the serum-calcium ranged from 7.98 to 14.81 mg. per hundred cubic centimeters, being above normal in twenty-six patients, subnormal in one, and normal in three. The serum-calcium level bore no relation to the incidence or activity of the complicating tuberculous process. It is believed that the hypercalcemia in pneumonoconiosis is in all likelihood dependent on the increase in the carbon dioxide tension of the blood, which is an inevitable consequence of the pulmonary lesion.

Immunobiology in Diagnosis and Treatment of Pulmonary Tuberculosis.—Lilien finds that immunobiology in tuberculosis affords in some cases an early diagnosis in the preclinical stage and helps to explain the development of immunity, the biologic stage of the struggle in the given individual, and the prognosis. Therapeutically, in a great number of cases immunobiologic means can be advantageously used, together with other means in the fight against tuberculosis.

Excretion of Bismuth.—The clinical excretion of bismuth after the intramuscular injection of comparatively small therapeutic doses of potassium bismuth tartrate and of bismuth salicylate, both in oil, was found by Hanzlik and Mehrtens to be prompt but slow, irregular, variable, prolonged and incomplete. After the injection of potassium bismuth tartrate, the peak of daily excretion was reached on the twelfth day after a single dose (0.056 Gm. of bismuth) and on the fifteenth day after two and three doses (0.112 and 0.168 Gm.) after the first injection. The maximum daily excretion of bismuth after one dose was 0.5 mg., after two doses 3.6 mg., and after three doses 2.4 mg. After the injection of bismuth salicylate, the peak of daily excretion was reached on the fifteenth day after a single dose (0.075 Gm. of bismuth) and on the tenth day after four doses (0.312 Gm.). The maximum daily excretion of bismuth after one dose was 1.5 mg., and after four doses 1.3 and 4.5 mg., respectively, in two subjects. The urinary excretion of bismuth after the use of potassium bismuth tartrate lasted at least seventy-two days after two doses and forty-two days after three doses; after bismuth salicylate, at least twenty-six days after one dose and seventy-nine days after four doses. The duration of excretion did not appear to be related to the dosage. The total urinary excretion of bismuth after the use of potassium bismuth tartrate was 54.6 per cent after two doses and 24 per cent after three doses; after bismuth salicylate, 25 per cent after one dose and 44.5 per cent after four doses. The bismuth unaccounted for remains in the body as a depot at the site of injection and in the viscera, traces being excreted probably for months. The median daily excretion of bismuth in feces after injection of potassium bismuth tartrate was about one twelfth of that in urine, the range being from 1 : 27 to 1 : 2; after bismuth salicylate the median was 1 : 8, the range being from 1 : 14 to 1 : 1.5.

Perspiration: Bismuth.—The sweat of four patients undergoing an intensive course of treatment with bismuth was found by Schaffer to contain no bismuth. Urine from the same subjects showed the presence of bismuth in amounts of from 0.6 to 1.5 mg. per hundred cubic centimeters. Blood of one subject was examined and did not show the presence of bismuth.

Dermatophytid Complicating Tinea Cruris.—A report is given by Williams of an eruption following the typical course of dermatophytid, and an appearance common in that eruption, consecutive to severe tinea cruris. It is believed to be the first case of the kind recorded.

Perlèche of Adults.—Five cases of perlèche are reported by Skolnik. They were all bilateral and chronic and were in adults. Organisms, identified as cryptococci, were cultivated from the lesions in each case. Inoculation of a pure culture of cryptococcus made under the normal breast produced a lesion similar to those at the angles of the mouth, which disappeared spontaneously within from three to four weeks. Cryptococci were isolated from this experimentally produced erosion on the first of three attempts, which was on the fifth day. No yeasts grew from scrapings cultured on the tenth and fifteenth days. Control cultures made from the angles of normal mouths revealed only bacteria.

Pyoderma (Echthyma) Gangrenosum.—An unusual type of ulceration of the skin is described by Brunsting et al. as occurring in five adults who were debilitated by reason of some infectious process elsewhere in the body. Four of the patients had chronic ulcerative colitis of years' standing; the other had chronic empyema. A striking parallel relationship was demonstrated between the activity of the cutaneous lesions and the major infectious focus, the intestine. Results of clinical and histologic studies compare favorably with those previously reported in studies of certain types of pyoderma. The similarity of this condition, amebiasis cutis and hemolytic streptococcus gangrene of the skin and subcutaneous tissues is considered. Amebas were not demonstrated in cutaneous lesions or stools. On the other hand, hemolytic streptococci and staphylococci were found with consistent regularity in the secretions from the ulcers and in the deeper tissues of specimens removed for biopsy. Intradermal inoculation of rabbits with the combination of the foregoing organisms produced an ulcerative area similar to the undermining lesions seen in the patients. The authors believe that the cutaneous manifestations described as pyoderma gangrenosa are but one part of a generalized infectious syndrome characterized by a marked lowering of bodily resistance to the invading organisms. Healing of the cutaneous lesions is dependent on the successful treatment of the systemic disease.

Lichen Nitidus Treated with Gold Sodium Thiosulphate.—The most striking point in Niles's report is that a case of lichen nitidus, a disease supposed by many to be of tuberculous origin, cleared up during the administration of gold sodium thiosulphate, although true tuberculosis of the skin rarely, if ever, responds to this treatment. A parallel might be drawn with lupus erythematosus, which likewise has been presumed to be of tuberculous etiology and yet reacts uniformly well to aurotherapy.

Takata-Ara Colloidal Test with Spinal Fluid.—From clinical experience with the Takata-Ara test Karnosh and King conclude that the test is not highly specific. While it is positive in about 82 per cent of the cases of metasyphilis, there is enough disagreement to make its value as a routine test in syphilis rather doubtful. It is frequently positive in other organic, nonsyphilitic conditions, such as cerebral arteriosclerosis, brain trauma and tumor. Although, in comparison with other colloidal reactions, the test is simple to carry out and to read, it has no advantage over the Weichbrodt reaction.

Influence of Intercurrent Febrile Disorders on Preexisting Epilepsy.—Among eighty-five patients with influenza, Guthrie says that slightly more than half showed a decrease in the number of convulsions following this disease; however, the total number of convulsions in all cases was slightly increased. Among seventeen patients with scarlet fever, a great majority had more convulsions after the acute illness than before, and the total number of convulsions increased following the acute infection; however, the decrease in number of seizures during the month of acute illness was most noticeable. After chickenpox, erysipelas, tonsillitis and diphtheria there was a slight decrease in the number of convulsions, but the number of patients showing this relative improvement was so limited that these apparently favorable results are considered practically negligible. The decrease in the number of seizures that occurred in 200 cases followed over 10.6 months before and 10.6 months after an acute febrile disorder was only 3.6 per cent. A gradual decrease has been noted in the frequency of seizures in patients showing progressive deterioration with definite neurologic signs. This probably offsets the almost negligible decrease in seizures (3.6 per cent) following acute febrile states. The most prominent feature of this analysis is the decrease in the number of seizures in most cases during the month of illness, and this is reflected in the comparison of total averages before, during and after the acute illness. The decrease in the number of seizures during the month of illness, as compared with the average monthly rate of convulsions for 10.6 months before and 10.6 months after the acute illness, amounts to 18.5 per cent. By grouping the respiratory diseases together (107 cases of influenza, pneumonia and whooping cough), the change in frequency of seizures is found to be slight. In these 107 cases the average monthly rate of convulsions previous to the acute illness was 5.9, during the month of acute illness 5.9, and following the acute illness 6.4. This gives an increase of 7.8 per cent after the febrile period and no decrease in convulsions during the month of illness as compared with previous months. The changes, then, are found chiefly among cases of nonrespiratory diseases, scarlet fever, mumps, measles, chickenpox, erysipelas, tonsillitis and diphtheria. In this group, composed of ninety-three cases, the monthly rate of convulsions previous to the acute illness was 6.9, during the month of acute illness 4.2, and following the month of acute illness 5.7. These figures give a decrease of 17 per cent following the acute illness as compared with the rate before the acute illness. In this group there is also a decrease in seizures of 33.33 per cent during the month of acute illness as compared with the average rate before and after the acute disease.

Encephalitis and Influenzal Pneumonia Following Vaccination.—A case of encephalitis and influenzal bronchopneumonia occurring in a child twelve days after vaccination for variola is described by Tuthill. Since influenzal encephalitis as an entity has not been established, the clinical diagnosis rested between a sporadic case of encephalitis epidemica and postvaccinal encephalitis. The histopathologic observations in the brain were not similar to those found in epidemic encephalitis, since there was no perivascular infiltration of the gray substance around the ventricles and sylvian aqueduct, except in the lateral areas of the thalamus and the caudate nucleus. The chief areas of perivascular infiltration were in the centrum ovale. The infiltrations in the basal ganglions, the pons and the cerebellum were slight. There were no infiltrations in the meninges, the cord or the medulla oblongata. In spite of some dissimilarity to the reported cases of postvaccinal encephalitis, the histopathology on the whole conforms to that of this disease.

Immunity to Poliomyelitis in Mothers and New-Born.—Neutralization tests made by Aycock and Kramer for the virus of poliomyelitis on blood serum of urban mothers and their new-born infants showed that immunity was present in ten out of twelve (83 per cent) infants and in ten out of twelve (83 per cent) mothers, with a complete correspondence between mother and infant. These tests point to passive transmission of immunity from mother to infant. Previous tests on other children (aged from 1 to 5 years) indicate that immunity in infants is transitory. Previous observations concerning the extent of immunity in urban adults are confirmed and extended. The results of these tests are in accord with the age distribution of poliomyelitis and parallel corresponding observations in diphtheria.

Cultivation of Vaccine Virus.—A strain of neurovaccine virus was cultivated by Li and Rivers in a medium consisting of minced chick embryo suspended in Tyrode's solution. The virus on cultivation apparently lost none of its essential characteristics. The culture virus can be preserved and stored for long periods of time. Furthermore, the preserved virus can be used to initiate fresh cultures.

Host Factors in Pathogenesis of Pneumococcus Pneumonia.—Sharp and Blake endeavor to determine whether animals exhibiting cutaneous hypersensitiveness to pneumococci would show an acute inflammatory reaction in the lungs when pneumococcus autolysate was brought into contact with the pulmonary tissues and, if so, whether the pulmonary reaction might be shown to be due to the allergic state of the animal, rather than to intrinsic properties of the autolysate. From their results it may be concluded that there is in rabbits a fairly close parallelism between cutaneous and pulmonary hypersensitiveness to pneumococcus autolysate and that the inflammatory response of the pulmonary tissue resulting from contact with the autolysate depends on the allergic state of the animal rather than on inherently injurious substances in the autolysate. The observations are in harmony with the theory that allergy may play a part in the pathogenesis of pneumococcus pneumonia in man.

Cutaneous Reactions in Pneumonia.—Francis and Tillett assert that the majority of patients convalescent from pneumonia due to types I, II and III pneumococci develop at the time of recovery circulating antibodies for the homologous type of organisms. At the same time an immediate wheal and erythema reaction followed the intradermal injection of the homologous type-specific polysaccharide in 100 per cent of type I patients, 58.8 per cent of type II patients, and 44 per cent of type III patients. In a group of eighteen patients repeatedly tested with the type-specific polysaccharides, ten developed in the second or third week of convalescence circulating antibodies for one or more heterologous types. In none of twenty-one control patients was this phenomenon observed. It is suggested that the development of circulating antibodies for heterologous types of pneumococci was associated with the previous intradermal injections of the type-specific polysaccharides.

Bacterium Granulosis in Relation to Trachoma.—Six additional strains of *Bacterium granulosis* have been isolated by Tilden and Tyler from cases of trachoma occurring in the Indian schools of Arizona. The cultures thus obtained are identical morphologically and culturally with those isolated by Noguchi and have induced the same chronic granular conjunctivitis in monkeys. Several additional cultural and biologic characteristics of *Bacterium granulosis* are described. Of importance is the fact that cocaine, in contradistinction to procaine, has a bactericidal effect on the organism. This fact, in view of the common use of cocaine for anesthesia, may explain the negative results of cultivation experiments reported by some workers.

Syndrome of Amyotrophic Lateral Sclerosis in Epidemic Encephalitis.—A case of acute epidemic encephalitis soon followed by bulbar palsy and later a syndrome of amyotrophic lateral sclerosis is reported by Ornsteen. A prominent feature of the case is universal myoclonia affecting all of the muscles of the body from the masseters and buccinators down to the calves. Lesions of the anterior horns and pyramidal tracts are inferred to explain the amyotrophic lateral picture, and the pathologic findings by Wimmer in two similar cases are offered in evidence. Lesions of the mesencephalon are considered to be the cause of the universal myoclonia rather than ganglion cell irritation in the motor nuclei of cranial nerves and anterior spinal horns. Amyotrophic lateral sclerosis may be related to an ancient infection. Authoritative opinions as to the nature and causation of amyotrophic lateral sclerosis are reviewed.

Infarcts of Cardiac Origin.—Mortensen asserts that the greater percentage of infarcts are of cardiac origin, thrombosis occurring in the heart in the following order of frequency: (1) right auricle; (2) left ventricle; (3) left auricle; (4) right ventricle. Thrombosis in either side of the heart may produce infarcts in both pulmonary and peripheral circulation when a patent foramen ovale exists, but these cases are rare. The three types of emboli originating in the heart are (1) small mycotic vegetations associated with endocarditis; (2) a large type of emboli that develop where circulation is retarded or stagnant, as in auricular appendages, apexes of ventricles, and between columnae carni; (3) ball thrombus, which is rare and always in the left auricle and associated with mitral stenosis. Blood platelets are believed to be the nucleus of a thrombus, an accumulation of these being caused by injury (bacterial or otherwise) to endothelial surfaces. Stasis in the blood stream is a predisposing factor, and cardiac disorder nearly always precedes the formation of thrombi. Types of cases in which thrombosis and emboli are liable to occur are discussed, and the management of cases is outlined.

Gastric Ulcer and Carcinoma as Revealed by Roentgen Studies.—Feldman asserts that a stereotyped, fixed or straight line appearance of the curvatures of the stomach as revealed by roentgen examination occurs as the result of a thickening, induration and infiltration of the tissues of this organ. Diminished or absent peristalsis or a break in the peristaltic wave is probably the earliest roentgen sign of gastric disease. A small stomach, located high, presenting the fixed and stereotyped appearance, emptying rapidly, even though showing no filling defect, is frequently the result of a carcinoma at the cardia. Spasm is frequently the result of a gastric lesion; the incisura is a typical example. It occurred in 16 per cent of the cases of ulceration. The presence of a filling defect is not always necessary in order to establish the roentgen diagnosis of a gastric lesion. The proper interpretation and evaluation of the roentgen signs here described is highly important in the early diagnosis of gastric disease.

Paravertebral Abscess: Early Roentgen Sign of Tuberculous Spondylitis.—Cases are cited by Rigler et al. as proof that paravertebral abscess occurs commonly in tuberculosis of the thoracic vertebrae but is clinically unrecognized in many cases. Its roentgen diagnosis is important because it is almost pathognomonic of tuberculosis spondylitis. It may be the earliest roentgen sign of tuberculous spondylitis appearing before there are any visible changes in the bodies of the vertebrae. Two cases of this type are reported. It may be present in characteristic form while the changes in the vertebral column are still minimal or not entirely diagnostic roentgenographically. Two cases of this type are reported. Paravertebral abscess may overlap the shadow of the heart in the ordinary chest roentgenogram, simulating a mediastinal process.

Concept of Arthritis.—Mayers concludes that arthritis is a chronic infective condition, in which the joint manifestations are the end-products of a long period of intoxication, which intoxication results from an infective process usually with the streptococcus.

*Origin and Significance of Tuberculosis of Tracheobronchial Lymph Nodes of Lung. L. R. Jordan.—p. 225.

Epilepsy.—Blachford concludes from his review that: 1. Ordinary grand mal is produced by impulses that arise in the neostriate body and act on the cortex. 2. The mental condition of epileptic patients immediately preceding and in the intervals between the seizures is due to irritation of cortical sensorimotor cells by impulses originating in the striate body. 3. The neostriate body, consisting of the putamen and the caudate nucleus, is the center for the association of the muscle sense with the other senses. And as a corollary that: 4. Drugs which act primarily on the basal ganglions in epilepsy are to be preferred to those which act directly on the cortex, as being more efficient and less likely to damage the more highly developed but less definitely organized cortical cells.

Five Years of Surgery in Exophthalmic Goiter.—In Short's opinion, all patients with toxic adenoma of the thyroid should be operated on, and all patients with classic exophthalmic goiter after a year's duration, unless mentally deranged. There is a good deal of reason for operating also in early cases. Auricular fibrillation and glycosuria will probably clear up after subtotal thyroidectomy.

Changes in Spleen in Acute Pyogenic Infections.—One hundred and eighty cases of acute infections, irrespective of whether they were said to present "acute splenic tumors" or not, were analyzed by Hewer in order to determine the degree of splenic change by observing the relative number of large mononuclear cells present in the pulp. The results of this study show that in acute pyogenic infections splenomegaly is due to an increase in the number of cells in the pulp, and in the malpighian bodies in some cases. The most striking cells that are present are large basophilic nongranular mononuclear cells, which are identical with myeloblasts. The degree of splenic change corresponds with the leukocytosis. The identity of the infecting organism is of less importance *quâ* the spleen than the grade of leukocytosis it produces. Pyrexia alone does not produce "acute splenic tumor." The production of "acute splenic tumor" is not essential for, or directly related with, antibody formation.

Tuberculosis of Tracheobronchial Lymph Nodes of Lung.—Analysis and study of thirty-three cases has convinced Jordan that the majority of evidence at present points to tuberculous infection of the tracheobronchial glands being secondary to a primary air-borne infection in the lung tissue. Tuberculosis, especially of the tracheobronchial glands in children under 5 years, is not dormant, but in the majority of cases ends in fatal disease. A considerable proportion of acute miliary tuberculosis, especially with tuberculous meningitis, in adults has its origin in tracheobronchial tuberculosis. All the cases of tuberculous meningitis were blood-borne, and no explanation is offered for the absence of visible primary foci in these cases. Tuberculous infection in childhood increases resistance to the disease but at the same time is a source of danger.

Osteoclast with Screw Control. A. MacLennan.—p. 690.

Guanidine-Like Substances in Blood in Yellow Fever.—Findlay and Hindle conclude from their experiments that in experimental yellow fever in monkeys there is an increase in the blood content of guanidine-like substances, similar to that associated with other conditions involving liver necrosis. The increase in guanidine-like substances can be reduced by the administration of calcium lactate. Calcium lactate does not prevent death in monkeys suffering from yellow fever but does tend to prevent hemorrhages.

Excretion Urography.—When a cystoscope cannot be passed or ureteral catheterization (or any instrumentation) is undesirable, difficult or impossible, Cooke says he has at his disposal an alternative method of visualizing the renal pelvis and calices. In the presence of ureteral obstruction a clear ureterogram may be secured. The method may be of value in the investigation of the urologic case in the child; in cases of severe cystitis—tuberculous or otherwise—in which catheterization is difficult; in cases of profuse hematuria; in cases of urethral stricture and enlarged prostate; and in the subsequent examination of a kidney, the ureters of which have been transplanted. The shadow cast by the excreting renal substance itself is enhanced during the excretory process, so that the size and shape of the kidney substance are often clearly seen. The excretion rate and the intensity of the pyelograms give a graphic representation of the function of each kidney at the time. This fact in itself may be valuable in dealing with certain cases, such as hydronephrosis with blocked ureters. The excretion rate, which represents the total renal efficiency at the time, may be ascertained by measuring the output in the urine, or, more simply, by following the alterations in the specific gravity of the urine. This has not been found of much practical value. It is important in interpreting the results from the standpoint of function to bear in mind that the functional activity of a kidney can be temporarily inhibited, and the nonvisualization at a particular examination does not necessarily mean a permanently damaged kidney. The method has its limitations, since the shadows depend on renal function, and therefore no shadow, or an undecipherable one, may be obtained in pathologic renal conditions. To make a precise diagnosis, recourse to the older method may be necessary, and since in many cases cystoscopy is absolutely essential it is still quicker (and cheaper) to proceed to ureteral catheterization and retrograde pyelography in the average case. Excretion urography is as yet somewhat expensive and uncertain. There must always needs be a percentage of failures, but undoubtedly a most valuable accessory investigatory method has been placed in the hands of the profession.

Adenomyxomatous Polypoid Tumor of Stomach. G. N. Clark.—p. 740.

Pulmonary Tuberculosis in General Practice.—Wood stresses this idea: When a young person of either sex complains of a cough with expectoration, tuberculosis must always be borne in mind. It can be excluded with some confidence if five negative conditions are satisfied. It is unlikely that tuberculosis is responsible for the cough if: (1) there is no history of pleural effusion; (2) there is no history of hemoptysis; (3) no crepitations are heard after coughing in any danger zones; (4) no tubercle bacilli are found in three successive sputum examinations; (5) roentgen examination is negative. If the first four conditions are satisfied a short period of observation with expectant treatment may suffice, but if the practitioner's suspicions are aroused by the patient's appearance or manner, by a history of contact with infection, or by the continuance of symptoms for more than a fortnight, a roentgenogram is essential. If the services of a radiologist with special experience in chest work are not available, a second opinion should be obtained. In some cases a short period of institutional observation may be advisable.

Thrombophlebitis Migrans.—Thrombophlebitis migrans is defined by Ryle as a disease in which phlebitis appearing usually in small lengths of superficial peripheral veins is sometimes followed by symptoms of inflammation with small vascular obstructions in the lungs, the abdomen, and more rarely in the heart and the brain. Visceral thromboses may also precede or occur without superficial lesions. The disease tends to run a long and tedious and often interrupted course. Fever and leukocytosis commonly accompany each fresh development. Although it may give rise to serious illness and much anxiety, the prognosis is favorable, presumably because the thromboses are venous, because they do not as a rule spread to larger trunks, and because there is no associated septicemia. The pulmonary thromboses may be heralded by agonizing bouts of spasmodic pain or by ordinary pleuritic symptoms which precede hemoptysis, when it occurs, by hours or days. A faintly turbid and blood-stained pleuritic effusion sometimes follows. The abdominal thromboses are characterized by pain and distention and occasionally by melena. The symptoms of the cardiac and cerebral thromboses do not differ from similar lesions of other causation, but, as small veins rather than arteries are probably involved, prognosis again need not necessarily be regarded as unfavorable. Treatment is expectant and symptomatic. Liberal fluids and potassium citrate may reasonably be prescribed. Obvious focal infections should receive attention at the proper time. Perhaps the most important single conclusion to be drawn from a study of these cases is that thrombophlebitis of this type is to be remembered as an occasional cause of cerebral, cardiac, pulmonary and abdominal accidents that might otherwise prove difficult to explain. Five cases are reported by Ryle.

Treatment of Deafness by Zund-Burguet Method. R. H. Bettington.—p. 366.

Local Venesection in Treatment of Snake Bite.—Experiments made by Kellaway on sheep injected with the venoms of the death adder and tiger snake have demonstrated the value of treatment by local venesection when this can be applied immediately. Those with copperhead and brown snake venoms were less satisfactory. Protection was afforded against from one to one and a half certainly lethal doses of the venoms of the death adder and tiger snake and against from one to one and a fourth certainly lethal doses of the venoms of the brown snake and copperhead. The ligatures in these experiments were applied above the carpal joint in the forelimb and therefore the blood flow to the ligated part, though nearly, was not always completely obstructed. This did not seriously affect the results when venesection was carried out at once, but when treatment was delayed to make the experiments more comparable with practical conditions the results were not so satisfactory. The certainly lethal doses of brown snake venom by subcutaneous and intravenous injection have been determined for sheep. The "thrombase" of this venom is extremely potent in this species, the subcutaneous-intravenous index being approximately 20. Despite this high index, treatment by simple ligature round the metacarpal bone was not effective. The "thrombase" of brown snake venom is apparently highly diffusible and, when injected subcutaneously or even intradermally, finds its way rapidly into the venous blood in sufficient concentration to cause death by intravascular coagulation. In bites by the brown snake it is urgently necessary to apply the ligature immediately and excise the bitten area. Treatment by venesection, as soon as this is practicable, should prove of definite value in cases in which excision has not been done. It is unlikely that univalent antiserum will ever be available for treatment of the bites of this snake or of other species of the genus *Demansia*. These experiments afford further evidence of the absorption of Australian snake venoms directly into the blood stream.

*Significance of Quantitative Intradermal Tuberculin Reaction in Prognosis of Tuberculosis. J. W. Lobban.—p. 19.

Tuberculin Reaction in Prognosis of Tuberculosis.—From the results obtained with the intradermal tuberculin test in the tuberculous and in the control series of cases, Lobban is led to believe that the earlier the stage of disease and the less the degree of infection, a positive reaction can be obtained with a greater dilution of tuberculin. As the disease advances the patient fails to react to the greater dilutions, and lesser dilutions are necessary before a positive reaction can be obtained. Further, it becomes apparent that the intradermal tuberculin test in tuberculosis, when repeated at intervals, shows a more marked reaction when the condition is improving, and fails to appear or become positive when a lesser dilution is employed when the condition is retrogressing. It is thus a guide as to progress in addition to the clinical signs. A test that becomes more marked in reaction, e. g., from + to ++ or +++, gives an indication that the lesion is improving and is of good prognostic value, whereas when a patient fails to react to the original dilution of tuberculin used and repeatedly fails to react with a lesser dilution, the outlook is not hopeful.

Serologic Relationship Among Yeastlike Fungi.—A simple and sensitive method for the serologic study of several strains of monilias and *Saccharomyces* has been found by Lim and Kurotchkin through the use of the water soluble specific substance. The different monilias form a homogeneous group of organisms, the individual species of which are found to be closely related according to their cross serologic reactions. Monilias and *Saccharomyces* cannot be differentiated on the basis of their cross serologic reactions. The high sensitivity of the water soluble specific substance derived from the monilias and *Saccharomyces* suggests the use of this substance as an antigen in the serologic diagnosis of human infections due to yeastlike fungi.

Giardia Intestinalis in North China.—An analysis is given by Tao of 649 cases of positive *Giardia* infection examined at the Peiping Union Medical College Hospital from 1925 to 1930. A definite relationship between *Giardia* infection and gastro-intestinal symptoms could not be established. There are 249 patients, or 38.37 per cent, with gastro-intestinal symptoms and 400, or 61.63 per cent, without gastro-intestinal symptoms. The percentage of diarrhea is markedly high in young children. It gives 48.34 per cent of children from 1 to 5 years of age, 22.86 per cent of children from 6 to 15, and 15.75 per cent of adults. Children from 1 to 15 years of age are found to show 23.82 per cent of dyspepsia and 19.59 per cent of diarrhea in pure infection and 13.77 per cent of dyspepsia and 10.18 per cent of diarrhea in mixed infection. One has, however, to keep in mind that diarrhea is a common complaint in young children.

Sclerema Neonatorum.—The subcutaneous fat and the fat-free skin of eight sclerema and four nonsclerema babies were analyzed by Chen. The fats showed no difference in melting point, solidifying point, iodine number, saponification value and acetyl number. The calcium and phosphorus contents of the fat-free tissues of the normal and sclerema babies were also about the same. These observations do not lend support to the hypothesis that sclerema neonatorum is caused by a chemical change of the cutaneous tissue.

Causes of Blindness Among Chinese.—From May, 1928, to April, 1929, 336 (10.2 per cent) blind patients were seen among 3,279 admissions to the eye clinic of the Peiping Union Medical College Hospital. In 18.9 per cent of these blind persons the cause of blindness could not be ascertained. The main determinable causes were in the following descending order of frequency: keratomalacia, 34.5 per cent; trachoma, 14 per cent; glaucoma, 8.9 per cent; syphilis, 5 per cent; cataract, 5 per cent; gonorrheal ophthalmia, 5 per cent; injuries, 4.2 per cent; tuberculosis, 2.1 per cent; neoplasms, 0.6 per cent; smallpox, 0.3 per cent. With the exception of keratomalacia and an interchange of place of glaucoma and cataract, the main causes of blindness occupied the same relative position in Ling's series and in Chang's analysis of cases. Keratomalacia was an insignificant cause, 0.52 per cent (in only four eyes) in Ling's 760 blind patients, while it was responsible for 116 of Chang's series of 336 blind, or 34.5 per cent. The cause of this remarkable difference is chiefly the civil war, as a great number of eye patients during the last year were soldiers. On account of the restricted finances of the armies and the difficulty of seeking aid in the early stage of the disease, keratomalacia spread.

Gonococcic Allergy. F. Benoist.—p. 174.

Muscular Uremia.—Gounelle describes several cases of muscular uremia that he has observed and mentions a number of cases described by other authors. The disease presents two distinct clinical forms, myoclonic and myotonic, according to the nature of the muscular reactions involved. In both forms one observes the usual symptoms of uremia: torpor, somnolence, coma, gastro-intestinal disturbances, vomiting, diarrhea, and at times constipation, hypothermia, myosis, oliguria and albuminuria. Hypertension is not always present; however, when it does occur it may be regarded as a pathognomonic symptom in connection with the rest of the clinical picture. The myoclonic form is characterized by intermittent clonic contractions in various muscles and muscular groups. The contractions are practically painless and may affect any part of the body, although the four limbs, especially the arms, are most frequently attacked. Hiccups also occur frequently. In the myotonic form the contractions are persistent, involuntary and always painful; in other words, a "cramp." They vary in intensity and duration and may be localized in any group of muscles. Sometimes a meningeal syndrome resembling meningitis appears in which the spasm attacks the spinal region; this can usually be distinguished from meningitis, however, by the fact that in muscular uremia the cerebrospinal fluid is almost always normal. The spasm is sometimes so generalized that it resembles a state of tetanus; even opisthotonos may appear and during it the patient frequently dies. A trustworthy diagnosis may usually be made by observing the specific muscular syndrome in connection with the classic pathognomonic indications of general uremia. It is necessary to distinguish the myoclonic form from the epileptic form. The latter, however, is usually due to hydropigenous nephritis, hypertension or retention of chlorine in the cerebral gray matter and presents different clinical symptoms. The pathogenesis of muscular uremia is not yet fully established. Probably the soundest and best tested theory is that it is caused by azotemia. There is some basis also for the theory of cerebral retention of chlorine. The author suggests that in many ways the condition resembles the results of parathyroid insufficiency.

*Anacrotic Pulse. C. Laubry, P. Soulié and A. van Bogaert.—p. 561.
Electrocardiographic Translation of Auricular Preponderance in Mitral Stenosis. I. Chvartzman.—p. 603.

Anacrotic Pulse.—The contradictory views expressed by various authors led Laubry et al. to make a thorough study of the problem of anacrotism of the pulse in order to determine its exact nature and origin. For the experiments they used a pneumatic cuff connected with a manometer and a Pachon-Boulitte oscillometric ampule. The inscription was made either by the optical method or on smoked paper. The manometer made it possible to read the pressure under which the graph was made. After a long series of tests the authors are convinced that true anacrotism of the pulse is due to the exaggeration on the arteriocardiogram of the secondary systolic wave, coincident or not with the decline of the primary wave. This anacrotism, corresponding to that of the heart, is the expression of conflict of an intense and prolonged ventricular effort, projecting its blood wave into a resisting arterial system. The conflict causes an irregularity in the form of a camel's back in the cardiogram and the exaggeration of the second systolic wave of the arteriogram. Since anacrotism is a function of peripheral resistance, myocardial effort and the amount of blood expelled, it is exaggerated when the three influences act together and it disappears when they are weakened, especially when the myocardial element is lacking. The secondary systolic wave surpasses the summit of the primary wave more easily when the latter is low. Anacrotism of the pulse and heart is not a sign of severe myocardial deficiency but is the graphic representation of an abnormal though easily tolerated peripheral condition. One observes a physiologic anacrotism in the arteriograms taken at minimal pressure, an experimental pseudo-anacrotism engendered by a stenosis of the arterial system, and a latent or concealed anacrotism in connection with pure aortic stenosis.

*Transplantation of Patella. P. Moulonguet.—p. 175.
Subcalcaneous Exostosis. F. Ferrari and F. Morand.—p. 180.

Transplantation of Patella.—Moulonguet regards transplantation of the patella as the operation of choice to remedy a loss of muscular substance in the lower part of the femoral quadriceps. If the defect is filled with grafts of muscular tissue, the quadriceps is weakened and adherences and ossification are also likely to result, which prevent bending of the knee. On the other hand, the transplantation of the patella to meet the quadriceps, with reinsertion of the muscle, gives excellent anatomic and functional results. This operation was first performed by Lecène, who used the following method: A prefemoral incision is made in the shape of the letter Z. The large fragment is turned down outside. The diseased portions are removed. The patella is completely freed at each side. Section of the tendon is made at two levels extending across almost the entire width of the tendon, this lengthening it sufficiently. The patella is then raised so that it may be sutured to the lower end of the quadriceps. The edges of the patella are also sutured to the external fibers. The patella is thus completely reinserted and the articulation closed. Within a few months the patient is able to walk with ease and full mobility of the knee.

Kümmel-Verneuil Disease. O. Francke.—p. 431.
Total Hysterectomy in Cancer of Neck of Uterus. R. Labry.—p. 445.

Secondary Cancer of Peritoneum.—Cottalorda and Caire describe twelve cases of secondary cancer of the peritoneum that they have studied. Although the disease is practically always fatal and seems to be beyond the resources of surgical treatment, they have found that in most cases an exploratory laparotomy may be made with safety, which sometimes reveals tumors that may be removed. They feel, moreover, that if it were possible to make an earlier diagnosis a method of treatment might be possible. With this in mind, they consider an exact knowledge of the anatomic and clinical characteristics of secondary cancer of the peritoneum well worth while. The condition is the result of a primary growth in the genitalia or the stomach that extends to the various regions of the peritoneum. The three chief symptoms are ascites, tumors and intestinal occlusion. The abdomen is greatly enlarged and filled with a bloody fluid that contains leukocytes of various types, hemolyzed erythrocytes, lymphocytes, and some rare polymorphonuclears, and that renews itself rapidly after puncture. The tumors themselves are made up of masses of grayish white granulations and are in general the size of an orange or a fetal head. They are usually attached to the abdominal wall, which itself has a covering of the same granulations, but are in rare instances found floating in the fluid. They are usually observed in the subumbilical region near the hypogastrium or the iliac fossa but sometimes in the two hypochondria. The occlusion of the small intestine that results is caused sometimes by adhesions or tumoral compression but usually by a neoplastic retractile mesenteritis that draws the small intestine backward and flattens it firmly against the posterior abdominal wall. However, the common clinical manifestations of this intestinal occlusion make accurate diagnosis difficult. The various forms in which the disease appears in the clinic as well as the fact that the symptoms do not become specific until the cancer is well developed are also obstacles that hinder the early diagnosis that is desirable.

Presse Médicale, Paris

38: 1217-1232 (Sept. 10) 1930

*Errors in Application of Insulin Treatment in Diabetes. M. Labbé.—p. 1217.
Pulmonary Silicosis. A. Feil.—p. 1220.
*Hernial Contusions. R. Chabrut.—p. 1223.

Errors in Application of Insulin Treatment in Diabetes.—Although the correct method of insulin treatment has long been established, Labbé feels that there are still many misconceptions of the nature and application of this treatment prevalent among both laymen and physicians. He discusses several of these, as follows: 1. The fallacious belief that insulin in itself can cure diabetes has led physicians to employ this treatment with no attention to diet, in abnormal quantities, or at irregular intervals rather than constantly. This is, of course, useless and even dangerous, since the action of insulin merely reestablishes the alimentary metabolism by permitting the utilization of from 1 to 1.25 Gm. of carbohydrates for each unit of insulin injected. It does not remove the cause of the diabetes but merely controls from day to day the hyperglycemia. 2. The fact that abandoning insulin treatment causes severe and often fatal results has intimidated certain physicians and caused them to avoid the prescription of insulin. It is true, to be sure, that it is dangerous to discontinue the treatment, but the danger is due not to the fact that insulin has been used but to the seriousness of the diabetic condition itself, which would have proved fatal without the use of insulin, whereas the treatment allows the patient to live in apparent health. 3. The reactions of hyperinsulinism or hypoglycemia which often result are alarming to many. The author, however, has never observed any really serious effects, although patients often relapse into a state of coma for a few minutes. Even this may be avoided if injections of insulin are given a quarter of an hour before eating and a quantity of carbohydrates corresponding to the dose of insulin is included in the meal. 4. To avoid the constant injections that are so distasteful to many patients, numerous methods of administering insulin have been introduced. The only effective method, however, is the long established one of subcutaneous injection. Labbé particularly condemns the present propaganda for insulin tablets, many varieties of which are now on the market. Insulin in this form can have little or no effect, and the abandonment of injections for tablets taken by mouth has caused disastrous results in a number of patients.

Hernial Contusions.—Chabrut describes several cases that show what serious results can follow even a slight contusion of a hernia. Whether the contusion is followed by a strangulation (complete or incomplete), a generalized peritonitis or a hemorrhage, the only safe rule to follow is to operate as quickly as possible, even when reduction of the hernia takes place spontaneously. Early operation is especially important when peritonitis is involved; for instance, in ten cases observed, only two patients survived, on both of whom operation was performed within two hours after the contusion.

Functional Examination of Biliary Passages by Roentgen Exploration After Cholecystotomy. L. Bérard and P. Mallet-Guy.—p. 614.

Surgical Treatment of Sigmoiditis.—Delore reports seven cases of sigmoiditis and draws the following conclusions as to the surgical methods that are most efficacious in combating the disease: In acute gangrenous forms, treatment should be limited, in general, to drainage by means of an artificial cecal or colic anus; resection is rarely practicable. When a perisigmoidal abscess is present, one should first incise and drain the abscess; later, especially when diverticulitis is present, a secondary resection is often necessary, which to be harmless should follow certain rules, especially the creation of a preliminary artificial anus. While chronic sigmoiditis may sometimes be cured by a simple medical treatment, colostomy is advisable. When diverticulitis is associated with the chronic sigmoiditis, resection preceded by colostomy is efficacious. When salpingitis is present, by first treating it a simple chronic sigmoiditis may also be cured; if diverticulitis also is present, however, resection is usually necessary, the formation of an artificial anus being valuable as an additional precaution.

Expulsion of Placenta Before Birth. Barrelet.—p. 828.

Benzene Derivatives of Intestinal Putrefaction in Etiology of Cancer.—Grandjean directs attention to the fact that cancer frequency is greatest among peoples with a comparatively high standard of living and to the fact that more than 63 per cent of cancers affect the digestive organs; this indicates that the diet has an etiologic influence. Among peoples with a lactovegetarian diet, such as the Hindus and many primitive peoples, cancer is much less frequent than in countries where the foods provide large quantities of proteins, especially those of animal origin. The author points out that the benzene derivatives of intestinal putrefaction resulting from diets rich in animal proteins exert a continuous growth stimulation on the healthy cells and gradually the constantly irritated tissues develop into malignant tumors. However, it is not only in the digestive organs, particularly the intestine, that benzene derivatives are formed as the result of protein putrefaction; on the contrary, they develop wherever in suppurative processes disintegration of protein by anaerobic bacteria takes place, for instance in the lungs, in the female genitalia, in abscesses of the teeth, in alveolar pyorrhea and in ulcers. The theory that the benzene derivatives are of significance in the etiology of cancer is also proved by the fact that occupational cancers are most frequent in workers who come in contact with benzene and coal tar products. To reduce the frequency of cancer, especially of the intestinal tract, it is therefore advisable to decrease to a minimum the intake of those proteins that form benzene derivatives; namely, meat, eggs and the plant proteins contained in legumes, such as beans, peas and lentils. The proteins required by the organism should, as much as possible, be supplied in the form of milk and milk products, because these give rise to a bacterial flora that is antagonistic to the bacteria of putrefaction. Regular defecation is likewise significant in the prophylaxis of cancer of the digestive organs.

Pleuropulmonary Complications of *Abdominal Diseases: Postoperative* Pulmonary Complications. E. Debenedetti.—p. 541.
*Fat Necrosis of Breast. R. Brancati.—p. 585.
Pathogenesis of Polycystic Kidney. L. Baccarini.—p. 618.

Fat Necrosis of Breast.—Brancati describes fat necrosis of the breast, a disorder consisting in a process of destruction and replacement of the fat tissue—which may be clinically confused with tumors and especially with cancer. He cites the various pathogenic theories, attributing to the influence of a pancreatic secretion or of a lipase contained in the blood changes in the fat due to endocrine disturbances, chiefly of the thyreo-ovarian group or of the reticulo-endothelial system; to this may be added the traumatic factor, which sometimes escapes observation. The author describes the various anatomopathologic stages of the lesion—from the formation of a focus of necrosis associated, when there is a trauma, with hemorrhagic foci, down to the formation of special nodules consisting of fibroblasts, giant cells and epithelioid cells (lipoblasts), which fill up the interior of the fat lobules, gradually dissolving the fat and finally replacing it with fibrous tissue. In the giant cells and in the lipoblasts one can discover, by means of special stains, some drops of fat. The author holds that these elements are derived from the histoid cells of the reticulo-endothelium, with which they are in intimate connection, rather than from an endogenic proliferation of the fat cell. For the differential diagnosis, one must note the respects in which the condition differs from cancer, for which there are few clinical symptoms. The best means is represented by the direct anatomopathologic test with the aid of an exploratory incision. In other diseases, such as tuberculosis of the breast, syphilis, actinomycosis and benign tumors, the opportunities for differentiation are greater. The treatment, provided it is possible to establish a sure diagnosis, should consist in the partial removal of the tumefaction. The author describes three clinical cases that he observed, during the past two years, at the surgical clinic in Rome. By means of macroscopic and microscopic pictures he reproduced the various aspects of the lesion.

*Modifications of Opsonic Index in Children Convalescent from Measles and Chickenpox. G. A. Piana.—p. 828.

Opsonic Index in Children Convalescent from Measles and Chickenpox.—Piana has made a special study of the opsonic index in children convalescent from measles and chickenpox. He concludes: The opsonic index in children convalescent from measles is diminished toward the typhoid bacillus, normal with reference to *Brucella melitensis* and increased with respect to the streptococcus. The high index toward the streptococcus, in contrast with that toward other micro-organisms, may be associated with unknown causes or etiologic affinities. The opsonic index in children convalescent from chickenpox is notably increased toward all three micro-organisms.

Congenital Cardiopathies, with Especial Reference to Their Importance in the Field of Scientific Medicine. V. Uguccioni.—p. 881.
Observations on a Number of Cutaneous Tuberculin Tests. P. Gorini.—p. 899.

Blood Changes in Chickenpox.—From his hematologic study of fourteen cases of chickenpox, carried out during the various periods of the disease, Carrara points out the following: in the period of incubation, relative lymphocytosis with neutropenia; in the exanthematic period, leukopenia in 50 per cent of the cases and constant relative lymphocytosis with neutropenia; absence of eosinophils in eight cases and increase of mononuclears in ten cases; almost constant observation of plasma cells (from 1 to 4 per cent); occasional observation of myelocytes and neutrophil metamyelocytes; in convalescence, reactive leukocytosis, which, often however, begins before the disappearance of the exanthem. During the various periods, the erythrocytes appear to be slightly or not at all modified. The author thinks that these blood manifestations may constitute a valuable aid in the differential diagnosis, especially in clinically doubtful cases.

*Absorption of Calcium and Phosphorus in Experimental Rickets. F. Peola and G. Guassardo.—p. 583.

Absorption of Calcium and Phosphorus in Experimental Rickets.—Peola and Guassardo performed animal experiments in which they used a loop of intestine, isolated by means of a double Vella fistula, to determine the absorption of calcium and phosphorus and its variations during the development and evolution of rickets. They also determined in the same animals the quantitative variations in the calcium and phosphorus contents of the blood serum after intestinal absorption under both conditions (normal and in rickets). The experiments were made first when the animals were in normal condition and then during the development and evolution of experimental rickets produced by Mellanby's diet. The moment when the phosphorus began to diminish was considered as the first symptom of rickets. This symptom was promptly followed by the appearance of clinical symptoms of rickets as proved by roentgen examination. The authors give the technic of their experiments and present the results in tabular form. It is manifest that the absorption of calcium does not undergo any variation during the entire period of rickets. The authors say that this fact confirms the opinion that calcemia is normal in rickets, except when the latter is complicated with tetany. The absorption of phosphorus, on the contrary, undergoes marked modifications, especially in the advanced period of rickets. Under normal conditions the absorption of calcium is from 50 to 60 per cent of the amount taken in, and that of phosphorus from 70 to 80 per cent. After experimental rickets has been provoked, the absorption of calcium remains normal while that of phosphorus falls to 60 per cent. However, the disturbances in the absorption of phosphorus appear retarded in rickets. Hence they should be considered from the point of view of the pathogenesis of rickets, as secondary manifestations.

Sulpharsphenamine in Treatment of Erysipelas in Infants: Case. J. B. Germano.—p. 256.

Helminthologic Study of One Hundred Appendixes.—Continuing previous studies that he made on the parasitology of normal appendixes in children, Bacigalupo now presents the results of an helminthologic study of 100 pathologic appendixes which had been removed by surgery from adults. Parasites were found in twenty-five (in twenty-four, *Enterobius vermicularis* and in one, *Trichuris trichiura*). In the case of *T. trichiura*, the parasite existed alone. In the other cases the number of parasites varied from one to seventeen in each appendix. In eighteen appendixes there were only female parasites; in five appendixes there were males and females in association, and in one appendix there was only one male. The author describes the technic he used to isolate the parasites. He reaches the following conclusions: The incidence of appendicular helminthiasis in Argentina in normal appendixes of children less than 13 years is from 27 to 48 per cent, and that of pathologic appendixes removed surgically from adults is about 25 per cent.

*Appendicular Spirochetes. S. Mazza.—p. 464.
Diverticulitis of Sigmoid Flexure. L. Puccio.—p. 468. C'cn.

Severe Hepatitis with Abscesses Following Appendicitis.—Tagliavacche and Brouca describe a case in which after an appendectomy the patient showed all the usual symptoms of severe hepatitis with abscesses. Yet he was cured by a simple treatment consisting of epinephrine, hepatic refrigeration, vaccination, daily enemas, and a diet of cereals, milk and cooked fruit. The authors believe that surgical treatment of hepatitis with multiple metastatic abscesses accompanying appendicitis is usually of value only when the operation is performed simultaneously with the appendectomy and by a surgeon especially skilful in determining the course of action to take in the face of unexpected complications. They also believe that more cures than is commonly admitted are spontaneous rather than the result of surgical intervention. Their policy, therefore, is to employ surgical intervention usually only as an early prophylactic treatment, when the hepatic complications are observed at the time of the appendectomy. Appendicitis likewise results at times in a single abscess of the liver which is much less dangerous and more susceptible to spontaneous cure than are multiple abscesses. This fact the authors consider an additional reason for believing that the hepatic complications with abscesses following appendicitis, still generally believed to be fatal in the majority of cases, are often cured spontaneously if no surgical intervention is practiced.

Appendicular Spirochetes.—Mazza examined the contents of 394 appendixes and in thirty-eight found spirochetes resembling those of the type *Spirochaeta eugyrata*. Most of the patients in whom the infection was observed had shown no previous indications of diarrhea or dysentery, nor had these spirochetes appeared in the feces. Microscopic examination of the thirty-eight appendixes revealed intrafollicular hemorrhages, intense eosinophilia of the submucosa, and in some cases chronic fibrous lesions and mucosal atrophy resulting from the coprostasis. The infection is doubtless due to some outside source, probably drinking water. Because of the lack of marked clinical or anatomicopathologic phenomena, there is no authority to speak of "spirochetal appendicitis" but merely of "appendicular spirochetes." In case the removal of the appendix does not remove all traces of the infection, arsenical treatment may be used. Because of the failure of attempts to cultivate these spirochetes it is impossible to say conclusively that they actually belong to the type eugyrata, although their morphology indicates this relationship.

Biliary Peritonitis Complicating Choledocholithiasis.—Masciottra and Ambrosino state that their fatal case of biliary peritonitis complicating a choledocholithiasis in which operation had not been performed is the first published in the literature. Their patient, aged 40, had the first attack four years before the last one. The next attack appeared two years later. In the present (third) attack the patient presented a grave syndrome with fever, intense jaundice, symptoms denoting obstruction of the common bile duct and insufficiency of the liver, and abundant hemorrhages from the uterus and the nose. Duodenal tubage and lavage of the stomach caused the expulsion of a large amount of black fluid. Medical treatment failed. At necropsy there was found a diffuse biliary peritonitis. The gallbladder and common bile duct were enlarged but not ruptured and they contained stones. One of the stones embedded in the common bile duct had caused its obstruction.

Primary Sarcoma of Lung in Child.—Acuña et al. report the case of a child, aged 8, observed during life, in which at necropsy a primary sarcoma of the left lung with invasion of the pulmonary vein, displacement of the heart, and metastasis to the liver, were found. The authors review the literature and present statistics on primary and secondary neoplasms of the lung observed during a period of ten years. Neoplasms of the lung are rare in persons aged less than 20. Sarcoma of the lung in children has an insidious onset with anorexia, cough and fever, without modifications in the nutrition of the patient. Later on the cough becomes worse and dyspnea and cyanosis appear. The physical signs, which at first are similar to those of pleural effusion, soon become more marked. Displacement of the adjoining organs takes place at the same time that thoracic deformity occurs. Roentgen examination shows a dark shadow in the lung. When roentgen pictures are taken at intervals of a few days, the rapid progress of the tumor, invading the normal fields, is manifested. Pleural puncture yields bright red blood. The last mentioned sign is characteristic of malignant neoplasm of the lung and in the authors' case it was present. Some of the symptoms found in sarcoma of the lung in adults (such as the expectoration of prune juice sputum, pain in the thorax and the appearance of neoplastic cells in the sputum) are not observed in sarcoma in children.

Orchitis After Vaccination in Child.—Schiavone says that orchitis is a frequent complication of certain infections. A type of orchitis similar to orchitis variolosa has been observed after vaccination. There are opinions (though conflicting) maintaining a relation between the epidermotropic virus of smallpox and of vaccination, on which basis it could be accepted that orchitis and orchiepididymitis might be complications of vaccination just as they are complications of smallpox. The author reports a case of postvaccinal orchitis (probably associated with epididymitis). The presence of an infection or the association of any other disease was excluded in his case. Orchitis developed six days after vaccination as a vaccinal complication. The author considers that there is a relationship between the development of orchitis in his case and the presence of complications of a similar nature in smallpox; that is, a relationship between postvaccinal orchitis and orchitis variolosa.

Air Embolism.—Rettig is convinced that the dread of air embolism is justified by the deaths that have resulted from filling the urinary bladder, the pelvis, the bed of the kidney, the chest and the abdomen with air. The use of oxygen has not lessened this danger. The author feels that the incidence of air embolism has been overstated, but, nevertheless, the fact that it does occur should never be forgotten. Dangerous diagnostic procedures should therefore be employed only when the indications are incontrovertible—when all other aids have failed, and the condition of the patient absolutely calls for making the diagnosis. The treatment is entirely prophylactic: when it is evident that air embolism has occurred, the injection of air should be discontinued, the patient should lie down with the hips slightly elevated, oxygen should be administered and the heart action should be supported, if necessary, with resort to the injection of epinephrine and even heart massage and artificial respiration with the pulmotor. Surgical intervention is useless. Rettig calls attention to the dangers of making an intracardiac injection; namely, the possibility of injuring one of the coronary arteries or its branches.

Treatment of Suppurations of Hand and Fingers.—Sokolov advises early operation in all these cases, under light general anesthesia in an absolutely bloodless field. The tourniquet should be applied to the upper arm. He never uses sharp hooks, nor does he resort to exarticulation. In cases of suppurative tenovaginitis, early intervention and subsequent immobilization (rest) of the extremity are of vital importance to complete recovery of function. Bandages and dressings must be applied with extreme care so as not to cause pain, and active motion is essential to the prevention of adhesions.

Wound Healing Under Adhesive Plaster Bandage.—Experience has convinced Dabasi that both the number and the virulence of bacteria are lessened under an adhesive plaster bandage. In the course of the treatment the underlying tissues reach a state of alkalosis in most cases. In 100 cases treated in this wise there was not a single complication nor a spread of the infection. Wound healing progressed very favorably. In fact, the author stresses the importance of moisture in favoring wound healing and points out that even pus is of value in that respect, provided it does not contain harmful elements, especially bacteria. Here the adhesive plaster bandage is of value because of its effect on the bacteria and without hindering wound secretion, which is needed to promote healing. Furthermore, it is cheap, is applied easily, is taken off easily, and never causes the patient any pain. It should be changed every ten or twelve days, at the latest; he prefers to do this every four or five days. The duration of the treatment varied from fourteen to thirty days, instead of months or even years, and the scar is less disfiguring than with the treatment usually employed. The method should not be used in cases of progressing suppurations; that is, when there is an evident tendency to spread, which calls for more radical measures.

Calcium Content of Blood in Chronic Rheumatic Arthritis.—A personal study of thirty normal, healthy students with reference to the calcium content of the blood has convinced Bastos and Mazo that the normal value is much more stable than has hitherto been supposed to be the case. This value lies between 10 and 11 mg. per hundred cubic centimeters; that is, the fluctuation is not greater than 1 mg. per hundred cubic centimeters. An examination of thirty-two cases of rheumatic disease showed lower and higher values and a greater fluctuation in the calcium content. The figures were: low, 9.99 mg.; high, 13.76 mg.; fluctuation, 3.77 mg. per hundred cubic centimeters. The low figure was obtained in only one case; in thirteen cases average values were obtained, and in eighteen cases there was a distinct hypercalcemia. The authors are of the opinion that these higher calcium values are not the result of storage of calcium in the blood but are indicative of changes in the bones which are a part of the clinical picture in some of these cases. In other words, there is a mobilization of organic lime in exostoses, bone bridges and ossifications. Other, uninvolved parts of bone are correspondingly decalcified. In cases of arthritis without bone lesions, the calcium values are normal. In eight cases of tuberculous ostearthritis the calcium values were well within normal limits; in two cases of bone cysts, they were markedly high (13 mg.); hence, it is evident that increase in calcium is not the cause but the result of these disorders. One bone area demands calcium for ossification; therefore it is withdrawn from some other area to supply this demand.

End-Results of Operations for Perforated Peptic Ulcers.—Neller has had opportunity to reexamine twenty-one patients on whom he had operated for a perforated peptic ulcer. He has also reviewed the literature for similar cases reported by other operators. The total number of cases reviewed was 579. Of these 374 patients, 64.4 per cent, were free from any discomfort. As to the effect of the type of operation on the result: 63 per cent of those on whom a gastro-enterostomy was performed, in addition to closing the perforation by suture, made no complaint, and 61 per cent of those without gastro-enterostomy were symptom-free. Neller feels that resection of the ulcer is the best procedure so far as permanent results are concerned, but because of the severity of this operation it is indicated only rarely—when it can be performed easily, when the condition of the patient is good, and if performed soon after the perforation has taken place. As a rule, or rather as a routine treatment, closing the perforation and performing a posterior gastro-enterostomy, gives the best results.

Results of Nitrous Oxide-Oxygen Anesthesia.—Von Klimkó prefers this anesthesia to any other. He has employed it in more than 300 cases, including laparotomies, done for various reasons, even a resection of the stomach, amputation of an extremity, herniotomy and cholecystectomy. He says that it has many advantages over general anesthesia: it is given easily; the patient does not mind taking it; he wakens quickly afterward and has fewer postanesthetic discomforts; it has no bad effects on the air passages or viscera in general. Postanesthetic bronchitis and pneumonia are exceedingly uncommon. However, the anesthesia is not sufficiently deep for laparotomies and it is more expensive than other means of anesthesia.

Effect of Reaction of Diet on Bone Regeneration.—Young animals from the same litter were used by Mondry and Boeminghaus to study the effect of distinctly acid and alkaline foods on the course of bone regeneration and growth. Note of growth was made by means of roentgenograms taken at eight day intervals. There was not much difference in result, but sufficient to make it evident that an acid diet does affect bone growth favorably, and that it may be well to bear this in mind in the treatment of fracture cases. Animals fed oats showed far better bone growth than animals fed greens. A clinical application of these observations can be made.

Treatment of Postoperative Retention of Urine.—In the opinion of Rotthaus, the intravenous injection of 0.01 Gm. of pilocarpine and 0.3 mg. of atropine is the best treatment for this condition. It is harmless, simple and effective. It is preferable to using the catheter.

Symptoms of Duodenal Ulcer.—Hoffmann remarks that acute ulcer of the stomach and duodenum often manifests itself with a variable symptomatology. Deep seated ulcers initiate the clinical picture with most severe pain in the upper part of the abdomen—such as occurs previous to the perforation of an ulcer—but disappears entirely in the course of a few hours. Less deep seated ulcers give indefinite symptoms; often only pressure pain on deep palpation over the site of the ulcer. In other words, the acute picture is absent. In the diagnosis of an acute duodenal ulcer, Hoffmann relies on the presence of fever and glycosuria, both of short duration, and motor disturbances in the stomach. He regards these symptoms as being almost pathognomonic.

Syphilis of Mammary Gland.—Akaiwa says that the female breast may be the seat of any of the clinical manifestations of syphilis. Gummous mastitis occurs either as a circumscribed or as a diffuse lesion. In his case, the gumma was detected eleven years after the occurrence of the primary infection. The macroscopic and microscopic observations are characteristic, although often a differential diagnosis is rendered difficult by resemblance of the tumor to other types of tumor. The author extirpated the tumor in his case and followed this removal with active antisyphilitic treatment. A complete cure and restitution of the patient's health was effected.

Treatment of Cancer of Breast.—Himmelmann and Lehmann report 271 cases of breast cancer (234 new cases; 37 seen because of a recurrence or a metastasis); 11.9 per cent of these cases were combined with struma. Some of the patients were subjected to radical operation alone; others to radical operation, plus postoperative irradiation with the roentgen ray. The results of the former method were better than those of the latter. The prognosis of tumors situated in the sternal half of the breast was worse than in the case of tumors situated laterally. The authors do not favor postoperative irradiation.

Excision of Gastric Ulcer.—An experience with ten cases leads Hoffmann to conclude that excision of a gastric ulcer is the best method of treatment. It is preferable to gastro-enterostomy.

Primary Hemangioma of Spleen.—The spleen in Schwarz's case weighed 3,500 Gm. It consisted almost entirely of a tumor which measured 24 by 18 by 10.5 cm. It was a typical hemangioma. The patient, a woman, aged 35, made a complete and rapid recovery, leaving the hospital three weeks after the operation.

Etiology of Appendicitis.—Heile is of the opinion that during digestion an increased amount of fluid finds its way into the lumen of the appendix, either directly from the intestinal contents or as the result of a reflex action of the sympatheticus. This fluid becomes strongly alkaline and has a strong tryptic action. If for any reason this fluid cannot make its way back into the cecum, it exhibits an irritating effect on the mucosa of the appendix wall. In the course of time the mucous glands in the wall of the appendix become necrotic. This effect is hastened by increase in the enzyme content of the contained fluid; its mixture with the normal bacterial content of the appendix; adhesions, torsion of the appendix; development of fecal stones, and increase in pressure within the lumen. Prophylactic treatment consists in avoiding overfeeding or overeating, especially of albuminous foods, and in good evacuation of the intestines.

Treatment of Gastro-Intestinal Lymphogranulomatosis.—Sussig reports a case of gastric and two of intestinal lymphogranulomatosis in which the pathologic changes were limited to a part of the gastro-intestinal tract and the regional lymph nodes. A tuberculous basis for this condition was absolutely ruled out; in one case a diphtheroid bacillus gave rise to many important questions. Therapeutically, the author is of the opinion that radical extirpation of the affected tissues is indicated with medical and roentgen treatment after the operation.

Draining the Liver and Bile Passages.—Mandl and Rissak have determined experimentally that it is not possible to drain the deeper lying bile passages in the liver by any type of drain; in fact, such a drain hindered the outflow of bile. Therefore, the operation of deep hepatostomy is indicated but seldom, only in most urgent cases. On the other hand, superficial drainage should always be employed in any operation on the bile passages when these show evidence of being dilated. Some clinical experiences cited support these experimental observations.

Blood Sugar Curves in Inflammations of Gallbladder.—Eitel has found that in cases of inflammation of the gallbladder the peroral administration of dextrose is always followed by a definite increase in the blood sugar; in fact, three distinct curves were recorded, each curve being typical of a single pathologic condition. Disturbed liver function is regarded as being the primary cause for these observations. It is not possible to detect disturbances of pancreatic function. With a return of hepatic function, dextrose is eliminated from the blood in two or three hours. The author feels that, in cases of chronic inflammations of the gallbladder which cannot be detected clinically, the sugar tolerance test may prove to have diagnostic value.

Ustilaginism, an Alimentary Disturbance in Children.—Mayerhofer observed two children with the typical symptoms of ergotism. In one case he noted convulsions and gangrene, in the other convulsions with delirium. The etiology of these conditions was at first not clear because the flour and bread used in the household did not contain ergot of rye. Moreover, both children had been fed almost exclusively with products of maize. Tests of the maize flour revealed a high content of *Ustilago maydis*, the smut of maize. The fact that *Ustilago maydis* contains substances that have the same pharmacologic action as ergot of rye indicated that the disease of the two children was caused by *Ustilago maydis*. The author designates the disorder as ustilaginism maydis. He gives a detailed description of the symptomatology and further discusses the diagnosis and the differential diagnosis. He says that most of the symptoms, with the exception of the cardiac disorders, namely, hypertension and tachycardia, disappear, after the food containing the *Ustilago maydis* is eliminated from the diet. However, the patients usually retain a hypersusceptibility to this substance. If food containing *Ustilago maydis* is not avoided, the disturbance becomes more severe, necroses develop, and the outcome might be fatal. Exposure to the hot rays of the sun may cause acute exacerbation of the ustilaginism. The administration of papaverine relieves the prickling sensation and decreases the high blood pressure. In order to prevent ustilaginism the author recommends that, in countries where maize is eaten in large quantities, the authorities should see to it that the maize used for seeding is free from *Ustilago maydis*.

Urethra: Suppository Anesthesia.—When a quantity of cocaine solution sufficient to anesthetize the urethra is introduced into it, tears of the mucosa are produced and the cocaine enters the systemic circulation and causes symptoms of intoxication. In at least one case reported in the literature the cocaine intoxication produced in this manner caused the death of the patient. Fryszmann therefore anesthetizes the urethra by means of oil of theobroma suppositories 6 cm. long and 4 mm. in diameter containing 0.3 Gm. of solid procaine hydrochloride, which is equivalent to 15 cc. of a 2 per cent procaine hydrochloride solution. Just before it is used, the suppository is placed for a moment in warm water (or a warm solution of mercuric oxycyanide); it is then introduced at once into the urethra and massaged in the direction of the posterior urethra. In about twenty minutes the anesthesia reaches its maximum depth and the introduction of instruments is completely painless. This method of anesthesia, which the author has used in a large number of cases, has the following advantages: 1. The mucosa of the urethra is not stretched and torn and procaine hydrochloride solution does not enter the blood stream. 2. With it one avoids the annoying and occasionally harmful compression of the glans penis while waiting for the solution of procaine hydrochloride to act. 3. The melted oil of theobroma facilities the introduction of instruments.

Treatment of Malignant Tumors of Bladder.—Stutzin believes that the thermocautery deserves greater use in the treatment of malignant tumors of the bladder. He reports the case of a man, aged 54, who had had hematuria for two months. Illumination of the bladder was almost impossible because of the rapid collection of blood in it. A pale blue fluid was therefore injected into the bladder and it was then possible to distinguish a broad-based, villous tumor that occupied the entire space between the orifices of the ureters and the neck of the bladder. The profuse arterial hemorrhage continued despite the use of various chemotherapeutic substances and an extensive coagulation of the tumor. The condition of the patient became grave. A suprapubic cystotomy was therefore performed; the tumor was destroyed completely with the thermocautery and its base was coagulated. The hemorrhage stopped immediately. The condition of the patient improved markedly and he gained in weight. On the basis of the results he obtained in this case the author recommends for the treatment of malignant tumors of the bladder a combination of cauterization, which acts rapidly but superficially, and electrocoagulation, which acts more slowly but more deeply.

Chemocoagulation of Bladder Tumors.—According to Joseph the great advantage of coagulation of bladder tumors by means of concentrated trichloracetic acid is that it acts much more rapidly than thermocoagulation. Another advantage of this form of treatment is that parts of the tumor that are not coagulated frequently undergo spontaneous retrogression; this does not occur following thermocoagulation. For chemocoagulation only a one-way ureteral cystoscope is required. The crystals of trichloracetic acid are heated without the addition of water and dissolve in their own water of crystallization. In this manner a clear liquid is produced that recrystallizes in the cold; to prevent this, a drop of glycerin is added for each cubic centimeter of trichloracetic acid. The ureteral catheter through which the acid is applied to the surface of the tumor is shortened considerably so that the acid does not crystallize out and occlude it. The tip of the catheter is cut off obliquely in such a manner that the opening points anteriorly. Since the acid in its concentrated form is much heavier than the bladder contents, the catheter is held closely over the tumor. At first the water in the catheter and bubbles of air escape and then drops of trichloracetic acid appear, drop down on the tumor, and in a few seconds (much more rapidly than with thermocoagulation) cause a large part of the tumor to become necrotic. Even hemorrhages are frequently arrested by application of the acid. Emphasis is laid on the fact that not more than one cubic centimeter of the acid should be used because of the danger of a too extensive necrosis of the tumor and of an acid intoxication of the patient.

Periurethral Urinary Phlegmon Following Operation.—Stutzin reports a case of periurethral urinary phlegmon in a man who had been treated for stricture. Several incisions were made in the greatly swollen genitalia and because of an impermeable stricture a cystostomy was performed. The condition of the patient improved but three days later he complained of pain in the neck. After a few days there developed an enormous swelling involving the right cheek, the right half of the neck, and the premaxillary and submaxillary spaces. Because of marked edema of the glottis with dysphagia and dyspnea, it was necessary to operate at once to save the life of the patient. The subfascial spaces of the neck were opened by means of a long incision and were found to contain a cloudy fluid but no pus. The operation was followed almost immediately by a disappearance of the edema of the glottis, but two weeks elapsed before the tissue included in the phlegmon became necrotic and was evacuated. In a review of the literature the author was unable to find the report of another instance of the concurrence of a urinary and a cervical phlegmon.

Zentralblatt für Chirurgie, Leipzig

57: 2225-2288 (Sept. 6) 1930

- Benign Tumors of Gallbladder. A. Pytel.—p. 2240.

Phrenicus Exeresis with Resection of Scalenus Muscles.—Els is convinced that a combination of these two procedures is vastly superior in therapeutic effect to exeresis alone, if the tuberculosis is limited to the upper portions of one lung, when pneumothorax is not indicated or not possible because of adhesions and it is desired to effect a shrinking of the lung; when complete collapse of the lung after pneumothorax is prevented by adhesions in the upper zone, thus making it impossible for the walls of a cavity in that part of the lung to come in contact; in certain tuberculous processes which do not exhibit any collapse tendency, and when thoracoplasty is performed as a further means to ensure complete rest of the affected lung.

Successful Operation in Case of Megacolon.—A woman, aged 22, ever since birth had suffered from severe constipation. Sometimes she would not have a bowel movement for three weeks. Finally, at about the age of 17 she began to suffer from much abdominal distress; the abdomen increased greatly in size; she complained of severe colic, vomited, became dyspneic, and when she did not have a bowel movement for six weeks, Ege was consulted. Roentgen examination revealed that the entire large bowel, especially the sigmoid, was enormously dilated. It filled the pelvis. In size, the sigmoid resembled an eight months' gravid uterus. The sigmoid and one half of the descending colon was removed; end-to-end anastomosis was performed. The resected part of the bowel was 35 cm. long and 11 cm. in diameter. The patient made a good recovery. She is entirely well and is free from any discomfort. The author emphasizes that while this girl should have been operated on in her early youth, the result is sufficient to warrant performing the operation even later in life with every hope of success.

Effect of Lead on Isolated Uterus.—Devlet-Kildeeva and Raikhstein noted the frequent occurrence of sterility, abortion, premature labor and various catamenial disturbances among women working in the lead industries. To study the effect of lead on the uterine muscle, they excised, under chloroform anesthesia, a part of the uterine cornu in cats and placed it in Ringer's solution or Locke's solution kept at 38 C. and through which a constant stream of oxygen was being passed. One end of the uterine specimen was fixed to the glass container; the other end was attached to a needle, by means of which the muscular contractions were registered on the blackened paper of a revolving drum. After the normal type of the muscular contractions had been ascertained, lead acetate was gradually added to the solution. The uterine contractions changed with the concentration of the lead acetate. In the first group of experiments, with less than 1:70,000 of lead acetate in the solution, hypotonia of the uterus and weakening and slowing of the muscular contractions were recorded; in the second group, with the increase in the concentration of the lead acetate in the solution up to 1:7,000, the muscular contractions increased in strength and frequency, and the uterus became hypertonic. In both groups the uterine reaction was of short duration, and the uterine contractions became normal in from ten to fifteen minutes. But in the third group, with the increase in the concentration of the lead acetate up to 1:200, the uterus reacted by a complete tetanus, and the muscular contractions could not be made to reappear even after all traces of the lead acetate were washed out. The reaction of the isolated uterus was constant and of the same type in the nulliparous, multiparous and pregnant cats. The introduction of the lead acetate solution into the blood stream of the cats also produced a hypertonic condition of the uterus.

Alkalinity of Blood in Eczema.—Bikkenin and Yasnitsky studied the p_H of the urine and of all the blood in fifty-six patients with eczema (twenty-seven acute cases and twenty-nine chronic cases). At the preliminary examination of the sympathetic nervous system, vagotonia was observed in fifteen patients, sympathicotonia in three patients, mixed form in seventeen patients and normal sympathetic nervous system in twenty-one patients. The determination of the p_H was made by the calorimetric method of Michaelis with a morning specimen of the blood and urine. No deviation from the normal was found in the urine, but the p_H of the blood was found to be from 0.1 to 0.5 above the average, with the maximum increase in the patients with vagotonia.

*Head's Zones as Aids in Diagnosis. L. Peterson.—p. 607.
*Frequency of Dementia Paralytica in Helsingfors from 1904 to 1928. G. E. A. Rothström.—p. 633.

Head's Zones as Aids in Diagnosis.—Peterson says that the zones of hyperalgesia belong to the easily perceptible symptoms that can be read directly from the patient and may be of valuable assistance in diagnosis, particularly to the beginner.

Frequency of Dementia Paralytica in Helsingfors.—Rothström says that comparison of the number of cases of dementia paralytica in men from 1919 to 1923 and from 1924 to 1928 shows an increase of about 100 per cent. The relation between the number of men and women with dementia paralytica was 3.7 to 1 in the first period and 5.8 to 1 in the second. He did not find evidence for the assumption that the nature and intensity of an antecedent antisyphilitic treatment affects the duration of the latent period or causes a shifting in either positive or negative direction. Thirty-two per cent of the cases now set in after the age of 46.

Studies on Jaundice. T. Geill.—p. 761. C'cn.
*Gastric Ulcer: Two Cases. C. Kirkegaard.—p. 767.

Gastric Ulcer.—Kirkegaard's cases illustrate the difficulty in differential diagnosis between ulcer and cancer when the changes in the wall of the stomach are so extensive as to point to the diagnosis of inoperable cancer on laparotomy. Niche formation, particularly with large niches, is held as an indication for operative treatment. In the first case, with a microscopic diagnosis of chronic gastric ulcer, the niche formation was so marked that the possibility of healing seemed doubtful. In the second instance the roentgen picture and earlier operative results clearly indicated a considerable defect, but the niche wholly disappeared after ulcer diet.

*Pathogenesis of Exophthalmic Goiter with Relation to Reid Hunt's Reaction. P. Vogt-Møller.—p. 773.

Pathogenesis of Exophthalmic Goiter with Relation to Reid Hunt's Reaction.—Vogt-Møller's hypothesis is as follows: In persons with "hyperthyroid constitution," increased thyroid hyperfunctioning occurs either on the basis of the generally recognized causes of exophthalmic goiter (to which wrong diet must perhaps be added) or without such cause. Through the sympathetic the increased amount of hormones in the blood leads to a disturbance of the renal functioning which to a greater or less degree hinders the elimination of thyroxin or closely related substances, thus further increasing their accumulation in the organism. Possibly the immediate cause of exophthalmic goiter—the toxins and so forth—may influence the kidneys directly as well as through the thyroid and play a part of the development of the symptom complex of exophthalmic goiter, or this may perhaps also be related to the reduced destruction of thyroxin.

*Symptomatic Changes in Blood in Nervous Diseases. G. E. Schrøder and A. Nyfeldt.—p. 813. C'cn.
Pirquet's Tuberculin Reaction as Cause of General Cutaneous Phenomena. A. Kristjansen.—p. 820.

Wassermann Reaction in Experimental Syphilis in Rabbits.—In rabbits with syphilitic infection (testis inoculation) Thomsen and Christiansen found that a marked positive Wassermann reaction developed regularly from five to six weeks after infection and continued unchanged for a longer or shorter time, occasionally six months, apparently independent of the further clinical course of the infection. After a certain time the reaction, often suddenly, ceased to be positive, even in cases with marked secondary pathologic conditions.

Symptomatic Changes in Blood in Nervous Diseases.—Schrøder and Nyfeldt say that while the results of their hematologic and psychiatric-neurologic diagnoses, in an ambulant material, do not show that certain neurologic conditions or psychoses are always connected with changes in the blood picture, further investigations are encouraged.

*Symptomatic Thrombopenic Conditions in Childhood. Y. Åkerrén.—p. 405.
*Postoperative Deaths from Heart Failure. A. Westerborn.—p. 417.

Symptomatic Thrombopenic Conditions in Childhood.—Four cases are presented by Åkerrén. In the first, in an infant with extensive sinus thrombosis, there was marked thrombopenia, which apparently shows the diagnostic significance of thrombocyte examination in this condition. In the second case, an acute aleukemic lymphadenosis, the only pronounced hematologic symptom was the atypical blood picture, almost normal except for a marked thrombopenia. In the last two cases, of rheumatic fever with cardiac disease, with transient thrombopenia and hemorrhagic diathesis, the thrombopenic stage was preceded by an increased thrombocyte count. Thrombocytosis and thrombopenia may thus appear as different phases of the reaction of the organism in infectious diseases.

Postoperative Deaths Due to Heart Failure.—In Westerborn's material of 15,642 operative cases there were 901 postoperative deaths. In his opinion forty-six (about 5 per cent) of the patients died from cardiac insufficiency, and thirty-nine (almost 5 per cent) more from complications resulting from cardiac and vascular weaknesses. Operative interventions should, if possible, be particularly avoided in patients with heart disorders due to chronic myocarditis, fatty degeneration and arteriosclerosis. To disclose such cases, further refinement of the diagnostic procedure is desirable, but application of present methods, especially roentgen examination and the so-called function tests, as well as an exact heart history, will exclude a number of cases in which the patient is unable to withstand the added strain on the heart imposed by operation and the attendant measures. Postoperative deaths due to poor heart function most frequently occur in older persons.
